Manufactured Iron and Steel.—There is no change in the state or prospect of the iron and steel trade. Both are dull, and likely to remain so. Prices are nominal. Iron ship plates are at £6; angles, £5 17s. 6d.; bars, £6 2s. 6d. per ton, less 2½ per cent. on trucks at works; steel ship plates, £7; ship angles, £6 17s. 6d.; rails, heavy sections, £5 per ton f.o.t. at works, less the usual discount. The Eston Steel Works have resumed work, but on short time.

NEWCASTLE, 14th May, 1890.

The Iron Trade.—The demand for the various descriptions of finished iron continues to be of an extremely limited character, consumers being apparently determined to confine themselves to barely supplying current needs. Thin sheet iron appears to be the specialty most in request, and the firms which are engaged exclusively in the manufacture of this article have still enough work to keep their machinery fully going. In the forges the pressure of work which was noticeable a few months ago no longer exists, and in a few instances the evidences of coming slackness are very apparent. Foundries, however, are still pretty busy, though in most cases the work in hand consists of orders received several months ago, and which had to wait their turn to be dealt with. Galvanisers are busy, and chain and anchor works continue to be kept in steady operation.

Shipbuilding.—There is now a second yard on the Tyne which has the whole of its building berths empty, this being the Edwards Company's Yard, Howden, from which the last vessel was launched a few days ago. Messrs. Schlesinger, Davis, & Co., the other firm who are in the unenviable position of having no vessels on the stocks, are understood to have received an order for three or four vessels of a small type, and their establishment may consequently be expected shortly to resume its customary activity. The Tyne Shipbuilding Company have three large vessels on the stocks, and the only vacant berth will shortly be occupied with the keel for another. Builders are at present free from labour troubles, but the necessity for reducing wages will possibly soon arise, and it is to be feared that the peaceable relations now existing will then be difficult to maintain.

Protective Paints for Ships.—Messrs. Holzapfel are now placing on the market a special paint for preserving iron and steel decks, called their "special black soapstone composition." It dries in an hour, and covers a very large surface. Judging by several trials it appears to be the very thing required by shipowners.

The Coal Trade.—Lower prices are now being quoted for most descriptions of coal, but the tendency to lessened value is, of course, most conspicuously shown in connection with the house coal trade. The shipments of coal and coke at Tyne Dock for the week ending May 10th amounted to 120,938 tons, being an increase, as compared with the shipments in the corresponding week last year, of 23,808 tons.

BELFAST, 14th May, 1890.

Shipbuilding and Engineering.—Work in all the shipyards here continues good. There were two launches during the last week, and the stocks are already re-occupied by vessels of large tonnage. The riveters in Messrs. Workman, Clark, and Co.'s yard, who have been out on strike for the past two weeks for a rise in the piecework prices, have returned to their work again on the old terms. Messrs. D. & W. Grant have almost completed their contract for four of the bridges for the new City of Dublin Junction Railway. Three of the bridges have been already delivered, and the fourth will soon be ready to leave the contractors' yard.

The New Straight Channel to Belfast.—This huge work is now nearly finished. The erection of the light-houses, which will be three in number, has been commenced, and it is expected that the channel will be open for traffic in a few months. There will be a depth of 17ft. of water at low tide, and, besides enabling large vessels to reach the port at all times, it will shorten the route up the Lough by about one-half.

Linen Trade.—The market still continues stagnant, and the turnover would fall decidedly short of production. Prices, however, remain steady, and a more hopeful feeling exists in some quarters. Stocks generally are not large, and were it not for the prevailing anxiety to keep selling, there is no reason why higher prices should not be obtained. Yarn purchases have been small, and confined to the supply of immediate requirements. Goods have not been much inquired for except special makes, but the existing contracts will keep the manufactures from going into stock for some time to come. The production of handloom goods still continues miserably small.

IMPROVED DOUBLE BAND SAW MACHINE.

CONSTRUCTED BY MESSRS. JOHN WATTS & Co., MACHINISTS, BROAD WEIR ENGINE WORKS, BRISTOL.

(*For description see page* 461.)

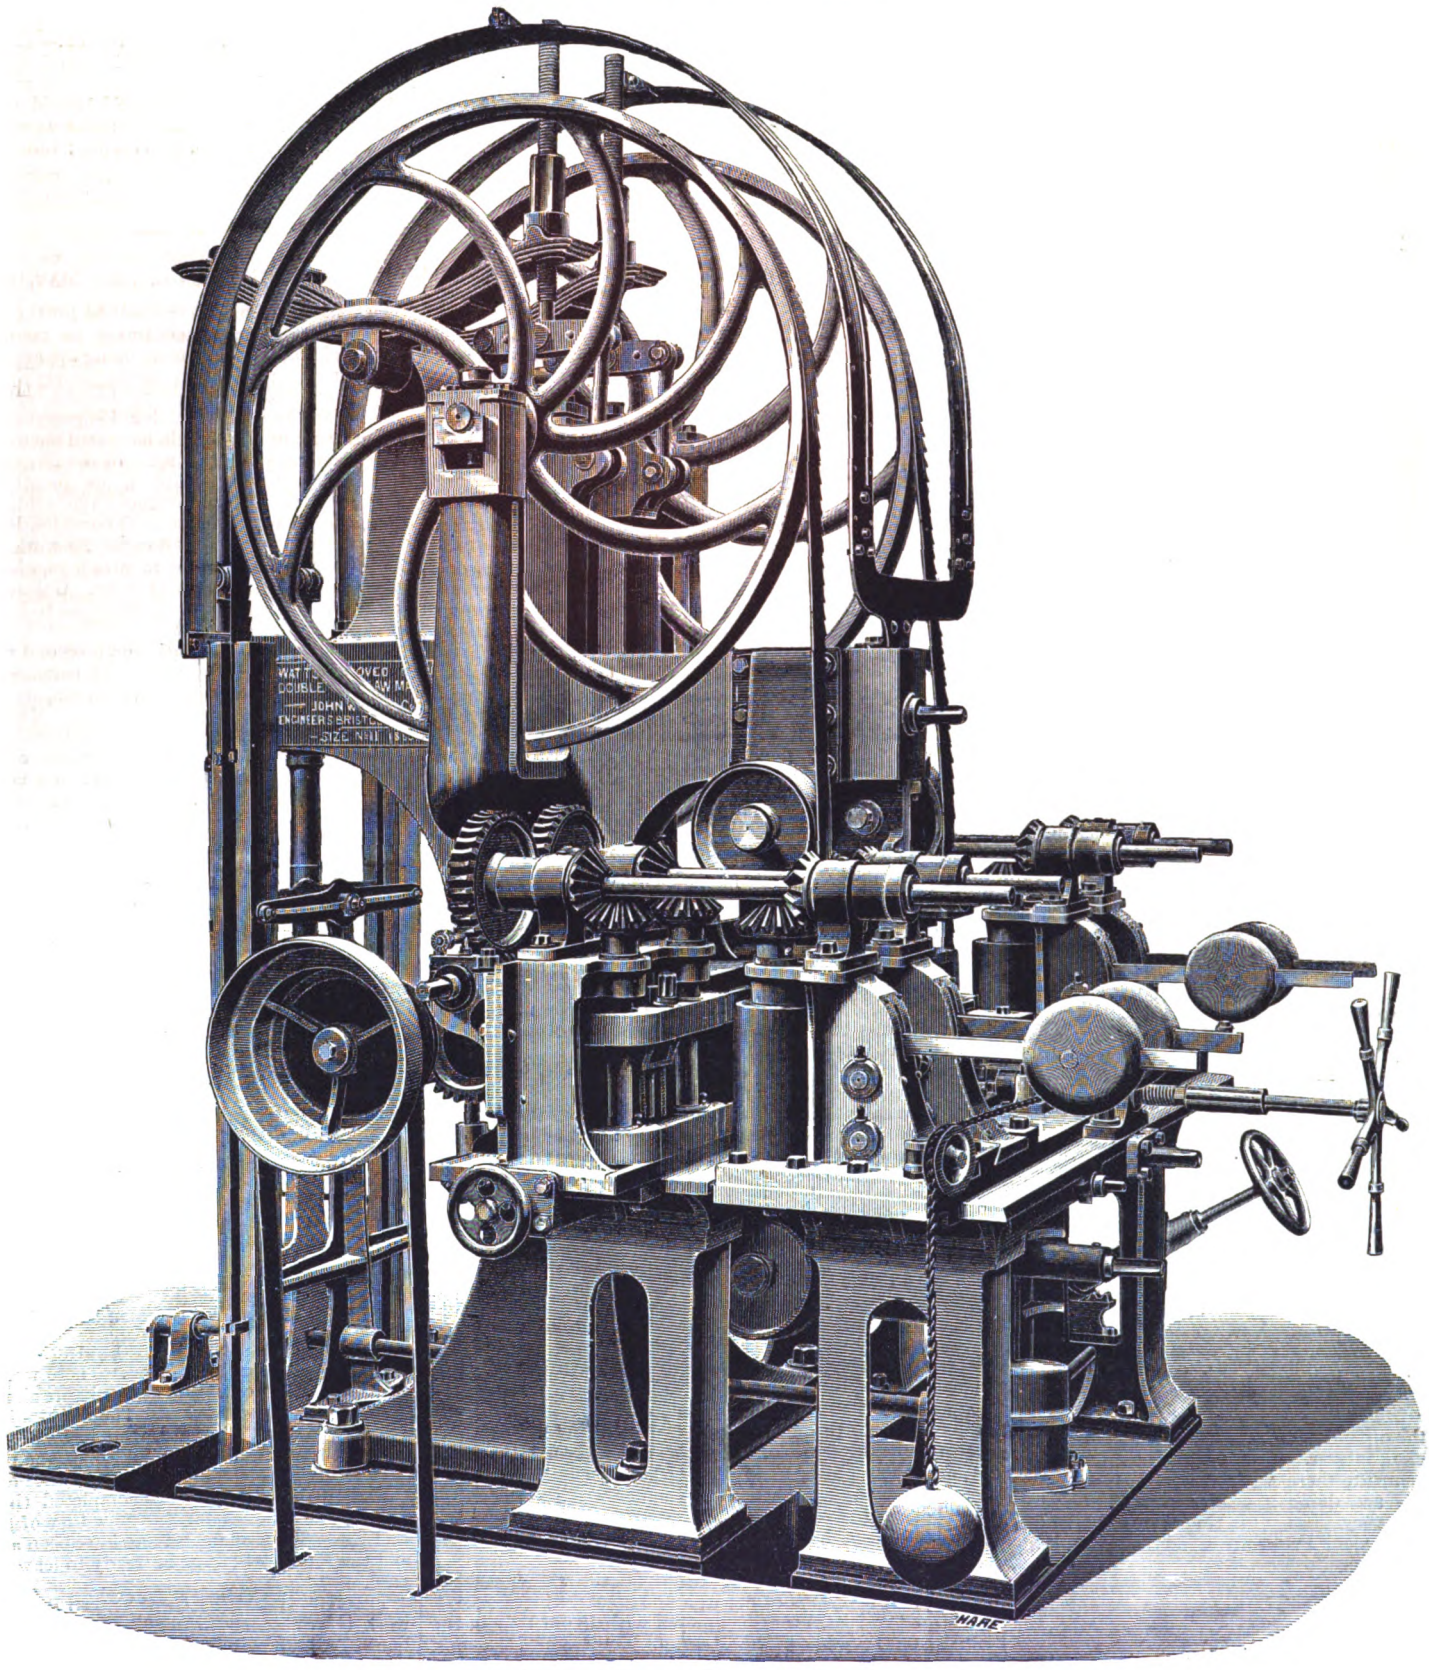

FIG. 3.—GENERAL VIEW OF MACHINE.

INSTITUTE OF MARINE ENGINEERS.

A MEETING of the Institute of Marine Engineers was held on the 29th ult., at which Mr. J. D. Churchill read a paper on the "Churchill" Marine Governor. He remarked that, as by far the larger percentage of breakdowns occurred in fine weather, or in weather which could not be described as rough, the necessity for having a governor attached to the engines, always in operation, became apparent. By having such a governor fitted risks of drainage to the rest of the machinery, in the event of a breakdown to one portion, were reduced to a minimum. Cases were cited where, on account of shafts breaking, the engines—relieved of the load of driving the propeller through the water—increased in speed, and caused serious damage. It was pointed out that generally the governor fitted to a marine engine was too small, and was placed in such a position that it was difficult to keep it fit for service.

The discussion was entered into by a large number of members. The remarks all tended to show that, as a rule, the governor and connecting gear did not receive that attention which the importance of the subject warranted. One or two of the speakers spoke very highly of the Churchill governor, which, in their experience, had been found to give excellent results in practice. It was remarked, very forcibly, that the governor was frequently badly fitted, and placed in a position dangerous of access. Thus, when the governor belt is designed to run close to the engine-room bulkhead, the engineers have to go below the platform into the bilges to place the belt on the pulley.

At the meeting of the Institute on Tuesday, the 6th inst., Mr. R. E. Crompton read a paper on "Electrical Engineering," in which he gave a full account of all the various types of dynamos, and the details of their construction. Mr. Crompton was listened to with great interest.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week.

All accounts are payable to GEO. CAWLEY, *358, Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

CAN AN IMPROVED EDUCATION PREVENT STRIKES?

A STRIKE is undoubtedly, in one form or another, a very ancient institution, the origin of which is lost in the mists of antiquity. Probably the earlier strikes were those of slaves or soldiers, and generally partook more of the character of a revolt or mutiny. The refusal of mercenaries to fight so long as their pay was in arrears might justly be considered as a military strike, and such an occurrence during the Middle Ages was by no means uncommon; but as long as the majority of labourers were in the position of serfs or slaves, industrial strikes, as we now understand them, were practically impossible. A refusal to work would have been looked upon by the masters as rebellion, and promptly treated as such, and the heads of the mediæval Burns and Tillet, in the company of those of their more prominent followers, exposed in some convenient place to the public gaze. Under these conditions, a strike, to have any chance of success, must necessarily take the form of rebellion pure and simple. The strike of which the present and preceding generations have experience is, however, essentially a modern development, and, owing to its frequent occurrence within the last twenty-five years, has come to be regarded almost as a necessary accompaniment of industrial activity. It is now, we believe, hardly disputed that the artisans of this country have, on the whole, improved their condition by combination and occasional strikes; but few, and least of all the artisans themselves, are apt to consider how much of their success, in the long run, is due only indirectly to their own action, while it has been rendered possible by the operation of agencies which, as a rule, they have done their best to thwart and oppose. Paradoxical as it may seem, the material improvement in the condition of our wage-earning classes is, to a large extent, the result of the substitution of machinery for hand labour in industrial processes, and its continual improvement. But for this it would have been impossible, without eventual loss to the community, for the employer of labour to have granted the concessions demanded of him. As it is, in spite of strikes, and the not unnatural prophecies of disasters from the perennial croakers, the prosperity of the country has advanced and the welfare of the artisan has been promoted. The introduction of improved machinery to increase the productive capacity of the nation has, in many cases, met with opposition on the part of the workmen, and is still looked upon with distrust and aversion even by the more intelligent members. Yet it is quite obvious to those who are able to look beyond their own immediate and apparent interests, that the substitution of machine for hand labour must necessarily be to the advantage of the community, and, sooner or later, of all classes of labourers. Experience has proved this to be the case. For strikes have stimulated the manufacturer to increase his output by improved machinery and processes; strikes have insured to the operative a share in the advantages of increased production which might otherwise have benefited only the employer. As in so many natural processes, we have here an example of action and reaction. Had the action of the men not resulted indirectly in improved machinery, either a further advance in wages and reduction of the hours of labour must have long since ceased, or many of our industries by this time been irretrievably ruined. It does not follow that because hitherto the policy pursued by the trades unions has on the whole been successful, that it can be continued indefinitely without evil results. With few exceptions, a strike has always aimed at two objects—first, an increase of pay; secondly, a reduction in the hours of labour. It is very evident that, with the best conceivable machinery, in those classes of manufacture where mechanical appliances can be utilised to the fullest possible extent, absolute limits must sooner or later be reached, and these limits are the sooner reached in the presence of foreign competition. Up to a certain point the men may gain at the expense of the employers, but the margin for this gain is much smaller than is generally supposed; and if no compensation took place a simultaneous rise of wages and reduction of the hours of work would very soon remove employers from the scene of action. Unless the compensating action we have referred to keeps pace with concessions to labour, employer and employed, and with them the whole nation, must alike suffer by diminished production. The British working man is often apt to forget that wages must be earned by an equivalent production on his part. He frequently seems to have an impression that there exists, somewhere or other, a vast industrial goose, which only requires sufficient squeezing in order to lay an indefinite number of golden eggs, quite irrespective of any nutriment she may receive. The fact is ignored that this prolific bird requires a proportionate amount of food, and that this food must be the workman's own effective labour.

As regards hours of labour, there is undoubtedly for every class of work a certain daily period for which in the long run the performance of the average individual is a maximum; this period, however, must vary very considerably with circumstances. Where the work done is performed chiefly by machines of a more or less automatic character the production is much less dependent on the individuality of the workmen or attendants than in those industries where the labour is largely manual. It must not be forgotten, however, that a continual strain on the attention unaccompanied by physical exertion is of itself very fatiguing, and when exerted in the moist and close atmosphere of a spinning and weaving shed is probably as exhausting as, and certainly less healthy than, many kinds of outdoor employment demanding a constant expenditure of muscular energy. Certain of the trades union leaders have expressed themselves strongly against overtime, but it is extremely doubtful whether, if a *plébiscite* were taken, they would find themselves supported in this matter by the rank and file. We think it not unlikely that, with a very large proportion of the members of trades unions, the leading attraction in an eight hours working day is the greater opportunity it affords for "making overtime." Thus the candle is burnt at both ends and expected to become no shorter. Meanwhile, foreign competition increases, while foreign wages may not rise in the same proportion as those of the British workman It is a pity that those professional leaders, who are so ready to instruct their followers as to the iniquities of the capitalist, will not or cannot declare the full truth about foreign competition, and the extent to which the inhabitants of this country depend for their existence on foreign trade. So far from doing this, the typical professional leader rather prides

Digitized by Google

himself on indifference to imperial matters. What to him are India, British prestige, or British interests, if only he can secure the immediate object in view?

Piece-work is a fruitful subject of dispute between employers and employed, and officially the trades unions are generally very strongly opposed to it. To the uninitiated it may seem strange that a system which, on the face of it, is the fairest that could be devised, and by which, as a matter of fact, the highest wages are earned, should be regarded by artisans, as a body, with aversion. The first explanation that occurs to those who think about the matter is probably that the workman prefers taking things easy, on comparatively low pay, to obtaining good wages by high-pressure work. There is perhaps a little of this feeling at the root of the matter, but it is, we are inclined to believe, not the immediate cause of the aversion to which we have referred. Most employers, when they find that those of their men who are doing piece-work earn wages very considerably in excess of the average day wage for the same class of employment, reduce their piece-work rates, so that, as the artisan becomes more skilled and increases his production, he cannot obtain the full benefit of this increase. As a consequence, as we know from our own practical experience, artisans paid by contract purposely abstain from working to their full capacity. We have in our mind a case in which men engaged on a certain class of pattern-making always turned out on one particular day in the week at least double the quantity of work performed on any other day. As the time boards, with a record of the patterns made, were only given in once a week, this discrepancy in the daily achievements did not appear. Among the men themselves the day in question was known as the "making up day."

The state of affairs as regards piece-work in engineering workshops to which we have alluded results in a kind of hide-and-seek game between masters and men. Before fixing his piece-work rates in the first instance, the employer tries to arrive at some idea of what his men can do in a given time; he knows that the average artisan can get through without distress an amount of work considerably in excess of his daily performances on day wages; consequently, after making the necessary observations and calculations, the employer so arranges his contract prices that the artisan will have to work somewhat harder than before to earn the equivalent of his previous daily remuneration, but, on the other hand, the latter by exertion can easily make a good deal more. If, as frequently happens, this increment becomes with practice very considerable, the rate of pay is reduced, as already stated. If, while still on day wages, the workmen suspect that their output is being analysed in order to serve as a basis for contract prices, they will do their best collectively to hide their capacity for work under a bushel; lathes and other machine tools are run at somewhat lower speeds than necessary, articles require an unusual amount of "setting" in the lathes, tools get blunt very soon or break frequently and require much grinding, while the cranes and hoisting tackle are always engaged when wanted—in short, great ingenuity is displayed in wasting as much time as possible without its being too apparent. Of course experienced foremen and managers, having gone through the same mill, know these little manœuvres, and discount them as far as possible. We are inclined to the opinion, however, that the whole matter stands on an unsound and, we may even say, immoral basis. On both sides there is what amounts almost to sharp practice, and the only true remedy is greater candour and hearty co-operation. There is to all industrial affairs a moral as well as a material aspect, and the former is, as we have often pointed out, as important as the latter, while both are intimately connected.

An increased sense of responsibility, and a distinct realisation of the extent to which our continued prosperity must be dependent on foreign trade, are things greatly to be desired on behalf of the wage-earning classes. Whatever well-meaning enthusiasts may preach, there is very little doubt that for a very long time to come the struggle for industrial existence among nations must continue, and that the strongest will prevail. In our own country, however, much may be done to mitigate the asperity of the conflict both between individuals and classes, and we believe that the Boards of Arbitration, originally suggested by us, and since taken up by the London Chamber of Commerce, if judiciously managed, may prove powerful instruments for effecting this desirable end. Let it not be thought, however, that we would wish to abolish competition within healthy limits; it is good for the human race that the fittest should survive, and what is more, in spite of all efforts, Socialistic or otherwise, to crush out individuality, the fittest will survive.

THE RAILWAY RATES INQUIRY.

The inquiry on the revised classifications of merchandise traffic, and schedules of maximum rates and charges, proposed by the various railway companies under the Railway and Canal Traffic Act, 1888, which has been most exhaustive, was brought to a close at the beginning of this week. The inquiry was divided into two parts, the one dealing with rates, terminal charges, and general conditions, and the other solely with classification. The former, to which we have already referred, lasted no less than sixty-eight days, and each side—that is, the traders and the railway companies—were represented by counsel. The other part took eleven days, and, as a rule, the cases were conducted by the goods managers of the railways, and by delegates of various trades, this portion of the inquiry being of a more technical character.

The procedure in dealing with the classification has been as follows:—The railway companies deposited with the Board of Trade a schedule of all the various articles which they carry, the schedule being founded on the Clearing House list, but with numerous alterations, omissions, and other modifications. The classes are denoted, A, B, C, 1, 2, 3, 4, 5, in ascending order of rates, Class 5 being the highest. Copies of the schedule were furnished to all who were interested—*e.g.*, the various chambers of commerce and numerous trading associations. Where it was considered that any article was classed too high, or was improperly defined, or had been omitted, objections were lodged setting forth the classification in the present Clearing House list, the class in the deposited schedule, and the class proposed by the objector, together with statements in support of the objection. To these the companies replied, in some cases conceding the class asked for, but generally making a defence for the deposited schedule. Conferences were held in a few cases between the traders and the railway companies. The objections with the replies were printed, and were taken in alphabetical order for discussion. The alphabetical order, while convenient for reference to the notes, greatly increased the difficulty of insuring the attendance of the delegates of the various trades. The procedure of the Court consisted generally of an opening address by one or more traders in support of some particular objection. Elucidatory questions were put by Lord Balfour and Mr. Courtenay Boyle, sometimes developing into a close examination. One or more of the representatives of the railways followed, supporting their printed replies, and were generally subjected to questions by the Court. Occasionally a considerable discussion arose, and finally the trader had a right to reply. Though, as a rule, it was not evident in which direction the Court had been influenced by the evidence and arguments—their duty being to make a report, not to give a decision—great satisfaction was expressed at the impartiality and perseverance with which the above-named gentlemen conducted the inquiry. They frequently assisted a trader who was unaccustomed to a position combining that of a counsel and that of a witness, and made amends for his ignorance of the art of pleading, by putting very pertinent questions to the railway companies.

From the shorthand notes might be extracted interesting statistics of nearly every trade, accompanied, as is too seldom the case in such literature, with a considerable amount of criticism. Thanks to Mr. Courtenay Boyle's inquiries, a new Child's Guide might be compiled from this source, for no strange commodity, such as "kentledge," "kainit," "carferel," "divi divi," "matchetts," "munjeet," or "babool," was allowed to pass without a brief definition, generally supplemented by an account of its uses and value per ton. The principal points on which the Court thought that the classification should be decided were—value in proportion to weight, bulk, risk, and damageability. The market values were constantly challenged by the railway companies, who did not always appear to improve their cases by such assertions as that £10,000 per ton might be taken as the value of gloves, because one pair, weighing an ounce, cost 4s. 6d. to 5s., or by calculating the value of a truckload of Epsom salts from the price quoted per lb. in the price list of the Army and Navy Stores.

It is impossible to give an idea, within the limits of our space, of the nature of the arguments or of the probable result of the inquiry, but we must express our surprise that so many trades failed to put in an appearance when their cases came on. So important an industry as that of the tea trade could surely have afforded to keep a representative to watch their interests, and to have given some better statistics of the comparative value of tea and coffee than can be obtained from a stores price list, which appeared to carry but little weight with the Court. Printing ink, boots and shoes, and several other articles were unrepresented by any trader, and had to be dealt with by the assistant secretary of the London Chamber of Commerce, which body has most carefully watched the numerous interests of its members, both in the organisation of the objections and in the legal part of the case.

Much discussion arose on definitions. For instance, Are needles drapery or hardware? Where must the line be drawn between toys and musical instruments? It was suggested that "hardware" should be defined as "all that leaves Birmingham and goes into an ironmonger's shop." Drysaltery appears to be "all that a grocer sells except coffee, sugar, and tea." The Court were very anxious to come to some understanding on the subject of mixed parcels, but they could never get any trader to see the points on which they wanted to get an opinion. "Mixed drapery" and "mixed grocery" were entries of this character. It was suggested that an unscrupulous trader might open a parcel containing 1 cwt. or 2 cwt. of cloves, and put in 1lb. of soap, and then send it as "mixed groceries" at a lower class. For the want of a few words from an expert, "oxygen gas in approved bottles or cylinders" was classed as "dangerous."

The classification which will be settled upon as the result of this inquiry will be the statutory maximum which the railway companies will be allowed to charge, and will supersede all the special agreements which have hitherto been made. It is difficult to judge to what extent some traders were right in complaining that any increase in the rates would absolutely ruin their industry, or how far the railway companies are stifling their own business by placing such checks on their goods traffic.

THE CARLISLE RAILWAY ACCIDENT.

The report of Colonel Rich, the Board of Trade Inspector, has just been issued. We quote his judgment as follows:—

The collision was caused by the mismanagement of the engine-driver and consequent want of brake power to stop the train, which ran down the incline from Shap Summit, at a speed of about sixty miles an hour, and approached Carlisle Station at a high speed. If the engine-driver had obeyed his instructions, whistled for the guards' brakes, and kept the steam brake on his engine and tender from the time that he said he tested his automatic vacuum brake at Wood Bank, and thought it did not act, I am of opinion that he would have stopped his train before he reached Carlisle Station. The train was then more than two miles from the point of collision. I think that it must have been much nearer Carlisle, when he tested and thought that the automatic vacuum brake would not act. It is impossible to make the driver's evidence agree with what the train would or should have done under the circumstances stated, and more particularly so from what occurred when I ran an experimental train from Carlisle to Penrith and back, which was made up of similar vehicles, with similar brakes, and in the same manner. I found that, although the rails during my experiments were particularly dry, by keeping steam on the engine, I could run for many miles when the small ejector was shut off, and that, although the train vacuum pipe gradually leaked off to zero, the reservoirs only leaked off 3in. to 4in. of vacuum in about ten minutes, and kept the brakes on, but not tight on, and that the brake by this slow leaking on acted more on some coaches than on others. Although the ejector would blow up the vacuum to 22in., 19in. was the highest vacuum I maintained, and 17in. about the standard vacuum. The van wheels alone heated after running a considerable distance, although the friction as the brakes leaked on must have been more severe during my trials, when the rail was perfectly dry, than on the morning of the accident, when it was dropping sleet and rain, and was considerably warmer at the north than at the south side of Shap Summit. When I made a very quick stop at the north side of Penrith Station, I observed that the driver shut off his small ejector at once, and on asking him why, he said they were directed to shut it off

Digitized by Google

in the large stations to prevent noise; but on my remarking that the train was not at a station, I gathered from his reply that it was his practice to do this. It appears to be the rule to do so. This rule should be altered and the practice discontinued.

Taking this practice into consideration, I think the accident was caused in the following manner:—The engine-driver shut off his small ejector on arriving at Shap Summit, and forgot to open it before proceeding on his journey. If so, the brakes would gradually and partially leak on, but they would not stop the train on a steep falling gradient, while the engine was steaming hard, and particularly on a greasy rail, such as existed on the night in question. When the driver tested his vacuum at Wood Bank, there would be little or none in the pipe, he would feel no further check to his train than was already applied by the leaking on, and the guards would find the same when they tried to apply the vacuum brake by opening the valves in their vans. The driver then became anxious, and instead of carrying out what his rules directed him to do, and whistling for the guards' brakes, he took out the pin, and altered his lever so as to work simple vacuum instead of automatic. By doing this, he took off whatever brake power he had left, except the steam-brake on his engine and the screw brakes on the vans, which may not then have been applied by the guards, and he also must have taken the steam-brake off his engine during the time when he first tried to obtain automatic brake power by blowing up his vacuum with the large ejector, and before he took out the pin. He appears not to have whistled for the screw-brakes until he got close to the station, but the guards put them on when they were at Upperby Bridge Junction. After the train stopped, the wheels of two coaches were found to be heated. They must have been so heated while running with the automatic brake on between Shap Summit and Wood Bank, as there was not time or brake power put on between Wood Bank and Carlisle Station to heat them. The same effect would have been produced by the vacuum-pipe between the engine and tender becoming stopped with a plug of ice after the train left Shap Summit, but in this case the automatic brake would have leaked on, and could not have been taken off by the driver so long as the ice remained, and I think that, as the driver shut off steam at Wood Bank, the train would have been stopped with this brake power, the guards' screw-brakes, and the steam-brake on the engine and tender before it reached Carlisle.

When the automatic vacuum brake machinery was examined after the accident it was found to have been in good order. About half-a-pint of water was found in the belly of the pipe between the engine and tender, but this quantity of water, if frozen, would not be sufficient to plug the pipe and stop the air-way. From the evidence of the signalman it appears doubtful whether the engine-wheels were braked when the train passed the station and the signal-cabins at the south side of the station. This would be the case if the engine-driver had only pulled his lever into the notch in the slide, instead of pulling it right over, as he said he did. If he pulled it only to the notch he would take the brake off his engine and every vehicle in the train, except those to which the screw-brakes were applied, which the witnesses who saw the train pass said was the case. I think that there was nothing the matter with the brake, but that the driver, by shutting his small ejector at Shap Summit, lost a great part of his vacuum, and that he did not notice this before he reached Wood Bank. He then got thoroughly confused, and omitted to do what he should have done if he had acted as his rules direct, and did what he ought not to have done, by altering his engine to work simple in place of automatic vacuum. I think that great allowance should be made for the mistakes that he made, as it must be a most confusing thing to have both the simple vacuum and the automatic vacuum brake to deal with. The simple is put on by pulling a lever towards you, and the automatic vacuum brake is put on by pushing the *same lever* from you. I recommend the London and North-Western Railway Company to put a stop to this confusion by doing away, as the company have some time since determined, with the simple vacuum as fast as possible, and I would further recommend the company, as they have now adopted the automatic brake, to carry this out in the best manner, and to work it with a proper amount of vacuum. The company now work it at an average vacuum of about 17in. This is not enough. It should be worked up to 25in., and not allowed to go below 20in. when running. This should be done by means of an air pump or an ejector. If done by an ejector the exhaust pipe should be taken through the boiler, which will prevent the steam condensing as it does when the pipe is outside, and drivers should not shut the small ejector while their engine is attached to a train. I understand that the London and North-Western Railway Company are now fitting their engines with air pumps. The drip trap, with a valve, should be placed at the bottom of a vertical down pipe, and close enough to the ash pan to prevent the valve freezing.

The driver of the Caledonian engine did what he could. He had fortunately time to reverse his engine and get steam on, to run in the same direction as the London and North-Western train, before the collision occurred. The conductor and guard with the London and North-Western train appear to have done their duty; and as to the state of their gauges, these would be affected by the driver's action in working his big ejector. When they opened their release valves to put on the automatic vacuum brake it was impossible for the brake to act, as the driver was pulling it off with his large ejector. I place no reliance on the driver's evidence as to the state of his gauge while descending the Shap. I think that he probably did not observe it till he wanted to use the brake when the train arrived near Carlisle.

I recommend that the crossing to the sidings at the north end of Carlisle Station should be reversed, so that engines may run directly across the main line when going to the sidings.

Letters to the Editor.

THE INSTITUTION OF MECHANICAL ENGINEERS.

To the Editor of "Industries."

Sir,—Referring to your preliminary observations in your last week's issue on the very interesting address of the President of the Institution of Mechanical Engineers, permit me to say that I commenced work as a railway engineer in January, 1852, and am therefore another living example who has had a long experience in railway work.

Yours, &c.,
Gorton Foundry, Manchester, 13th May, 1890. Thos. Hunt.

To the Editor of "Industries."

Sir,—With reference to the statements put forward in the report of the Research Committee of the Institution of Mechanical Engineers in your last issue, while being most interesting, I can hardly think there is that knowledge shown on the subject which one would be led to expect. The only marine member of the Committee strongly protested against one of the findings—that there was priming in the boilers of the "Tartar." There were none of the well-known evidences denoting such a state of things, and it seems to have been pure assumption to get out of the difficulty in this way. Of course, without a design of the boiler, one is in the dark on many points, but there is the protest that no signs were apparent of any priming. In view of doubts upon the matter, the Committee should certainly have published more facts to have borne out their contention.

What other explanation is there possible for the water which was found in the cylinders besides that of its having passed over from the boilers? Here, it must be remembered, that the steamer was running light, and not in the condition for which she was designed. Her boiler pressure, therefore, stood at its highest point, 141lb., whereas the admission to the high-pressure cylinder was only 121lb. There was thus a certain amount of expansion in travelling from the boilers to the engines. Then again, without diagrams to consult, it is not rash to suppose that the engines were linked up to their utmost, and wire drawing would follow. In short, the conditions all round appear to have been conducive to a want of economy, and especially to a possible formation of water in the cylinders. This supposition is certainly not more out of the way than many brought forward at the meeting, and may, therefore, be worthy of the attention of your readers. It would appear to be a matter of regret that the Institution did not see their way to have a preponderance of marine members at these trials; the value of the report would thus have been considerably enhanced. We have now the ludicrous feature that the one gentleman representing the marine branch is "staggered" at the findings in a report which he is supposed to have had a share in framing.

There may, of course, be more elucidation of the whole subject when further details are published. I cannot but think, however, that the Institution has done nothing towards advancing our knowledge of the design and working of marine engines, as one might have supposed, and with the opportunities obtained, they should have been enabled to do.

Yours, &c.,
London, 14th May, 1890. Marine Engineer.

COMPRESSED AIR TRAMCARS.

To the Editor of "Industries."

Sir,—I have carefully studied the letter of Messrs. Hughes & Lancaster, in your issue of the 2nd inst., and fear that they have hardly given full consideration to what they have written. I do not think that anyone except Messrs. Hughes & Lancaster would interpret a new roadway to indicate that new rails were required. The laying of a gas or water main, or their own 4in. air-pipe, does not involve a new roadway, they say, but a cable tramway and electrical systems with underground cables do. I wrote to you on this subject for information, and have gleaned something. For instance, that electric traction on the storage system requires a new roadway when the gauge is different. Where has the gauge had to be changed to suit accumulator cars? Certainly not at Barking, nor in New York, nor in Philadelphia, nor at Brussels. The line or lines referred to are unknown to me; but Messrs. Hughes & Lancaster can, doubtless, furnish the information.

Another interesting item of intelligence is that electric traction cannot hold out in America. Mr. T. C. Martin quite recently stated that at the present time there are running or building in nearly 150 American towns some 2,000 cars on about 1,200 miles of track. The mileage in operation is, I think, about 650 miles, and this does not much look like an industry which is shortly going not merely to cease but to vanish. I have before me the *Street Railway Gazette* of Chicago, a paper run in the interests of tramway men, and its items of news fairly bristle with paragraphs announcing the construction of new electric lines and the conversion of horse-power lines into electric lines. The Street Railway Company in Minneapolis has just thrown aside an unused cable plant that cost £80,000, and is putting on electric cars over 100 miles of road. From all this I should have judged that electric traction in the United States was in a healthy condition, but I bow to the superior knowledge of Messrs. Hughes & Lancaster.

I must, however, take exception to their theories of financial operations. It is utterly absurd to say that electric traction is being "boomed" in this country because the American lines are going to smash up. In the first place, such a course would be futile, and anything analogous is unknown in Stock Exchange transactions, peculiar though many of these are; and, secondly, there is no boom. "Bears" and "bulls" are both glad to pick up hints for new departures, and it would be of value if your correspondents would explain how these supposed efforts in Great Britain are to take effect on the dying concerns in the United States.

Only a few words more, and I shall conclude, but I have to point out that Messrs. Hughes & Lancaster speak of the trial on the Barking line in the past tense. Though they are "behind the scenes" as to American electric traction, they do not appear to be even in the auditorium as far as English traction is concerned. The Barking line, I may mention, is still at work. As regards the cost of running it, Messrs. Hughes & Lancaster suggest that it does not pay at 4½d. per car mile. Mr. Baines, on the other hand, asserts that it does. Authoritative information on this point ought to be given.

Yours &c.,
Portsmouth, 10th May, 1890. Car.

SUGGESTIONS FOR A NEW SCOTTISH MAIN RAILWAY SYSTEM.

To the Editor of "Industries."

Sir,—In reply to correspondent "M.," in your issue of the 9th inst., perhaps by this time he may have seen something more of the details of my scheme which appear in some of the Scotch papers to-day. They will, I think, answer his objections on some of the points which he raises. There are, however, others which I intend dealing with in a more amplified form than newspaper correspondence will permit of, but which I may now refer to shortly. The first is the high-level bridge over the Clyde. In proposing this bridge the remarks of your correspondent are just such as I anticipated; and in my condensed communication I was careful to point out that the navigable channel of the part of the Clyde to be crossed *is only 800ft. wide.* The remainder of the bed of the river, a mile wide at this point, is dry or nearly so at low water. The greatest rise of the tide is only 12ft. On first mention of a high-level bridge of the length in question, the idea of the Forth Bridge and its gigantic cost looms on the mind. There is, however, really no comparison in point of either difficulty or cost between the two. The crossing of the Clyde at Dumbarton is more to be compared to the crossing of a dry land valley by a structure of metal or masonry, or the two combined (of which there are numerous instances in this country and abroad), rather than a broad deep estuary such as the Forth. The two, therefore, will not admit of comparison in this respect. There is one point, however, common to both—that is, the suitability of the elevation of the banks on both sides of the Clyde for a structure of the kind.

A second objection is "that for Glasgow and the greater part of Scotland such accommodation would be entirely out of the way." A perusal of the article referred to will, I think, convince your correspondent of this erroneous impression, while bearing in mind that the proposed is essentially a west-coast route, and that Glasgow, so to speak, is essentially a west-coast place. Also that all the traffic from the north-west, the north, and part of the north-east, to Glasgow, the west of Scotland, and *vice versâ*, has to make a great detour toward the east coast. In my letter of the 25th ult. no mention is made of any other arrangement than the connection of the three northern railways with one system in the south. In the amplification referred to it is shown, that in the event of the Glasgow and South Western being confirmed in her suicidal policy, there are several other alternatives. One omitted may now be added, which, as far as this scheme is concerned, would save a high-level bridge, and make the communication between the north, Glasgow, and the south the most direct possible. It would be in the new main line being made to connect with the Glasgow Central Railway. This, besides giving more direct communication with Glasgow, would shorten the distance. It would also supply the Caledonian with what she desires to get, and has just missed getting, a line to the Leven Valley. It would also bind together and strengthen immeasurably her connection in all parts of the north, and especially in the North-West and Western Highlands, with the centre of her system—Glasgow. The adoption of all the proposals of this scheme would be a barrier, too, to designs which her rival has on the north-west. And if the North British are sustained in their action for amalgamation with the Glasgow and South Western, the Caledonian may fully put forth its claim to "gobble up" the remainder of the minor Scotch companies as a sort of balance of power.

The third objection to be dealt with is "the inevitable destruction of the beauty of the western shore of Loch Lomond." In this paragraph your correspondent uses a word for which I think something milder might be substituted. Although it is pretty much an understood fact that railway engineering as at present practised does interfere with romantic and solitary beauty, still there is no reason why it might not be mitigated, and that perhaps in a simple way. To my mind there is little that is inconsistent in the puff or streak of vapour issuing from the copse or being seen through "the lattice work of pines." If gone properly about such artifice might be so employed as to call forth commendation from even Ruskin himself as a blending together in nature of ugly utility and art for the good of mankind. Be this as it may, however, railway engineering "has something to answer for" in this respect in the past.

Yours, &c.,
London, 10th May, 1890. "Eon Strathaar."

MORISON'S EVAPORATOR AND FEED WATER HEATER.

CONSTRUCTED BY MESSRS THOS. RICHARDSON & SONS, HARTLEPOOL.

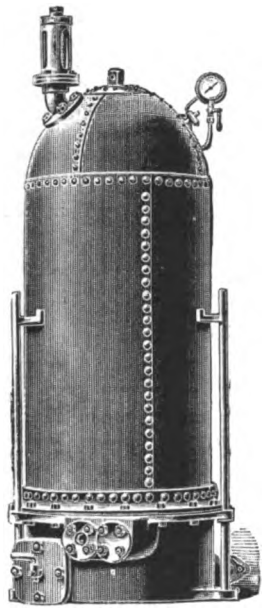

FIG. 1.—GENERAL VIEW.

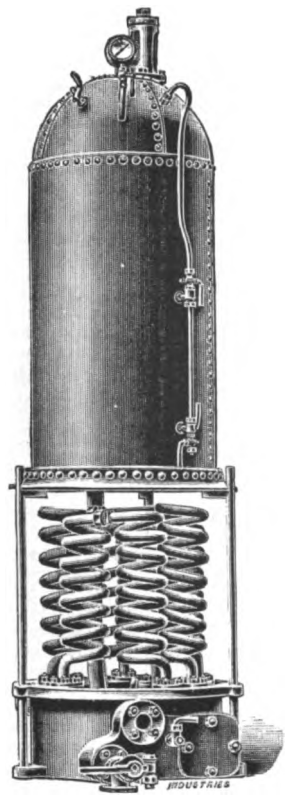

FIG. 2.—VIEW WITH SHELL RAISED.

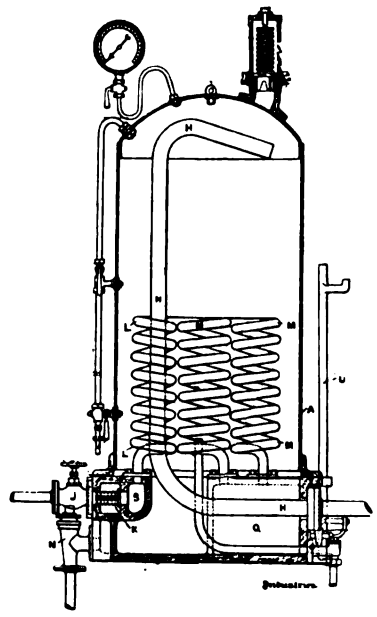

FIG. 3.—VERTICAL SECTION

MORISON'S EVAPORATOR AND FEED WATER HEATER.

THE necessity for skilled and careful attention in the management of marine boilers was never greater than with the present high pressures; for, although the utmost care may be taken in design and construction, a single voyage of careless working is sufficient to cause very great expense. The mismanagement of a boiler frequently results in collapsed furnaces, leaky tubes, decreased efficiency of the boiler as a steam generator, and consequent increased consumption of coal. In ocean-going steamers the loss of water due to leakage at the glands, &c., has to be made up by auxiliary feed, which is usually taken from the sea, and thus solid matter becomes deposited in the boilers. As the greater the evaporation on a given surface the greater is the deposit, the furnace crowns and back tube plates suffer from scale more severely than other parts of the boiler; and the undue formation of scale in boilers for triple and quadruple expansion engines must be recognised as a very dangerous element. It is, therefore, evident that to prevent such formation salt water must not be used as an auxiliary feed in marine boilers. The best method for making good the loss from leakage is to obtain a supply of fresh water by some convenient method, and various modes for purifying feed water have been proposed.

The combination evaporator which we illustrate above is an apparatus for giving this supply. In this apparatus salt water, which is obtained from the circulating pump discharge, is boiled, and the pure steam given off is condensed into water and pumped into the boilers as auxiliary feed water. Figs. 1 and 2 show general views of the apparatus, and Figs. 3 and 4 vertical and horizontal sections. The apparatus consists of a lower vessel, on which the heating coils L M and all the connections are arranged, and a dome-shaped shell or cover. The salt water to be evaporated enters through the non-return valve G, and is heated by means of steam which circulates through the pipes L M. The steam enters these coils through the valve J, and passes through the pocket S, first to the coils marked L, and then to those marked M. By the time it has arrived at the end of M it becomes condensed, and falls as water into the trap Q. A strainer K is placed in the pocket S in order to catch any dirt as it enters. The steam from the salt water enters the

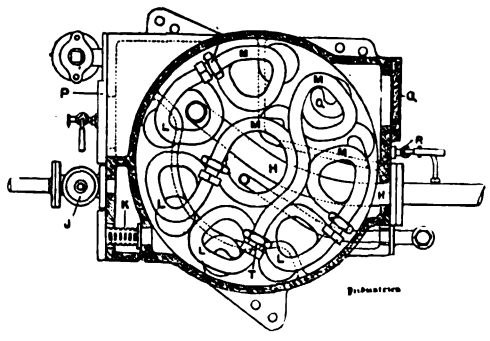

FIG. 4.—HORIZONTAL SECTION.

pipe H, and passes from thence to the condenser. The whole of the dome-shaped casing A may be lifted up along three iron guides U in order that the coils and inner parts may be got at, as shown in Fig. 2. The shell is made of Siemens-Martin steel, with a stamped steel lower ring riveted to it, which forms the flange which joins it to the lower part. The condensation of the steam formed by the evaporator may take place in the main condenser, or the evaporator steam may be arranged to mix with the steam condensed in the coils, and the whole passed through a special feed water heater (not shown in the illustrations), in which the heat is as far as possible utilised.

The whole arrangement is well worked out, and we understand has been fitted into over seventy steamers during the last six months. It is the patented invention of Mr. D. B. Morison, manager to Messrs. T. Richardson & Sons, Hartlepool, and is made by this well-known firm.

THE ROYAL SOCIETY CONVERSAZIONE.

THE Royal Society held a *conversazione* on Wednesday evening, in the rooms at Burlington House. The exhibits were as varied and as attractive as in past years, and the experiments and demonstrations were watched with great interest.

Perhaps the most interesting of all the experiments was Professor Roberts-Austen's illustration of the recent investigations of M. Osmond, on molecular changes which take place during the cooling of iron and steel. A mild steel rod was allowed to cool from 1,100° C., and when the temperature arrived at 750° C. and at 660° C. there appeared to be a temporary but distinct accession of heat.

No Royal Society *conversazione* is complete without some ingenious experiment by Mr. C. V. Boys. His oscillating spark experiment is a modification of the method employed by Dr. Oliver Lodge to show the oscillatory nature of a spark formed under proper conditions. Six lenses are mounted on a disc and are made to rotate. Each forms an image of the spark on a screen, which is drawn out by the movement of the lens into a broken band of light. The lenses are not at exactly the same distance from the axis, so that the band formed by one is not overlapped by the band formed by the next. Thus the whole duration of the spark from the first to the last oscillation may be observed or photographed. Mr. Boys also showed a series of photographs exhibiting the results of experiments intended to demonstrate the formation of drops.

Mr. Shelford Bidwell's experiment with a steam jet attracted much attention. The jet on being electrified cast a markedly deeper shadow, which assumed a peculiar orange-brown hue.

Professor Silvanus Thompson had a number of ingenious arrangements for the more effective carrying out of physical experiments. He also showed an ingenious colour experiment. Two liquids, incapable of mixing, are placed over one another in a flat bottle. They are chosen so that each absorbs all the rays that the other one can transmit. Though each is transparent, they are jointly absolutely opaque. They are also opaque when shaken up together.

Professor Norman Lockyer exhibited various spectrum photographs. As a result of investigations it is now shown that all parts of the spectrum can be photographed, that actinism is not peculiar to any part.

The exhibits shown by Dr. A. Geikie, the Director-General of the Geological Survey, were intimately connected with the subject of coal in the London district. A series of cores and specimens were shown from all the deep bores which, during the last thirty years, have been made in the South of England in search of water. Professor Judd showed some interesting specimens of minerals brought from Ceylon by Mr. C. Barrington Brown, of which the most attractive was an enormous beryl, weighing between 5lb. and 6lb.

The meteorological exhibits showed how increasingly important a place exact measurement is taking in scientific research. Mr. G. J. Symons, for example, showed a brontometer, or thunder-measurer. The object of the apparatus, devised jointly by Mr. Symons and the MM. Richard, of Paris, is to determine precisely the sequence of the various phenomena attending a thunderstorm, during which the barometer often rises and falls with puzzling irregularity.

Mr. D. Morris, of the Royal Gardens, Kew, exhibited a sugar-cane seed and seedlings. As the result of some experiments with self-sown seedlings, it is anticipated that, by cross fertilisation and a careful selection of seedlings, it will now be possible to raise new and improved varieties of sugar cane, and renew the constitutional vigour of plants that have become deteriorated through continuous cultivation by cuttings or slips. Great importance is attached to the subject in sugar-producing countries, as it opens up an entirely new field of investigation in regard to sugar-cane cultivation. Of equal practical interest was Professor Marshall Ward's exhibit of a selection of transparent photographs, showing—(1) the habit, &c., of various trees from different parts of the world; (2) the comparative structure and anatomy of several European timbers; and (3) some of the more prominent features of diseases of wood, &c., and fungi causing them.

Reviews.

AN ELEMENTARY TEXT-BOOK OF APPLIED MECHANICS By David Allan Low, M.Inst.M.E. London: BLACKIE & SON. 1889.

The name "Applied Mechanics" was introduced from the French when the science of engineering was still in its infancy, and was intended to show the applications of theoretical or rational mechanics to some of the ordinary problems of engineering. Rankine's well-known treatise gave it a position in scientific nomenclature, and it will be rather difficult now to get rid of it, when it has been rendered meaningless by the wide extension of engineering in all its departments. That treatise was really an introduction to the different departments of civil and mechanical engineering, and was largely incorporated in the special treatises which he afterwards published. On the other hand, there has been a growing tendency, which is right and proper, to introduce into books on theoretical mechanics a number of examples

Digitized by Google

taken from engineering practice, instead of the specimens of undoubted absurdity with which the older works abounded. In fact, the line of division between theoretical and practical mechanics has almost disappeared. This book of Mr. Low's is really a treatise on theoretical mechanics, in which the theory is restricted to what ordinary students require, and the examples chosen are from applications to the simpler machines, and will be found very useful in schools and evening classes, and the teachers can easily supplement the theoretical part where it seems to be wanted. We need not go over the contents of the book, which, in its scope, is very similar to others which have been published in recent years, but we commend it highly for its clear and concise arrangement and method of exposition, and for the large number of well-chosen examples which are to be found in it, and think it will be useful to a large class of students.

THE MARINE TRANSPORT OF PETROLEUM. A Book for the Use of Shipowners, Shipbuilders, Underwriters, Merchants, Captains, and Officers of Petroleum-Carrying Vessels. By George Herbert Little. E. & F. N. SPON, 125, Strand, London; New York—12, Cortlandt Street. 1890.

The work before us should assist in insuring greater safety to life and property. While the author disclaims any pretence to original research, he has not failed to compile practically all the information extant bearing on the subject. The book has, however, defects. Some of the woodcuts and description are very much like advertisements. Occasionally extraneous matter is introduced and exaggerated language used, which is not commendable in technical literature. As an example, ventilating fans are stated to be "not by any means a necessity, and are generally a source of trouble *and tribulation* to the engineers, *besides* taking a great deal of steam to drive them." "Marine engineers have a rooted and very natural objection to anything which revolves above the normal speed of marine engines, and fans which make from 200 to 700 revolutions per minute are a source of *vexation of spirit, besides* being very liable to give out." The phrase "vexation of spirit" also occurs in connection with the construction of ballast tanks.

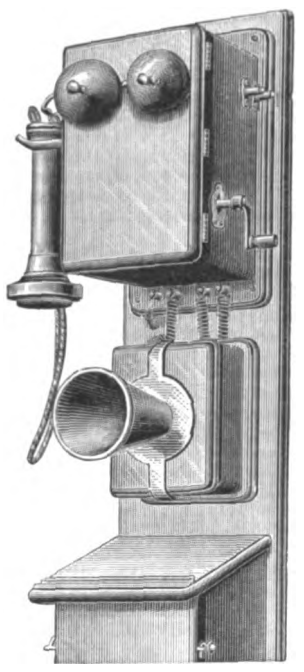
While the author has freely made use of papers read before technical institutions, and other works by Sir E. J. Reed, Mr. W. H. White, Chief Constructor to Her Majesty's Navy, Professor Jenkins, M.A., and Mr. B. Martell, there is much valuable advice offered to those in charge of petroleum vessels, resulting from the author's practical experience in the trade. As the author correctly states, "loading and discharging are the most dangerous times in the career of an oil-tank steamer," and, accordingly, he gives minute instructions as to the conduct of these operations. A matter which is not, however, referred to is the danger of pumping drainages from petroleum cargoes into harbours. This is a practice which should be strictly prohibited, as already it has occasioned considerable damage to several vessels by the oil, after being discharged into a river, being ignited.

There are seven chapters in the book, the first being introductory, dealing with petroleum generally, its forms, chemical composition, distilling, liability to explosions, &c. Very properly, the raising of the legal limit (from 73° Fahr. to 120° Fahr.) of the flashing point of ordinary commercial petroleum is advocated. A few pages are devoted to "Liquid Fuel," on which the author holds advanced views, stating, "it only requires the expenditure of a little enterprise on the part of shipowners, and the erection of astaki storage tanks at the coaling stations, to render its use possible on ordinary cargo and passenger vessels." Five explosions, including the "Petreana" and "Ville de Calais," are referred to. The risk of vessels carrying petroleum in bulk, due to the likelihood of being struck with lightning, is referred to; but in iron or steel built vessels the author states, "we may safely dismiss all fear of explosion of oil or vapour through the agency of lightning." The chapter concludes with an attack on the "low standard of education" of ordinary shipmasters.

Chapter II. deals with ship designing, stability, &c., and is written so that it may be comprehended by seagoing men. The author is apparently not himself if he is not severe, and enlivens what otherwise would be the most technical chapter by satire. Chapter II. is one of the best. A knowledge of the conditions requisite for the stability of a vessel are especially requisite when liquid cargoes are carried.

In Chapter III. the question of stability more directly concerning oil in bulk steamers is considered. Ballast tanks below the oil compartments are condemned, amongst the reasons given being that leakage into them causes a loss of stability due to the ballast tanks being only partially filled. Incidentally, horizontal oil-tight flats, in addition to longitudinal and transverse bulkheads, are advocated for the subdividing of large steamers. Professor Jenkins' inquiries into the stability of this type of vessel under various conditions are given at length, and the graphic results shown, and most of the principal designs of "tank" vessels illustrated and described.

Chapter IV. is devoted to pumps, loading, discharging, ballast tanks, and ventilation, and it is satisfactory, as it enters into the minutest details; and Chapter V., a brief chapter on "Testing," explaining the use of the hydrometer, and directing how samples of oil should be taken so as to obtain a correct mean specific gravity. Abel's tests are referred to, and a modification of the Abel tester suited for use on board ship illustrated and described.



In Chapter VI. the lighting of petroleum steamers by electricity is considered. No other form of illumination should be adopted, although even an electric light installation may become a source of danger. It is pointed out that good results cannot be expected from installations laid down by "marine superintendents," and it is recommended that "owners should engage an experienced electrician to test the circuits each voyage."

Chapter VII. consists of useful data and tables culled from various sources, and is succeeded by a brief vocabulary of phrases in English, German, and Russian used every day in the sea transport of Russian petroleum.

In future editions we would suggest that to the present index an alphabetical one should be added.

THE "AUDIO" TELEPHONE MOUTHPIECE.

THE particular advantage claimed by the inventors of this mouthpiece is that it is constructed in such a way as to intensify the sound waves, and thus render it possible to carry on conversations in an ordinary tone of voice. The mouthpiece is specially constructed for use in telephones of the Blake type, and the accompanying illustration shows how it is attached to the telephone.

The mouthpiece simply consists of a truncated cone which is clamped on to the telephone. By using an indiarubber ring between the mouthpiece and the telephone, any escape of sound is entirely prevented. The cone is double, the outer cone being perforated with holes, the idea being that the vibrations caused by the sound waves on the interior cone have full freedom and are entirely protected from contact with external substances. The Audio Telephone Mouthpiece Company, of 35, Ann Street, Glasgow, are the makers.

THE LANE FOX PATENTS.

WE have received a pamphlet containing reprints of reports by Sir William Thomson, Professor Perry, Mr. W. H. Preece, Mr. Latimer Clark, and Professor S. P. Thompson, on Mr. Lane Fox's Patent No. 3988 of 1878. Three of these reports are dated 1886, and the other two are not dated. They are supplemented by a statement signed by the patentee, dated April, 1890. These reports claim for Mr. Lane Fox the credit of the invention of the system of distribution of electric light by means of mains and branches to lamps arranged in parallel, and with secondary batteries. No one who has studied the history of the subject will contest this claim, but we think that it will be a surprise to many to learn that a patent of so wide a scope is in existence, and is still "alive." The question at once arises, Why has it been buried for these twelve years? Before the company which has been recently formed can claim a royalty this question must be answered. We understand that, with the assistance of Messrs. Drake and Gorham, Mr. Lane Fox has recently succeeded in regaining control of certain patents which have for several years been in the possession of the late Anglo-American Brush Co. That company never, as far as we are aware, ventured to claim any royalty for the parallel distribution of electricity. This does not prejudice the validity of the patent, but, if no such claim has ever been made, it seems somewhat doubtful if any retrospective action can be taken.

After making the first great strides in determining the true principles of high resistance, &c., which have made incandescent lamps practicable, and in suggesting the system of connecting them with the mains which has made their common use possible, it is to be regretted that the inventor's attention was turned to investigations of a very different character, for, whatever may be their value, the result has been that Mr. Lane Fox has received little credit and less reward for his brief but valuable work. An adequate remuneration for this invention, in the shape of royalties, either retrospective or prospective, would be an infliction to which the industry would not submit without a struggle, if for no other reason than that the claim has been made after so long a silence. The patent, if valid, has but two years and five months to run, and we hope that Mr. Lane Fox's company will lose no time in stating what course they intend to pursue. A modest fee, as claimed on far slighter grounds by the owners of the Jablochkoff patent for transformers, or that which is demanded for compound winding, is hardly worth resisting, though in both of these cases the inventors appear to have had little or no notion of the uses to which their inventions would ultimately be put; while Mr. Lane Fox was undoubtedly alive to the practicability of parallel distribution, in spite of the ridicule which he met from those who might be considered high authorities as to the value of his work at the time of his patent.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

At the meeting of this Institution on the 8th inst. a paper was read, "On Lightning Guards for Telegraphic Purposes and on the Protection of Cables from Lightning," by Dr. Oliver Lodge, F.R.S., of which the following is an abstract:—

The fact that the greater portion of a sudden flash prefers to jump an air space, rather than traverse a moderate length of wire, cannot be perfectly appreciated without recognising the rapid oscillatory character of sudden discharges, and the doctrine of impedance, or immense obstruction, which good conducting wires offer to currents of this character. This impedance may be of 100 or 1,000 ohms, whereas the resistance to steady currents may be but a ten-thousandth part of this amount. It is a matter of common experience that almost any lightning protector is better than none at all, and that the best of those in use are by no means inefficient instruments. They do not afford perfect security, but the occasions when they partially fail are perhaps not very numerous. It is therefore the practice to establish some sort of proportion between the elaborateness of the protector and the value of the apparatus to be guarded. In all except the very simplest and crudest form of protector, a perception of the true conditions may lead to more complete protection without necessarily much increase in cost. A number of obscure and unexplained faults develop themselves in the gutta-percha of submarine cables; it is possible that some of these are due to electric waves of high potential which have got into the core and punctured its dielectric at previously weak spots; and such faults are found occasionally to develop in the wake of a storm. I would also point out that the fact that a lightning switch is found damaged, or its wire perhaps fused by a flash, is no proof that it has entirely protected the cable from hostile influence. It shows that it has done the best it can; but since that best falls short of perfection, the damage to the protector, proving that there has been occasion for its activity, proves likewise that the cable has been in a position of danger, has received some proportion of the damaging current, and in all probability has suffered some amount of deterioration. The voltage which plays about in the very feeblest form of statical discharge is so enormously greater than anything ever developed by ordinary voltaic batteries that one cannot regard with equanimity the entrance of any portion of such electromotive forces into the delicate vitals of a cable. The assertion I have virtually made is that no conceivable form of single air gap, whether it be between knobs, or points, or plates, or wires, or between wire and tube, or coil and cylinder, or any other possible device, can possibly afford complete and adequate protection, and that no ordinary protector can switch the whole of a flash out of a coil.

The handiest method of working with Leyden jar discharges is to use a couple of jars, to connect their internal coatings with the terminals of an electrical machine, the distance apart of whose terminals regulates the energy of the discharge employed, and to connect the outer coats of the jars to the two ends of the rod, or to the two rods of the universal discharger, or to whatever the flash is wanted to pass through. Instead of a wire tangle or loop, which only typifies the coil of an instrument, and whose only advantage is that one has no compunction in spoiling it, I employ an actual galvanometer, and take it as representing anything requiring protection. A galvanometer serves pretty well, because it indicates whether any disturbing current passes round it or not. It only indicates, however,

Digitized by Google

when the discharge really goes round the coil. If it jumps across insulation, and, still more, if it jumps from terminal to terminal, the needle indicates less or nothing. There are, in fact, two things to be aimed at and considered separately in the protection of instruments. First, the current has to be prevented from passing round the coil, and thus disturbing the magnetism of the needle; second, it has to be prevented from jumping across from layer to layer, and so damaging the insulation. The galvanometer I use is a simple reflecting instrument, of a pattern devised by Professor Stuart at Cambridge some time ago. I insert between the wires leading to the galvanometer a sort of lightning-guard—a pair of plates mounted parallel to each other on a sliding arrangement, so that their distance can be varied (Fig. 1). Directly the plates approach within sparking distance, the galvanometer is apparently protected, and its kicks cease, even though by extending the machine terminals further the energy of the discharges be increased. The non-deflection of the needle merely shows that no important quantity of electricity now finds its way round the coil. The galvanometer is by no means safe, for its insulation is in imminent danger, and if but moderately energetic flashes are employed we shall see sparks leaping across the coils or jumping from them to the metal work in a very pronounced manner. As this is rather rough on the galvanometer, I prefer not to use strong flashes, but to show the existence of the tendency with smaller ones by arranging a safety valve or supplementary minute air-gap between the galvanometer terminals; the safety valve being either a couple of pins brought close together (see Fig. 2), or a chink cut across a narrow strip of tinfoil pasted on glass.

An actual lightning-guard may, of course, be used, and its behaviour studied in detail. I take, as an excellent instance, a Saunders' protector, so much employed in connection with submarine cables. Its essential part is a fine wire, through which the useful currents have to pass, surrounded by an earth tube with points protruding towards the thin wire, which is stretched by a spring along its axis. The idea is that the tube will relieve the wire of dangerously high potential, while the wire itself will fuse if dangerously strong currents try to pass along it. A supplementary device is a short-circuiting contact, whereby a spring puts the cable to earth directly the wire is fused or in any other way broken. The diagram (Fig. 3) sufficiently represents the instrument. A Jamieson protector is a neat arrangement, involving a fine wire as well as an air-gap; there is also some wire coiled on a metal cylinder, but the metal deprives it of all appreciable self-induction. If I send very small discharges down the line wire towards a galvanometer protected by this Saunders' guard, they will, if small enough, escape it and pass through the galvanometer, either exciting its safety valve or disturbing its needle, or both. But if stronger flashes are sent, the protector begins to act, sparks are seen between the fine wire and the surrounding tube, and the galvanometer disturbances diminish; but those at the safety valve never wholly cease. One is not to suppose that the bigger the flash the less the effect; that would be a very desirable but somewhat impossible conjuncture. The smallest effect is got with the weakest flash which is just sufficient to spark to the protecting tube. Anything stronger or anything not greatly weaker than this gives larger effects. The fine-wire part of this guard is a good feature, and one that may be advantageously introduced into any protector, on the principle of a safety-fuse or cut-out, to eliminate steady or slowly varying currents of too great strength. But the short-circuiting of the protected terminal to earth by the terminal D as soon as the wire is destroyed, is perhaps not an unmixed good, for a subsequent earth-seeking disturbance has then two paths between which it may divide—if the connections are made as in Fig. 3—one along the intended earth wire, and the other through the instrument intended to be protected. We see how important it is to make the earth lead as short and direct as possible, and how it is better to connect the thing to be protected to the two binding screws C and D of the instrument as indicated by the dotted line rather than to make an independent earth.

I will now describe the principle of my own lightning-guard, and will then connect it to the circuit in place of Saunders', and show that it affords practically complete protection for both small and big flashes. The principle is to take the overflow from one protector and give it the chance of another, then to take the overflow from this and offer it another air-gap, and so on till nothing is left; at the same time diminishing the overflow from each protector as much as possible by the use of self-induction coils, which impede the violently varying or alternating rushes by their electromagnetic inertia. Thus, for instance, using a series of plate protectors, we may couple them up as shown in Fig. 4. Only a small fraction of a sudden shock will escape No. 1; say, a thousandth part, since it is offered the inertia or impedance of the coils as the only alternative. A thousandth of this again may escape No. 2; and a thousandth of this, or a thousand-millionth of the whole, is all that is left for the galvanometer. By adding to the series, if it were necessary, it is manifest that a disturbance may be diluted down to any desired extent, with the rapidity of a geometrical progression. I do not indeed propose to use plates commonly, but propose simple brass rods for the exposed air-gap, adjusted just far enough apart to exclude that disturbing thermo-electric or other effect caused by a spark occurring between their surfaces. The theoretically best place to tap off the useful current is from near the tips in contact, so as to tap off a minimum of impedance with a maximum. (See Fig. 5.) A, B are the exposed, or line and earth, terminals; C, D are the protected terminals.

Dr. Alex. Muirhead has kindly made me a highly-finished instrument on this plan, and I have also received from him a round and more compact form, illustrated in Figs. 15 and 16. My instrument is symmetrical—*i.e.*, there are just the same coils in its earth-connected as in its insulated portion. For alternating currents, at well as for rushes of uncertain direction, I think a symmetrical protector is best.

I insert in the so-called protected wire an arrangement of air-gaps and self-induction coils, after the fashion which constitutes my system of protection (Fig. 6). Then, inserting a fine wire, or a coil, or a galvanometer, or any other detector, in the interval, and connecting the far end of the wire to anything as before, it will be found that, although every trace of signalling current is able to affect the galvanometer, no appreciable trace of a violent disturbance is found there; it is now securely protected whichever way the disturbance comes. The electromagnetic inertia possessed by the coils cannot exert this protective influence alone, without successive air-gaps. The *combination* of air-gaps or escape valves along with obstructive inertia is essential to the device. The self-induction of my coils is quite small; a very small amount of wire thus distributed suffices. Three or four yards of No. 16 wire are all I need use.

The fact that cables are always coated with a stout metallic sheathing is a peculiar circumstance not found in the lines of land telegraphs, whether overhead or underground, and it is a circumstance which renders their complete protection from lightning peculiarly definite and easy. It is clear that risk is run, however, wherever a cable is connected to a land line. The land line to the station is often led to the same switch-board as the cable instruments are connected to; and whenever there is any sort of proximity of this kind a flash received by some distant part of the land line must be liable to spit across some of the terminals and flick off a bit of itself into the cable and its instruments. Two lightning switches, at least, ought to be employed in every such station: one, a coarse one, at the place where the land line enters the building, to eliminate the grosser violence; and another, a fine one, at the mouth of the cable, to filter out the last traces of dangerous disturbance. The mode of connecting one of my protectors to a cable is shown in Fig. 7. Here the outside sheath of the cable is used as sole earth. Another proper mode is to have a subsidiary or local earth, connection being made as in Fig. 8.

Its instruments can also be protected perfectly well by putting them all inside the sheath of the cable. The sheath would have to be enlarged; in fact, it might be made into an iron house, to contain the whole of the instruments and the operators. Reliance is commonly placed on the short-circuit of cable and sheath. If the short-circuit is very short indeed, the reliance is fairly justified; but if it be effected by a loop of any size (Fig. 9) then there is no absolute security, for a flash striking at A will bifurcate, and part of it rush into the cable. But if instead of a mere loop we put a thimble or hollow metal vessel over the end of the cable, connecting its sheathing to the walls, and connecting its core to the interior, then no sudden splashes can enter the cable at all; they will keep to the outside, and do no harm (Fig. 10). Such a magnified thimble is the proposed metallic or wire-netted cable station; and it is one that has the advantage of never needing to be removed—one which contains instruments and operators, and protects them all alike from dangerous disturbances (Fig. 11).

It may be asked whether a house thus made should depend for its earth entirely on the cable sheathing, or whether a local earth should be provided? It is not a vital point; but a local earth is to be recommended, in order that even the outer sheath of the cable shall not have to carry flashes of exceptional violence, which might unduly heat it. Again, gas pipes, water pipes, and everything else, may be permitted to enter the house, but only on the strict condition that they be effectively united to it at their point of entering, not at some other point. Since no insulated conductor must on this plan be allowed to penetrate the walls, it is manifest that no land line can be permitted to enter a cable station. The land signalling station must be a separate chamber. It need not be a distinct building; it may be under the same roof, but it must be wire-fenced off from the cable compartment, and the messages must be put through non-electrically.

It is customary to land the ends of cables in a cable hut on the beach, so as to be able to get testing instruments as close as possible to the real thing, undisturbed by insignificant shore leads. There is not the slightest difficulty or danger introduced by this practice, provided the hut or an enclosure inside it is made of iron, and both cable and shore-lead are well connected to its walls by their outer sheathing as they enter it. The cable hut need not be itself of iron; if it contains an iron box, as shown in Fig. 12, all requirements will be satisfied.

It is not to be supposed that any such cable houses afford any protection against earth currents, or any other steady or slowly varying effects. These will produce their full effect quite careless of the fact of metallic enclosure. Nothing but a *perfectly* conducting screen can entirely protect against them, and that is not a likely invention. Atmospheric disturbances also, and even discharges, *in so far as they are slow* or leave subsiding effects behind them, will be felt by the galvanometer; but then, although inconvenient to a reader of signals, slow disturbances are not dangerous. It is the violent and sudden rushes that are dangerous, and these are wholly excluded, occurring only in the outer metallic sheath. To exclude steady currents of too great strength a short length of very fine wire must be included in the circuit.

But now arises a very interesting question. The protection thus illustrated, is it theoretically perfect, or only perfect enough for all practical purposes? Does a metal cage protect a galvanometer absolutely from these sudden disturbances? Mr. Chattock and I obtained the following result a year or two ago, viz.: that between two wires wholly inside a wire-gauze house not a trace of spark can be obtained, whatever flashes pass along the outside. The only way we got sparks inside a metal enclosure was by allowing one of the wires to protrude a little through a hole in the walls without touching the sides of the hole. Thus, for instance, Fig. 13 gives no sparks inside, but Fig. 14 may give some very small ones.

But what about the conduction test? Insulation is safe enough, but will the signalling be interfered with during the continuance of a storm? If we try the experiment by putting a galvanometer inside a good conducting vessel and attaching its terminals to the walls—a small patch of gauze being, of course, provided for the ray of light to get in and out—nothing will be seen when ordinary flashes are given to the cage.

The protection of a galvanometer from these sudden discharges is not theoretically complete. No amount of covering-in can absolutely eliminate all disturbance. No matter how sudden a pulse may be, so long as there is an integral passage of electricity in one direction along a conductor, the central portions of that conductor will convey some trace of it. The integral passage of electricity along the axial wire is, in fact, that determined simply by its relative conductivity as compared with its surrounding sheath, irrespective of more complicated considerations. But whereas in the outermost layer of the sheath there are violent surgings, the current-strength being very great and alternating, nothing of the sort occurs in the central portions; the violence is all damped out, and there remains nothing there but a quiet and sluggish flow. The rush in the outer layer of a conductor induces currents in the layer next below, these again in the layer below that, and so on.

In the discussion which followed, Mr. Saunders said he got the idea of his lightning guard in 1864 from noticing that cables were generally connected to land lines through a fine wire enclosed in a glass tube. These wires were frequently fused and the tubes broken, so he replaced the glass tube by a brass one connected to earth. After this fusions were less frequent. In his practical experience of twenty-five years, he had never known a cable or instrument protected by his guard to be damaged, although the wires have been often fused. During a very sudden and violent storm on February 14th, 1888, the wire was fused, but nothing else damaged. Their length was 15in., diameter ·0027in., and resistance 45 ohms. These, Mr. Saunders said, were frequently fused. In his opinion Dr. Lodge over-estimated the chances of damage. Injuries due to lightning were of rare occurrence. As regards Dr. Lodge's guard, Mr. Saunders thought it very ingenious, but before it could be pronounced successful it must stand the test of practical use.

Sir W. Thomson thought a condenser with Saunders' fuse wire would be an efficient protection for cables, for the quantity of electricity required to make the difference of potentials between the plates considerable would probably be more than sufficient to fuse the wire. A sufficient length of fine wire would prove an efficient protection. He did not wish to express any adverse opinion on Dr. Lodge's guard, for he would like to see it tested in practice; at first, however, he would also insert a Saunders' protector between it and the cable as an extra precaution.

Mr. Preece said that it was quite unnecessary to assume that lightning flashes were oscillatory in order to understand that self-induction may be beneficial in causing a discharge to jump over a spark gap, for all admit the suddenness of the flashes, and this was the only essential point. Out of 600 valuable instruments not a single one had suffered damage from lightning in 1889. Only one case of damage had occurred to cables since 1879, and in this considerable doubt existed as to whether the injury was caused by lightning or not. From these facts he concluded that no want for a new protector exists, and that none can give greater efficiency. As regards economy, he said the ordinary protectors cost from 2s. 9d. to 3s. 6d., whilst those for cables were about £1.

Mr. Charles Bright directed attention to Sir Charles Bright's guard, and said it was particularly useful in cable huts, for if one wire was fused the remaining ones were available.

Captain Stiffe said that on the Persian Gulf cable he had used a protector, consisting of a Siemens plate guard and a fine platinum wire. Sometimes the wire was melted and the plates had been fused together, but no damage resulted to the instruments or cable.

Sir Henry Mance corroborated Captain Stiffe's statements, and said that since the Persian Gulf cable came under his charge he had modified the guard by winding the fine wire into a spiral and enclosing it in a glass tube to prevent mechanical injury. He admitted that obscure faults do sometimes occur, but did not think they were due to lightning.

Major Cardew thought Dr. Lodge's apparatus was not necessary for ordinary lines. If, as Dr. Lodge supposed, the line was struck outside the station, then, even at a comparatively short distance away, the impedance of the line would exceed that of Dr. Lodge's coils, and a kind of spark gap exists at each insulator.

Professor Hughes considered the communication under discussion very important, inasmuch as it recognised the value of impedance in lightning protectors. Many of the older protectors contained analogous arrangements, but their inventors failed to see their importance.

General Webber said that from his own observations on storms in Eastern countries, he was inclined to think that protection was due to the points of release at every insulator more than to anything else. As regards electric light circuits, he inquired whether bare or covered underground conductors were most likely to be damaged by lightning. Some time ago, in his own house, which was then lighted by 25-volt lamps, he noticed, or thought he noticed, the lamps go dark immediately after a vivid lightning flash, and again regain incandescence.

Professor Ayrton pointed out that the lightning protectors of Mr. Preece and Mr. Saunders could not be applied to electric light circuits, for it was admitted that plate protectors were insufficient, and the fine wire was inadmissible. He said he had known polarised relays to be frequently reversed by lightning. In one instance he saw a flash strike a line about a quarter of a mile from the station; every insulator between the point struck and the station was smashed, the relays fused, and all the instruments damaged.

Mr. Mordey said that it was not so much the lightning that is to be feared in electric light circuits as the current from the dynamo following the path of the discharge and forming an arc. Means must be devised for breaking up such arcs, and it was more in this direction that electric light engineers were working.

Digitized by Google

Mr. Spagnoletti recalled an instance of lightning striking an aërial line, and completely demolishing all the insulators and arms on ten poles, as well as splitting the poles themselves into fragments. These and other cases seemed to show that the protection afforded at the poles referred to by Major Cardew and General Webber was quite insufficient.

Mr. Crompton made inquiries as to how electric light circuits were to be protected, and wished to know if it was necessary to put protectors into each house, or whether protectors at both ends of the leads would be sufficient.

Dr. Lodge said that, judging from the statements of several of the speakers, the ordinary protectors did their work well, but they were all open to the objection that they were frequently damaged. Whenever protectors were damaged he contended that something else had also been damaged, although the injury might not be visible. He could hardly accept the statements made by the men of experience who said that they never came across faults that could not be accounted for, and he maintained that any unexplained fault *may* be due to lightning. As regards the advantages of fine wire, he said its use was essential to safety. In his paper he had pointed out that two things had to be guarded against —viz., high potentials and strong currents. His apparatus reduced the high potential, and fine wire was a protection against strong currents. As pointed out by Sir W. Thomson, the fine wire should be at the protected terminals. In reply to Mr. Preece's statement that the self-induction of instruments was sufficient to cause the spark to jump across air spaces, he said that if the coils were wound on iron cores or metal reels their self-induction for flashes was negligeable, and in any case lightning would take no notice of silk or cotton insulation. Moreover, the shapes of the coils used were by no means such as would give maximum self-induction. He thought Sir W. Thomson's suggestion of a fine wire and a condenser a valuable one. If underground wires were entirely underground they would be more secure. In answer to Mr. Crompton's inquiries, Dr. Lodge thought the same principle as is used in protecting buildings from fire by means of fire-proof doors should be adopted, and protectors should be placed wherever underground wires leave the earth.

NOTES ON ALLOYS.

V.

At a meeting of the Society of Arts, held on Tuesday evening last, Professor W. C. Roberts-Austen gave a lecture on the "Art Metal Work of the Japanese, and the Alloys used by them." The lecturer has, for some years, made a special study of the constitution of these mysterious and remarkable alloys, and he has succeeded in reproducing all the colours and effects which are characteristic of Japanese art metal work. From the exhaustive analyses which he has made of a great variety of ornaments, plaques, &c., it appears that there are four chief alloys whose names and constitutions are given as follow:—

SHAKU-DO.

Copper	94·50
Silver	1·55
Gold	3·73
Lead	·11
Iron and arsenic	traces
	99·89

SHIBU-ISHI.

Copper	67·31
Silver	32·07
Lead	·52
Gold	traces
	99·90

KUROMI.

Copper	98·04
Antimony	1·96

BRONZE.

Copper	76·9 — 87
Tin	23·1 — 13

There is also a fifth alloy, viz., Japanese brass, which occurs in the various ornaments, but its constitution has not yet been published. The most striking feature of these alloys is that the precious metals take the place of tin and zinc in English alloys. Shaku-do is generally of a dark purple colour, but the slightest variation in the percentage of the gold in it makes a great difference in the colour. The class of alloys called Shibu-ishi are all of grey colour, and are both light and dark. Kuromi is mostly copper, and has from ·2 to 2 per cent. of an admixture of other metal, such as bismuth, nickel, iron, arsenic, and gold, and the colours vary between wide limits, from brown and red to purple-black. The colours of each alloy may be varied by the production of coats of oxides or salts of the metals. This is done chiefly by pickling solutions, by heat, and by atmospheric exposure. It has also been suggested that some of the effects may be obtained by exposing the surfaces to the action of certain fumes. It is hardly necessary here to go into the details of the artistic effects produced by the judicious blending of these alloys, or to discuss the fitness of embodying both colour and texture in a work of art; neither will our space allow of our quoting examples of the extraordinary beauty of some of the Japanese inlaid designs. Suffice it to say, that at the South Kensington Museum there is an admirable collection of specimens of this art.

There is also an alloy used largely by the Japanese, called Moku-me, resembling marble in its texture. It is formed by taking sheets of the above-named alloys and laying them one upon each other, and then twisting folding, punching, and welding them in all manner of ways. When the surface of such a mass is polished it presents the appearance of marble, with the different coloured streaks winding about like a maze. The effects produced by these operations are extremely delicate and beautiful. Though no Western artists have successfully reproduced any of the inlaid work of the Japanese, yet Christophele, of Paris, and Tiffany, of New York, have executed some admirable work in Moku-me. At the late Paris Exhibition a vase 29in. high was shown by Tiffany, and the price put upon it was £1,000. Messrs. Elkington have also been successful in manufacturing articles in this manner, but as they could buy them from Japan at a twentieth of the price at which they made them, they hardly felt encouraged to proceed.

Little is known concerning the constitution or properties of the alloys containing three metals, as hitherto investigators have chiefly directed their attention to a study of the binary alloys. Dr. C. R. A. Wright and Mr Thompson have, however, in a recent paper communicated to the Royal Society, laid the foundation for future work on those complicated alloys which contain three metals. They chose as their first combination the metals tin, lead, and zinc, which were melted together and left at rest in a fused condition. When the percentage of tin exceeds a certain amount the mixture remains homogeneous, but when the amount is less than this the mixture separates into two layers, each layer containing the three metals. This limiting quantity of tin in the authors' experiments, which were conducted at a temperature of 600°–700° C., was found to be three-eighths of the total weight of the three metals. The heavier of the two layers which separate when the quantity of tin is lower than this consists of a saturated solution of zinc in lead containing tin, while the upper layer is a saturated solution of lead in zinc containing tin. The tin does not distribute itself equally in the two alloys, except when present in a particular proportion, which varies with the ratio of zinc to lead. With less tin than this, the lighter alloy takes up the excess of tin, and when the amount of tin is in excess of this amount, the lower alloy contains all this excess. They have, therefore, succeeded in obtaining a series of alloys in this way in which separation takes place on cooling, the lower alloy always having the same composition while the lighter one varies in composition, and a second series in which the upper alloy is uniform in composition and the heavier one varies with the amount of tin added. When no tin is added, they further find that lead is capable of dissolving zinc, forming an alloy containing 1·24 per cent. of zinc, and also that zinc dissolves lead to the extent of 1·14 per cent. In the Parkes process for the desilverising of lead by means of zinc a similar kind of separation takes place, which may be compared with this work of Dr. Wright and Mr. Thompson on the ternary alloys, and it will be in the recollection of our readers that it has recently been shown that there is a similar selective action when the attempt is made to form a ternary alloy containing lead and aluminium with a third metal (see *Industries*, Vol. VIII., page 236). A peculiar crystalline alloy, containing lead, tin, and copper, has recently been examined by Mr. A. French. It was found in a cavity at the bottom of a cupola furnace after being used for lead smelting. On analysis, however, it was found to contain, in addition to these three metals, nearly 4 per cent. of antimony, and traces of iron, silicon, and sulphur, and can, therefore, scarcely be regarded as a simple ternary alloy.

THE SOCIETY OF CHEMICAL INDUSTRY.

MANCHESTER SECTION.

On the 6th inst. Dr. Liebmann read a paper on "Pure Aniline and its Homologues." The commercial value of an aniline was based on determinations of the solubility, boiling point, and specific gravity of the liquid. As the literature on the subject gave different figures for the above, he had prepared pure specimens and carefully determined these constants, with the following results :—

Aniline, sp. gr. 1·007, boils 182° C.
Ortho-toluidine, sp. gr. 1·0037, boils 197° C.
Para-toluidine, melts 45° C., boils 198° C.

Sometimes sulphur compounds occurred as impurity in aniline, though, since the publication of Professor Victor Meyer's researches on thiophene, the quality of commercial benzenes had much improved. The best test for para-toluidine was the melting point, which was much lowered if any quantity of the ortho compound was present.

Mr. Carter Bell then read a paper on "The Liability of Certain Oils to Spontaneous Combustion," in which he pointed out that the determination of the heat produced by the reaction of chloride of sulphur on the oils was an important factor to determine, as he had found that the greater the rise the more liable was the oil to spontaneous combustion. By placing the oil in a flask containing oxygen connected with a water gauge, the amount of oxygen absorbed could be seen by the rise of water in the gauge —the most dangerous oils absorbed oxygen the quickest. The most reliable test consisted in putting a certain weight of wool saturated with the oil in a water-jacketed vessel open at both ends, having a thermometer in the water and in the wool; heat was then applied, and the temperature when the wool began to smoulder was noted. He gave the results of a large number of tests made with various wools and oils, some of the figures being widely different. A series of experiments were also made under conditions similar to those occurring in woollen mills, a larger quantity of wool—about 6lb.—being taken for the tests. Mr. Bell said it was the general opinion among manufacturers that white wools, when greased, were more liable to spontaneous combustion than dyed wools. He, however, had found exactly the reverse, by a series of tests which he had made to specially determine this point. In his experiments the wool had always smouldered away without actually bursting into flame; and in fact, with regard to flame, from inquiries which he had made, he did not think that such a thing as an outburst of flame ever occurred in mills. It was most important that all woollen mills should be kept thoroughly swept and clean.

In a short discussion which followed, Dr. Bailey, referring to the influence of mass upon experiment, suggested that tests should be made in which a large quantity and a small quantity of wool should be taken, and a Grinnell sprinkler imbedded in each, so as to see which produced the greatest heat first. With regard to the influence of water in the wool this would cause a reduction of temperature, owing to the loss of heat due to its conversion into steam. Mr. Thomson objected to the manner in which the tests were carried out, and thought that the results obtained were not of much scientific value, especially as the oils occurring in commerce were very rarely pure. Mr. Hurst said he had experimented on this subject, but had not obtained any satisfactory results. He regretted that Mr. Bell had not experimented with mineral oils, as these were now being much used in cloth manufacture. Mr. Bell, in reply, said that his figures were not put forward as scientifically accurate, but were intended to be of interest to millowners, as showing the difference between the various wools and oils with regard to liability to spontaneous combustion.

Notes.

BRIN'S OXYGEN PRÓCESS FOR GAS PURIFICATION.

The process of gas purification by means of oxygen gas, which was first attempted on a commercial scale at Ramsgate, and of which we gave a full description some time ago (see *Industries*, Vol. VII., page 574), has been adopted at Shrewsbury with success, and we understand that the Rochdale Town Council and the Montreal (Canada) Gas Company have also decided to adopt this system, and have given orders to Brin's Oxygen Company for the erection of the necessary plant.

THE ORDNANCE SURVEY.

From a Blue Book which has just been issued, we learn that, in connection with the Ordnance Survey, plans of twenty-three towns were published during the past year, and that these complete the plans of all the towns in England and Wales, all of which have now been published in accordance with the various Treasury minutes on the subject. All the counties have been published on the 6in. scale, with the exception of Devon, Salop, and Wilts; and the map of England and Wales, on a scale of four miles to an inch, is in the hands of the engravers, and the outline edition is in a forward state. The total expenditure on the Survey has been £1,697,678, and it is expected that £200,000 more will be required to complete it.

A MINIATURE STEAMSHIP.

A magnificent ship model, representing one of the three swift and powerful mail steamers now being built at Barrow for the Canadian Pacific Royal Mail Company, has just been completed by Messrs. Kelso & Co., model makers, of Glasgow, who have a high reputation in this line of business. The model is fully rigged, and is enclosed in a handsome glass case. It represents, on a scale of ¼in. per foot, a twin screw vessel, having a graceful clipper stem, lines exhibiting much fineness of entrance and run, and with a full sharp-bilged midship body—altogether a likely craft to attain the speed of 19 knots, for which she has been designed, and prove a comfortable sea boat. The full-size dimensions are—485ft. length, 51ft. beam, and 36ft. moulded depth, the tonnage being 5,700 gross. The engines will indicate 10,000 horse-power; and, as Mr. Bryce-Douglas now holds the reins in the Barrow establishment, it may safely be predicted that the required speed will be attained The destined station for the vessels is between Vancouver and Japan and China, and, to judge from the large number of lifeboats provided, the accommodation for passengers will be most extensive. The model shows the vessels to be armed with guns of the most approved type and calibre, for service as a reserve cruiser of H.M. Navy. The faithfulness with which the model makers have reproduced in miniature every item of deck fitting, masts, and rigging, down even to individual rivet heads and links of chain, reflects great credit on Messrs. Kelso & Co. The model, we understand, is to the order of the Barrow Shipbuilding Company, but is intended for the offices of the owners.

THE RESULTS OF THE "CHALLENGER" EXPEDITION.

Many developments of industry and commerce have been the results of investigations which have seemed to have no practical application. The work which has been done in connection with the "Challenger" expedition is, of course, of great interest to the pure scientist, but sooner or later it will be discovered to be of immense practical value. The reports which have been published in connection with it form a library of forty-seven quarto volumes, with nearly twenty-eight thousand pages of letter-press, more than two thousand five hundred lithographic and chromo-lithographic plates, four hundred maps, charts, and diagrams, together with a great many woodcuts. The preparation and publication of the reports have cost no less than £88,000, and the amount recovered by sales does not yet reach £18,000. The part of the report which is most interesting to us is that which gives information about harbours, tides, currents, and prevailing winds of out-of-the-way spots, which will be of use to those engaged in maritime and commercial pursuits.

A NEW QUARTERLY REVIEW.

The latest novelty in journalism is a quarterly review of current topics, entitled *Subjects of the Day*. It is "special" in a different sense from the ordinary journals, for instead of being devoted to a certain department of literature, science, art, or politics, each issue is to be entirely taken up with the discussion of a subject which is attracting attention, and will form a volume in itself. The first subject taken up is that of "State Education for the People." The articles are not by any means of a technical nature. The first is by Sir W. W. Hunter, President of the Indian Education Commission, and gives a most interesting account of the results of State education in India. Then follow accounts of the systems of education in England, Scotland, and Ireland, and a comparison of British and Continental and American systems. There is an article on "The Education and Status of Women.' Sir Philip Magnus dwells on the evils of payment on results in technical education. The new Codes which have been drawn out for the present year in the department of elementary education have practically abolished this system, and it is to be hoped that the subject will now be taken up in connection with the grants given by the Science and Art Department, where the effects are even worse than in elementary schools.

ECONOMIES IN STATE PRINTING.

We sometimes flatter ourselves on our generosity when a comparatively small sum is voted for purposes connected with education, science, or art, but we seldom or ever consider how much money is at present absolutely wasted. Attention, no doubt, is being directed to this matter in several departments, but as yet only a beginning has been made. In the Stationery Office, for instance, Mr. Pigot, the director, declares that he is well within the mark in saying that—going back at furthest to the year 1875 for a comparison of prices—the cost of a first-class battleship, complete in all its armaments, with an attendant flotilla of half-a-dozen gunboats, has during the last ten years been saved, without inconvenience to the public, on Government printing and stationery. This has been done mainly by cutting down the printing rates, and by reducing the number of copies of Parliamentary papers supplied to members. Instead of sending to each member a copy of every printed paper, only those are supplied which are asked for, a step which might have occurred to those in charge long before this, as few members have either time or inclination to read all the Parliamentary papers. Then, again, increased facilities have been given to the public for the purchase of papers, and the prices have been very much reduced compared with what they were a few years ago. No returns have yet been published showing how far the public has taken advantage of these opportunities, but we would imagine that in these days of political activity that many will avail themselves of them.

Patent Record.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

28th April, 1890.

6413. Junge, W. ..... Saws.
6415. Holding & Holding ... Looms.
6417. Lees, T. W. ..... Lubricating apparatus.
6422. Jones & Jones..... Cigar-making machines.
6424. Tschoepe, C. ..... Mechanical stoker.
6432. Stones & Stones ..... Lock nut.
6442. Pett, F. S. ..... Ship's logs and sounding apparatus.
6444. Darne, R. ..... Firearms.
6445. Smith, J. ..... Tension pulleys of spinning machines.
6452. Moore, A. W. M. ..... Wheels for road vehicles.
6453. Ramsey, H. E. ..... Circular boilers, &c.
6454. Penk & Krenner ..... Numbering presses.
6461. Pielsticker, C. M. ..... Metal sheets.
6469. Jones, C. ..... Street-watering apparatus.
6470. Horn, W. W. ..... Steam pumps (*Beatty*).
6472. Ainley & Oakes ..... Machinery for cutting square holes.
6474. Parratt, G. F. ..... Life rafts.
6477. Wells, C. ..... Steam engines.
6484. Fletcher, G. ..... Evaporating pans.
6485. Mellstrom & Bremberg Ordnance.
6487. English, T. ..... Raising gun platforms.
6488. English, T. ..... Carriages for quick-firing guns.
6489. Imray, O. ..... Low water alarm for steam boilers (*Wildman*).
6491. Reed, Sir E. J. ..... Connecting railways separated by rivers by submerged tubes.
6494. Carey, W. ..... Pipe couplings.
6498. Hoskins & Hoskins ..... Punching machine.
6499. Hoskins & Hoskins ..... Machine for caulking joints.
6500. Thompson, W. P. .. .. Feed-water heaters (*Stub*).
6502. Lake, H. H. ..... Burning hydrocarbon oil as fuel (*Sieft*).

29th April, 1890.

6508. Kelly & Dougherty ... Ordnance.
6509. Weston, G. H. ..... Rotary engines.
6510. Woodward, R. G. ..... Sewing machines.
6511. Musgrave, W. M. ..... Pistons.
6512. Brown, G. ..... Spinning machinery.
6513. Johnson, J. Y. ..... Friction catches (*Lewis*).
6514. Cook, W. ..... Multitubular boiler flues.
6523. Parker, J. ..... Barrel setting-up machines.
6525. Elliott, W. ..... Stitching machinery.
6526. Hammerton, C. ..... Tool holder.
6529. Bramwell, J. H. ..... Hardening steel.
6536. Fox & Williamson ..... Reversing valves for gas furnaces.
6541. Paley, G. ..... Sewing machines.
6552. Gimlinton, F. H. ..... Projectiles.
6557. Oertel, E. O. ..... Recording working of engines.
6558. Schott, A. J. ..... Sea calming apparatus.
6559. Lunkenheimer, E. ..... Straight way valves.
6562. Aiken, H. ..... Railway axles.
6571. Gobiet & Carrer ..... Corrugated metallic tubes.
6573. Jackson, J. ..... Pressure gauges.
6578. Thompson, W. P. ..... Construction of buildings (*Smead*).
6579. Thompson, W. P. ..... Desiccating apparatus (*Smead*).
6585. Lake, H. H. ..... Automatic guns (*Maxim*).
6588. Fombuena, V. S. ..... Cigarette machine.
6590. Churchill, J. D. ..... Governing steam engines.
6591. Lake, H. H. ..... Automatic guns (*Maxim*).
6593. Williamson, F. ..... Lubricators.

30th April, 1890.

6597. Terry, H. K. ..... Purification of middlings (*Pope*).
6600. Evans, W. L. ..... Weighing machine.
6602. Wild, J. ..... Joints for flexible hose.
6603. Thorp (of the Firm of J. & J. Hayes, Ld.) & Allen ..... Yarn guide traverse motions.
6617. Binns, J. P. ..... Gas engines.
6621. Brown, A. B. ..... Marine engines.
6622. Ross, Sir C. H. A. F. L.... Governing motors.
6625. Murrie, J. ..... Feed-water regulator.
6632. Ménard, R. ..... Gas engines.
6635. Thompson, W. P. ..... Valve rod packings (*Touceg*).
6641. Gillings, J. ..... Railway chair bolts.
6643. Gersant, J. ..... Ordnance.
6645. Lancaster & Couley ... Iron and steel.
6647. Hawks, N. S. ..... Furnaces.
6650. Leigh, H. H. ..... Multiple saw frames (*Jeansaume*).
6654. Davey, C. J. ..... Automatic brake.
6657. Bayly, J. P. ..... Locomotive (*Goulding*).
6660. Brophy, M. M. (of the Firm of James Slater & Co.) ..... Furnaces.
6661 Brophy, M. M. (of the Firm of James Slater & Co.) ..... Gas heated ovens.
6663. Taunton, R. A. P. ..... Spring gun.
6668. Vigers, E. ..... Tubulous boiler.
6669. Greenwood, H. ..... Machinery for shaping teeth of wheels.
6672. Lake, H. H. ..... Tool steel bars (*Garnier & Weil*).
6674. Kent, W. G. ..... Liquid meters.
6676. Shearer & McCutcheon Land grubbers.

1st May, 1890.

6677. Jerrard, E. P. ..... Multiplying hydraulic power.
6680. Taylor, P. ..... Bottle corking machines.
6684. Richardson, W. H. ..... Carding engines.
6686. Ashworth, Ashworth, & Ashworth ..... Driving gear of textile machinery.
6688. Partington, E. ..... Paper-making machines.
6692. Thornley, T. ..... Furnaces.
6694. Edwards, Davies, & Williams..... Casting ingots, &c.
6697. Birtwistle, W. ..... Loose reed looms.
6699. Simpson, H. J. ..... Ship's boat disengaging gear.
6702. Kay & Young..... Machinery for shearing pile fabrics.
6703. Jeffrey & Cockburn ... Stop valves.
6708. Hare, W. L. ..... Rollers for printing fabrics.
6709. Gehrling & Durran ... Eyeletting machines.
6718. Ashlin, H. C. ..... Furnaces.
6720. Clarke, G. T. F. ..... Implement for setting saws.
6722. Kirkby, J. ..... Drying kiln.
6725. Morris, R. ..... Projectiles.
6731. Collette, F. ..... Apparatus for preventing explosions in mines.
6732. Marsden, G. ..... Machinery for making hearth-rugs.
6736. Edwards, E. ..... Stop valve (*Adam*).

2nd May, 1890.

6745. Gatenby, H. E. ..... Spinning machinery.
6749. Cochrane, W. ..... Automatic shunter.
6750. Farran & Crawford ... Looms.
6759. Barnes, S. ..... Printing machines.
6761. Newton, J. E. ..... Hydraulic motors.
6764. Wilkinson, N. ..... Railway waggon or carriage.
6770. Scott, R. ..... Lace machinery.
6772. Morier, A. H. ..... Roaching machines.
6777. Crowley & Douglas ... Railway signalling.
6792. Simon, H. ..... Apparatus for cleansing wheat.
6794. Ohl, E. ..... Stretching machines.
6799. Human, E. ..... Flexible couplings for shafts.
6810. Smith, A. P. ..... Apparatus for tapping mains.
6813. Guy, C. W. ..... Crushing mills.
6815. Zimer, F. W. ..... Propelling boats.
6820. Lang, J. ..... Small arms.
6822. Penligen, W. H. ..... Ships' davits.

3rd May, 1890.

6827. Elliott, G. W. ..... Wheels and pulleys.
6828. Capone, F. ..... Aërial navigation.
6829. Adey, F. A. ..... Locating sunken ships.
6837. Bosshardt, F. ..... Drying and cleaning grain (*Perhees & Ferhaert*).
6839. Hoyer, F. ..... Metal for shipbuilding plates.
6840. Rigby, T. A. ..... Apparatus for purifying meal.
6842. Shabratt, A. ..... Furnaces.
6846. Dickinson, A. ..... Brake for tramcars.
6851. Southby & Blyth..... Refrigerating apparatus, &c.
6853. Poupard & Lewis..... Weighing machines.
6859. Carr, C. E. ..... Railway points and signals.
6865. Hartmann, E. ..... Pumps.
6870. Keefer, W. B. ..... Weaving carpets.
6872. Melhuish, A. G. ..... Gas motors.
6876. Ashworth & Kneen..... Furnaces.
6880. Hellinger, M. ..... Construction of walls.
6882. Coleman & Morton ..... Machines for road sweeping.
6885. Bayly, J. P. ..... Shaft coupling (*Capron*).
6894. Low, R. ..... Rolled forgings.
6896. Ambler, W. ..... Moulding cylindrical articles.

ELECTRICITY.

28th April, 1890.

6475. Lowrie & Hall ..... Safety device.
6476. Eagar & Milburn ..... Electrical batteries.
6490. Schweizer, E. ..... Electrical clockwork.
6492. Dewey, M. W. ..... Electric railways. (2nd November, 1889.)
6493. Dewey, M. W. ..... Electric refrigeration. (15th November, 1889.)
6495. Clark, A. M. ..... Telegraphs (*Shuckert & Co.*).

29th April, 1890.

6524. Ryland, W. ..... Electrical deposition.
6568-9. Lake, H. H. ..... Electrical measuring instruments (*Garver*).
6570. Dewey, M. W. ..... Electric refrigerating apparatus for railway vehicles.
6581. Lake, H. H. ..... Incandescence electric lamps (*La Société L'Incandescence Electrique*).

30th April, 1890.

6623. Warden & Smith ..... Switches for lamps.
6667. Frager, A. ..... Electric meter.

1st May, 1890.

6726. Von Hefner-Alteneck, F. ..... Electrical timepiece.

2nd May, 1890.

6793. Siemens Brothers & Co., Ld. ..... Combined electromagnetic coupling and brake apparatus (*Siemens & Halske*).
6795. Edmunds, H. ..... Storage batteries.
6801. Holmes, A. B. ..... Testing leakage and insulation of electrical conductors.
6811. Vogel & Calkins ..... Telephones.

3rd May, 1890.

6841. Smythe & Payne ..... Electrical fittings.
6878. Schmitz, R. ..... Electric alarm device for clocks
6893. Van der Poppenburg, J. Galvanic batteries.

CHEMISTRY.

28th April, 1890.

6416. Davis & Davis ..... Chlorine.
6433. Davis & Davis ..... Chemical furnace.
6462. Napier & Carr ..... Metallic alloys.
6463. Neave, E. ..... Oxygen from air.
6465–6. Pielsticker, C. M. ... Distillation of hydrocarbon oils.
6486. Imray, J. ..... Colouring matters (*La Société Anonymes des Matières Colorantes et Produits Chimiques de St. Denis*).

29th April, 1890.

6549. Plummer, J., Jun. ..... Hydrochloric acid and ammonia.
6553. Longsdon, A. ..... Oxygen from air (*Salomon*).
6575. Stringfellow, J. H. W. Manufacture of gas.
6584. Shedlock & Denny ..... Gas producers.
6587. Whiteman, W. T. ..... Distillation of alcohols (*Haeck*).

30th April, 1890.

6670. Cowper-Coles, S. O. ... Deposition of alloys.

1st May, 1890.

6698. Davis & Davis ..... Chlorine.
6729. Dreyfus, C. ..... Colouring matters.

2nd May, 1890.

6758. McEwen, J. ..... Generating carbonic acid.
6804. Andrews, W. C. ..... Purification of illuminating gas.
6821. Vivian, Sir H. H. ..... Copper.

3rd May, 1890.

6831. Davis & Davis..... Chlorine.
6834. Taylor, J. ..... Recovery of glycerine and salt from soapmakers' leys.
6850. Parry & Foskett ..... White pigment.
6864. Shedlock & Meldrum... Production of gases.
6874-5. Johnson, J. Y. ..... Colouring matters (*Badische Anilin & Soda Fabrik*).
6879. Lake, H. H. ..... Colouring matters (*Leonhardt & Co.*).

MISCELLANEOUS.

28th April, 1890.

6434. Wood & Bracewell ... Ventilating and moistening weaving sheds.
6439. White, C. H., Jun. ..... Wire-rope fencing.
6478. Efrem, J. ..... Dissolving boiler scale.
6497. Thompson, W. P. ..... Regenerative gas lamps (*Bucklin*).
6504. Wilby, J. H. ..... Driving belts.

29th April, 1890.

6517. Lóvold, J. M. ..... Distributing oil over waves.
6518. Lawrie, R. W. ..... Manufacture of tin boxes.
6555. Brewer, G. ..... Insulating composition (*Firth*).

30th April, 1890.

6612. Webb, R. T. ..... Bleaching yarns.
6644. Johnston & Johnston... Paper making.

1st May, 1890.

6706. Kimmins & Craig .... Separation of fatty matters from wool.
6711. Goodall, F. C. ..... Marine cement.
6715. Malmström, K. K. ..... Percussion fuses.
6730. Dreyfus, C. ..... Coloured rubber goods.

2nd May, 1890.

6819. Calmon, A. ..... Hose pipes.

3rd May, 1890.

6855. Higham, G. ..... Portland cement.
6867. Levita, C. B. ..... Percussion fuse.
6868. Turner, H. C. ..... Asbestos fuel.
6877. Hiertz & Garnett ..... Combustible coal brick.

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given, give notice at the Patent Office, in the prescribed form of such opposition.

Year 1889.

1676. Bamber.
7233. Thorp & Marsh.
7245. Hollinshead & Griffiths.
7429. De Haer & De Haer.
7627. Chalmers.
7185. Boult (*Page, Bird, & Bird*).
7256. Bour.
7287. Forrest & Sym.
7625. Rawson.
7747. Greene.

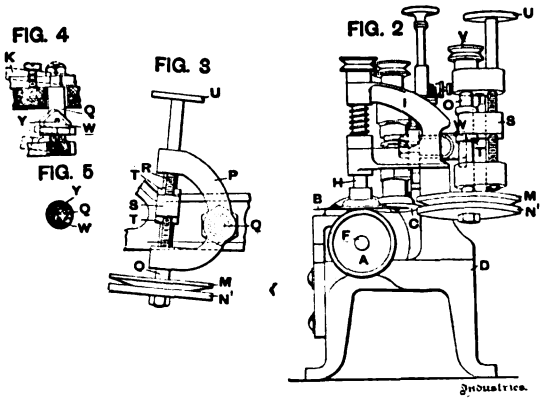
ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

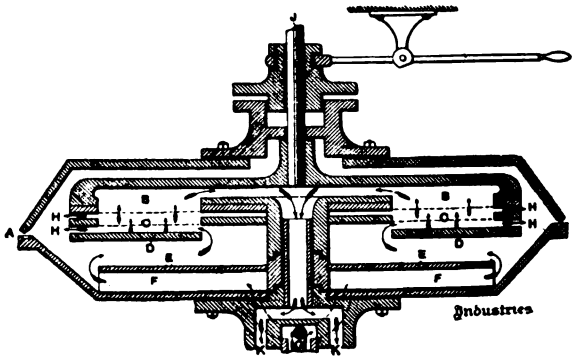


ENGINEERING.

Combined Treadle and Hand Driving Mechanism.—*F. W. Zimer, London.*—Improved means are here described for imparting a rotary motion to the wheels of bicycles, &c. The special object of the invention is to utilise the power of the bicyclist's arms as well as legs. The handle bar of the bicycle is made of the bent form, and so that it can be rotated at its point of attachment by lifting the handles. Below the handle and with one end pivoted to the bicycle frame is a lever. The other end of this lever is connected by a rod to a clutch upon the treadle shaft, whilst the centre part is coupled by a link to a loop secured to the handle bars. By lifting the handles the lever below it is raised, and the rod in connection with the clutch rotates the treadle shaft. The manner of coupling the lever to the handle bar above it is such as to permit the fork frame to be rotated in its bearings for the purpose of steering. This is effected by securing to the centre part of the handle bar a looped rod, part of which is concentric to the axis of the fork frame. The coupling link slides upon this loop, and so is not displaced by turning the frame. The gear may be used for other purposes such as propelling boats, &c. Five claims are made.—No. 7427A. May 3rd, 1889. 8*d*.

Leather-skiving Machines.—*C. E. Lewis, Boston, U.S.A.*—Means are here described for grinding the rotary skiving knives of these machines. The illustrations are:—Fig. 1, a side elevation; Fig. 2, a plan; and Figs. 3, 4, and 5, details of the improved

machine. The parts of the machine, such as the feed roll A, the feed disc B, and the revolving cutter C, are of the usual construction. The grinding mechanism consists of two abrasive discs M N¹, one of which has a feathered or chamfered edge, to present an annular groove or race for the cutter C. The discs are secured to a shaft O, having bearings in a frame P. The frame P is fast to a bolt or rod Q, to which the frame carrying the cutter C is also secured. The rod Q passes through a suitable bearing in the frame of the machine, and can be clamped in any position. By this construction it will be seen that the grinding disc or discs and the knife are simultaneously adjustable. As it is desirable to have the grinding discs act sometimes upon one and sometimes upon the other side of the cutter C, it is made vertically adjustable as shown. The means shown for accom-



plishing such vertical adjustment consists of a screw R turning in the bracket P. The screw passes through a block S, which embraces the shaft O, so that by turning the screw R the block S will be raised and lowered. The shaft O is revolved by the pulley V. Seven claims are made.—No. 14,439. September 13th, 1889. 8*d*.

Blast Furnace Blocks and Tuyeres.—*J. McCann, Millom, Cumberland.*—The object of this invention is to prolong the operation of the blast in furnaces by a different construction of the blocks and tuyeres. The blocks and tuyeres are constructed so that the greatest flow of water passes round the belly part nearest to the furnace, that being the part subjected to the greatest heat. The tuyere is made in two or more parts. The first part consists of a number of coils of tubing passing round the belly pipe, and the second part of another coil of tubing arranged immediately over that portion of the first nearest to the furnace. The coils of both block and tuyere, in their separate parts, may be arranged to run side by side round the belly pipe until the last coil of the first pipe is reached, when the second part may be raised to overlap the remaining coils of the first. The two or more sets of coils of tubing in both blocks and tuyeres have separate connections with the water supply for cooling them, so that they work independently. Thus, when one set is injured by the heat, the others will continue to keep the belly pipe cool. Five claims are made.—No. 7443. May 4th, 1889. 8*d*.

Furnace Bridge for Boilers.—*B. Darbyshire & J. Entwistle, Bolton.*—The bridge is constructed in sections of terra-cotta or other fire-resisting materials, with an internal air chamber or cavity. Each side of the bridge is provided with openings of any convenient form for the passage of air from the ashpit to and from the internal chamber for the purpose of reducing the temperature of the bridge below that of the fire. The cooling of the bridge minimises the destructive action of the fire and the sticking of clinker. The upper portion of each section is loose to allow of removal to clear the chamber or cavity of dust, &c. Claim: Constructing furnace bridges for steam and other boilers of terra-cotta or other fire-resisting materials in sections, provided with a chamber or cavity and openings as and for the purpose described.—No. 8711. May 27th, 1889. 6*d*.

Lubricators.—*J. Decrance & G. H. Wall, London.*—The lubricator consists of a reservoir for the oil, fitted at its upper part with an oil trap, adapted to be worked intermittently by the attendant when oil is to be fed to the part lubricated. The oil trap is a cylinder, having communication to the working part to be lubricated, and also to the steam supply actuating the working part. A piston in this cylinder can be made by the attendant to close or open these two passages in the cylinder. By suitable connection with the steam supply, the reservoir is provided by condensation with water to take the place of the oil used. The water of condensation falls to the bottom of the reservoir, and forces the oil up to the top of the reservoir and into a part of the cylinder. The oil is thus always under the pressure of the steam in the boiler. By the attendant pushing in the piston the two passages in the cylinder are opened, and the oil in the cylinder trapped and blown out by the steam through the passage leading to the working part. By releasing the handle the parts resume their normal condition, and water of condensation commences to replace the oil just used. Claim: A lubricator having a slide valve mechanism that by a reciprocating movement traps a definite quantity of oil, and gives a flush of water and steam to drive the oil into the part to be lubricated as described.—No. 8715. May 27th, 1889. 8*d*.

Centrifugal Separators.—*W. Hucks, London.*—The separator is for the purpose of separating solids from liquids. The accompanying illustration shows a vertical section of the machine. The parts are enclosed in two circular pans, one inverted over the other, and having a water-tight joint at their circumferences A. Within the chamber formed by these pans is a hollow disc B with inlets and outlets as indicated by the arrows. The disc is secured to the shaft J, and is rotated upon the shaft independently of the chamber. The underside of the disc is covered by wire gauze as indicated by the dotted lines, and by

annular plates C D, C being also fitted with wire gauze. A circular plate E, having vertical radiating blades F, rests horizontally upon the bottom of the chamber. To discharge the accumulated thick matter from the chamber, a lever is provided to lift the top pan from off the lower one, and so form a space through which the matter may escape. The liquid enters the machine at G, passes under the plate E through the wire gauze into the disc, and from the disc is discharged through the passages K. By the rotation of the disc a rotary motion is imparted to the liquid, and through the liquid to the chamber. This centrifugal force keeps the gauze clear and causes the solid matters to collect at the circumference of the chamber. Nine claims are made.—No. 6391. April 15th, 1889. 6d.

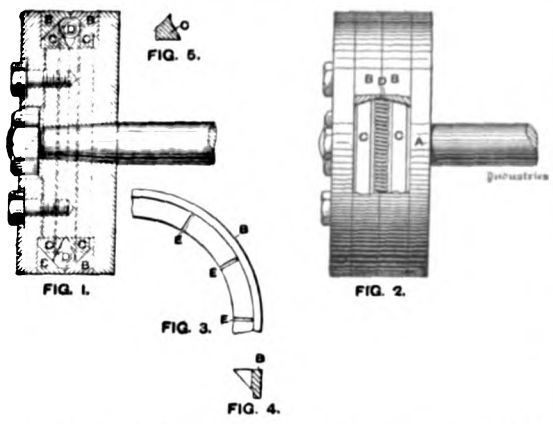
Cylinders, &c., of Carding Engines.—*R. Tatham, Rochdale.*—This invention refers to the surfaces of the cylinders, taker-in rollers, doffers, and other rollers of carding engines. The rollers are made of a tube of steel or wrought iron, or of a sheet of metal bent into a cylinder and its adjacent edges secured to each other. The tube or cylinder is provided with arms of steel or wrought iron, by which it is mounted upon its axle; or discs of metal may be used in place of arms. On the surface of the tube or cylinder, strips of wood or lags are secured by bolts to constitute a surface for fastening the carding cloth to the roller. Claims: (1) For use in carding engines for carding cotton, wool, and other fibrous materials, cylinders, taker-in rollers, and other rollers formed of tubes of steel or wrought iron, or of sheets of steel or wrought iron formed into cylinders or tubes, and provided upon their outer surfaces with lags or strips of wood, or sheets, pieces, or strips of leather or other suitable material, and connected by means of arms of steel or wrought iron to bosses which are split or formed in halves or portions, and secured to the axles by bolts; (2) for use in the cylinders, taker-in rollers, and other rollers of carding engines for carding cotton, wool, and other fibrous materials, axles formed of tubes of steel for the purposes described.—No. 7888. May 11th, 1889. 8*d*.

Making Flexible Metallic Tubes.—*F. Walton, Sunbury-on-Thames.*—The apparatus described in this specification is for making the well-known flexible metallic tubes, which consist of a strip of metal wound helically; the strip of metal is corrugated in such a manner that the lips of the successive convolutions lock each other, having between them a strip of caoutchouc or other suitable packing material, to make the jointing sound as well as elastic. On a lathe head, having a revolving mandrel, is fixed a

Digitized by Google

face-plate, having on its face three roller frames, the frames being at such an angle as to suit the pitch of the helical tube, and of such height from the face of the plate as to suit different parts of the circumference of the helix. Each frame carries a pressing roller, that can be adjusted to or from the mandrel. The axis of each roller has a pinion gearing with a pinion on the mandrel, the gearing being so proportioned that the circumference of the rollers have the same speed as the circumference of the formed tube. The mandrel and rollers are revolved, and the metal strip, after passing between corrugating rollers, is brought with a strip of the packing material, at the angle suitable to the helix, up to the mandrel, and the two are made to revolve with it, undergoing the pressure of the three oblique rollers by which the convolutions are pressed into shape and caused to interlock with each other. As the tube becomes formed, it is caused by the oblique action of the pressing rollers to be pushed continuously off the mandrel. Claims: (1) In apparatus for making flexible metallic tubes, the combination of a revolving mandrel, a face-plate carrying three adjustable pressing rollers inclined to and driven by the mandrel, a reel with guide eyes for the packing strip, and obliquely-set guide rollers for the corrugated metal strip as described; (2) for corrugating the metal strip above referred to, the combination of a plate slotted to guide the flat strip, a pair of corrugating rollers, and a die-plate formed to turn in the edges of the corrugated strip; (3) for supporting the formed flexible tube as it travels and revolves, a revolving pipe through which the tube passes, and in which it freely rolls.—No. 7906. May 11th, 1889.

PISTON RINGS.—*M. Husbands, Stapleford, Nottinghamshire.*—The piston A has two outer expanding rings B bevelled on their surfaces as shown. These rings are expanded by the action of two inner rings C sliding transversely in the recess of the piston, so that the bevelled surfaces of one pair of rings worked against the bevelled surfaces of the others and force them out. The rings C are forced apart by a spiral spring D. To give the expanding rings B more elasticity they are slotted as shown by E in



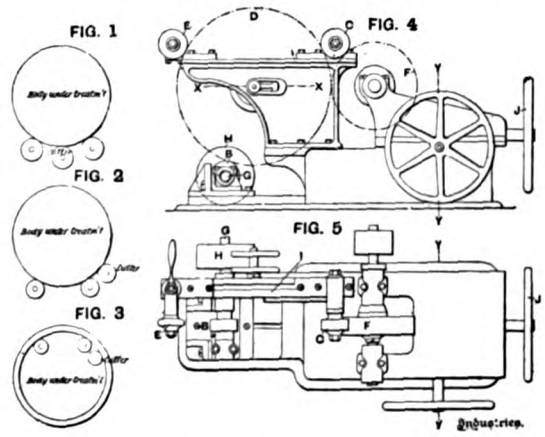


Fig. 3. Claims: (1) In a piston or the like the employment of a ring such as C having outer and inner bevelled surfaces as and for the purpose described; (2) in a piston or the like the combination with the outer expanding rings B of rings such as C provided with inner and outer bevelled surfaces as and for the purpose described; (3) in a piston or the like the combination with rings such as C provided with inner and outer bevelled surfaces of a spring such as D substantially as described and illustrated in the accompanying drawings; (4) in a piston ring having an inclined face such as described the employment of radial cuts or openings such as E as and for the purpose described and illustrated in Figs. 3 and 4; (5) the combination and arrangement of parts forming the complete packing for pistons and the like substantially as herein described and illustrated in Figs. 1 and 2.—No. 9340. June 5th, 1889. 6*d.*

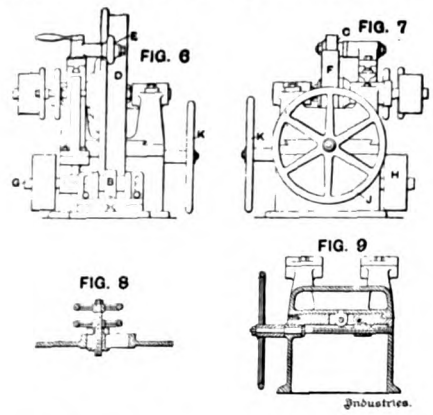
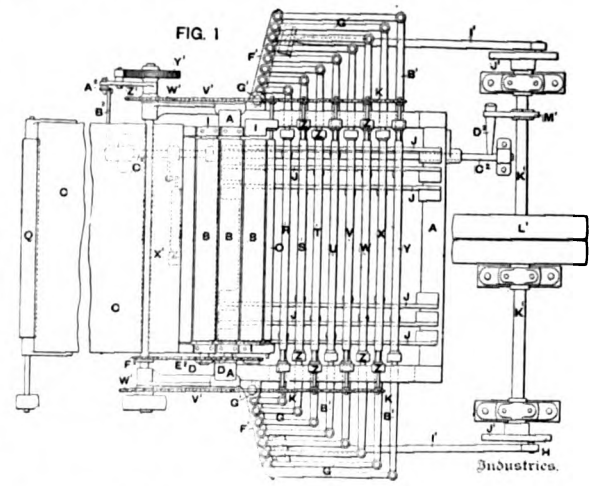


NAVIGABLE VESSELS.—*A. Clerk, London.*—The invention consists in providing the sides and bottom of the hull with longitudinal corrugations or ribs projecting from the surface of the hull so as to be acted on by the rising and falling motions of the waves in such manner that these opposite motions counteract each other. In the practical application of the invention the hull is plated or sheathed with corrugated sheets of metal, or by affixing to the sides and bottom longitudinal ribs of L or T iron, the corrugations or ribs being truly parallel with the line of flotation of the vessel. Claim: The application to ships' hulls of longitudinal ribs or longitudinal corrugated plates, substantially as specified, so as to roughen the outer surface of the hull in the circumferential direction, whilst leaving it smooth in the longitudinal direction, whereby to lessen rolling or rolling and pitching motions without opposing the progress of the hull through the water.—No. 9423. June 6th, 1889. 6*d.*

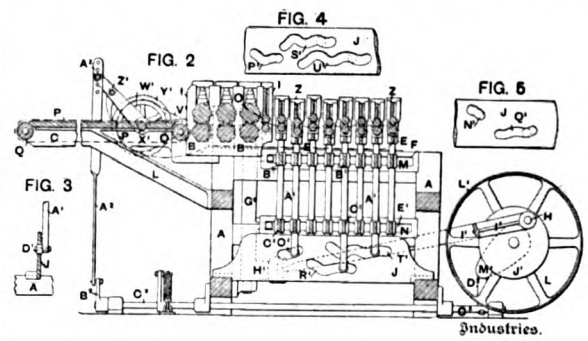
DIRECT-ACTING STEAM PUMPS.—*W. Holker, Liverpool.*—The class of steam engines here referred to is that in which the valve is worked by means of a rocking lever actuated by a tappet during the strokes of the engine. The engine is fitted with an ordinary slide valve actuated by a T-shaped lever. The lever is pivoted to the cross-head guides like a T reversed, and at the centre of its upright. At the end of the upright the valve rod is connected, and at each end of the cross-piece is a sliding pin. The pins slide in holes whose direction is downwards but towards a vertical line drawn through the centre of the lever; they are pressed downwards by springs, and protrude slightly from the lower surface of the cross-piece. The lower surface of the cross-piece inclines downwards from its centre to its ends, and its ends beyond the sliding pins are also turned slightly downwards. As the cross-head travels backwards and forwards, a pin in it works upon the lower surface of the lever, and, by reason of its inclined surface, rocks the lever and moves the valve. The pin, as it approaches the end of the rocking lever, presses in the sliding pin and at the end of its path comes under the turned-down end of the lever and opens the valve sufficiently to give a lead. The cross-head and its pin then travel backwards, but in passing over the sliding pin this time does not press it backwards by reason of its inclination, but causes the lever to be still further rocked and the valve to be opened full. The valve remains in this position until the cross-head passes the centre of its path; the pin then strikes the other inclined surface of the lever, and rocks it over until the valve is closed and similar operations recommence at the other end. Four claims are made.—No. 8089. May 15th, 1889. 8*d.*

REDUCING BODIES TO A CIRCULAR FORM.—*W. P. Thompson, Liverpool.* (*J. N. Barn, Milwaukee, U.S.A.*)—This invention is based upon the fact that a circle of certain diameter and no other will touch three points in given relation to each other. The machine involves the use of two or more rollers to serve as peripheral supports to the body under operation, and an abrading wheel or cutter located in such relations to the supports as to act on the periphery of the body revolved between them. Two of the rollers represent two of the points, and the abrading wheel the third point, which the body touches simultaneously when

reduced to the proper diameter. In the illustrations are shown Figs. 1, 2, and 3, diagrams of the different arrangement of the cutter and wheels, Fig. 4 a side elevation of a machine, Fig. 5 a plan, Fig. 6 an end elevation, Fig. 7 an opposite end elevation to Fig. 6, and Figs. 8 and 9 sectional details on the lines X X Y Y. Two rollers B C are mounted upon bearings of any suitable character, and support the approximately circular body D to be trued. An emery wheel F is mounted between the rollers to grind the body to the required state. The grinder F and the rollers B C occupy such position that their active surfaces touch a circle of the required size. By this arrangement it follows that the body revolved upon the supports will be reduced by the grinder until it acquires a true circular shape, when the action of the grinder ceases. The rolling support B consists simply of a wheel or pulley carried by a horizontal shaft G, which is driven by the belt pulley H. The rollers C and E have a horizontal adjustment upon the surface I to permit the variation of the



diameters of the bodies treated. The roller E keeps the body against the other rollers and the abrading tool. The tool F has a longitudinal and transverse horizontal sliding adjustment, and is manipulated by the hand-wheel J K. Seven claims are made.—No. 2629. February 18th, 1889. 8*d.*



SLIDE VALVES.—*P. Brotherhood, London.*—The object of this invention is to simplify the construction and action of slide valves for steam and other fluid engines, and to obtain a large area of passage for the working fluid consistently with small clearance space in the passages to the cylinder. For these purposes the slide valve is subdivided into a number of separate valves, each in the form of a piston valve governing a circular hole close to the cylinder port. These piston valves are all connected to one operating rod which may be worked by an eccentric or other gear. The valves are arranged radially around the cylinder with their axes parallel to that of the cylinder. They are about the same length as the cylinder, and their ends constitute the valve faces. All the valves are enclosed in the same chamber, to which steam is supplied and surrounds the valves before escaping past their ends to the cylinder. The exhaust takes place through the valves which are made tubular with open ends. Claims: (1) Constructing the slide valve of a steam or other fluid pressure engine in several separate parts, each consisting of two connected pistons working through circular holes close to the cylinder ports, and all the rods of these pistons being connected to the main slide rod; (2) the construction of slide valves for a single cylinder in several separate parts attached to one main slide rod, each part consisting of two connected pistons working through circular holes close to the cylinder ports; (3) the construction of slide valves for a compound engine, the valve for the high-pressure cylinder in several parts, and the valve for the low-pressure cylinder in several other parts, each of these parts being in the form of connected pistons working through circular holes close to the cylinder ports and all these connected pistons being connected to one main slide rod; (4) the construction of slide valves for two cylinders side by side, the slide valve for each cylinder being divided into several parts and all the connected pistons for each cylinder being connected to one main slide rod as described.—No. 3485. March 4th, 1890. 8*d.*

GLASS-LINED TUBE FITTINGS.—*D. Rylands, J. Crowder, & R. Morant, Barnsley, Yorkshire.*—By this invention a T piece is constructed in a convenient and efficient manner with a continuous glass lining. The metal shell or casing of the T piece is composed of ordinary metal piping, the cross-piece being provided with a screwed hole midway between its ends for jointing up the stem piece. The casing so constructed, after being internally coated with glass, may be laid in a mould and metal cast around it to form a strong protecting coat. To line the piece with glass a glass tube of rather smaller external diameter than the internal diameter of the case is inserted in the cross-piece with its ends flush with the ends of the case. The ends of the glass tube are then stopped by corks, one cork having a hole for inserting a tube, and the other cork being pierced by a centre. The centre and tube thus inserted in the corks hold the glass tube and the casing horizontally in a fork-shaped frame. The T piece is now placed over a flame, so that the flame enters the unstopped hole and softens the glass at the joint. When the glass has become softened, air is blown into the glass tube through the tube penetrating the cork, and a hole is blown in the glass to accommodate the third opening. The glass thus blown forms a flange round the inner part of the stem of the T piece. A second piece of glass is now taken and inserted in the stem, and its inner end fused to the flange formed on the first tube. The space between the metal casing and the glass tubes is filled up with a cement or any suitable substance. Four claims are made for the method of constructing glass-lined tube fittings as described.—No. 6750. April 20th, 1889. 8*d.*

MACHINES FOR TREATING FLAX, &c.—*A. Spiegelberg, Dundee.*—The object of this invention is to substitute for the ordinary scutching process machinery that will act in a superior and more expeditious manner. The flax is passed through a series of

rollers, having, besides a rotary, a vertical and horizontal movement. Fig. 1 of the illustrations is a plan, and Fig. 2 a longitudinal sectional illustration of this machine. Figs. 3, 4, and 5 are details of the machine. Upon the upper part of the framing A are three pairs of preparatory pressing rollers B. Beyond the pressing rollers is a feed-table C, having an endless feed-apron P, which feeds the flax to the rollers B. The flax, after passing the rollers B, enters successively between eight pairs of breaking rollers, R to Y, which are horizontally and vertically reciprocated. Each pair of these breaking rollers is carried by a transverse bar, supported in spring bearings Z in the vertical rods A^1. The vertical rods A^1 give the breaking rollers their vertical motion, the ends of the rods carrying bowls which work in the slots of a cam-plate J. The ends of the rods supporting the breaking rollers are connected to horizontal rods G, which are pivoted to a lever F^1. The lever F^1 is fast to a spindle in the frame G^1, and receives an oscillating motion from the crank pin H of the plate J^1. The rollers are driven by endless chains V^1 and E^2, to which motion is transmitted from the driving shaft K^1, through the ratchet wheel Y^1 and the shaft X^1. By this arrangement

the breaking rollers, as they are moved longitudinally by the levers F^1, are also moved vertically by the bowls running in the slots of the plates J. From the nature of the connections it will be seen that the vertical and horizontal movements of the breaking rollers are of varying speeds. Claims: (1) The combination of parts constituting the improved machine for breaking or treating flax and similar textile materials as described; (2) for breaking or treating flax and similar textile materials, combining a number of pairs of nipping rollers, through which the materials are moved progressively with mechanism imparting to such pairs of rollers longitudinal and vertical reciprocations.—No. 7031. April 27th, 1889. 8*d.*

HOT WATER COILS.—*W. G. Cannon, London.*—In a previous specification the inventor has described a form of coil for heating purposes; the present invention is an improved form to facilitate the erecting and detaching of the parts. The coil or heater is composed of two longitudinal box-like vessels, one to form the top and the other the bottom of the heater. These vessels are

Digitized by Google

provided with a series of holes or sockets upon their sides, arranged in a straight line, and those in the top chamber corresponding with those in the lower. Cast-iron tubular pieces connect these two chambers. They have cast upon the back of their upper and lower ends, and at right angles to their lengths, short tubular pieces, which fit the holes or sockets in the longitudinal box-like vessels. The short tubular pieces are surrounded by rubber rings or other packing material previously to being inserted, and they are held firmly in their sockets by a bolt passing through each end of the tubular chamber through the longitudinal vessel, and an opposite tubular chamber upon the other side of the vessel. Claims: (1) In steam and hot water coils or radiators of the above description, the improved construction of pipes whereby the junctions are made vertical for the purpose of facilitating the setting up, removal, or renewal of one or more vertical pipes, without disturbing the remainder; (2) in combination with steam and hot water coils or radiators of the above description, the improved air chambers, whereby fresh air is introduced to the apartment and warmed by contact with the heated pipes; (3) the general construction of the several and respective parts together constituting the improvements in the construction of steam and hot water coils or radiators, and in the utilisation of the same for warming and ventilating.—No. 7684. May 8th, 1889. 8*d*.

ELECTRICITY.

GALVANOMETERS.—*F. V. Andersen, Catford, Kent.*—This instrument has a comparatively long and consequently powerful magnetic needle which is suspended within the deflecting coils in such a manner that the coils intercept practically all the magnetic lines of the needle in whatever position it takes. A long indicating needle is mounted upon an axis making a small angle with the magnetic or longitudinal axis of the needle. The magnetic needle may be either a permanent magnet or magnetised by special coils. In the accompanying illustration, Fig. 1 is a vertical section of the instrument; Fig. 2, a plan; Fig. 3, a method of winding the deflecting coil when the instrument is used for measuring the differences of potential between points of electric circuits; Figs. 4 and 5, another method when used for measuring the resist-

FIG. 1

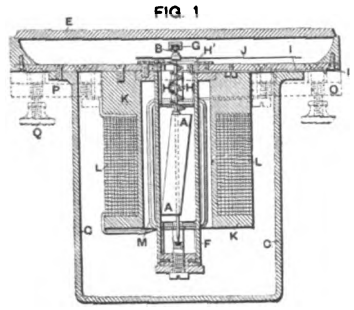


FIG. 4

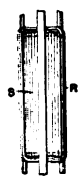

FIG. 5

FIG. 2

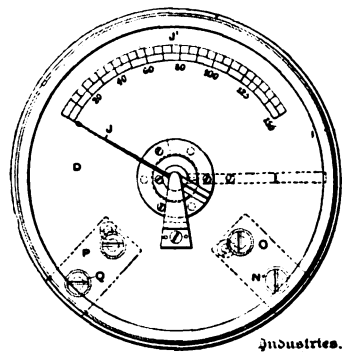

FIG. 3

ance of an electric circuit. The needle is composed of a thin blade A, of soft iron, to which is secured a non-magnetic spindle B, making a small angle with the direction of length of the needle. The instrument is enclosed in a metal case C, preferably of cast iron. In the centre of the case is attached to its cover D a tube F of non-magnetic metal. Within the tube F the magnet is pivoted. A spiral spring H is attached by its lower end to the magnet spindle, and at its upper end to a movable ring H¹. By a lever I the ring H¹ can be turned to adjust the indicating needle secured to the top end of the spindle. The coils for exciting the needle are wound upon an insulating reed K surrounding the needle. The deflecting coils M are wound upon the tube F. The circuit of the instrument is from the terminal N, through the plate O, deflecting coils M, exciting coils L, and plate P to the terminal Q. When the instrument is used to indicate difference of potential, the terminals N and O are connected to the points of the circuit, and the needle is deflected against the resistance of the spring H. The amount of deflection is indicated by the pointer J on the scale J¹, which is suitably graduated to read the difference of potential in volts. When the instrument is required to measure the resistance of a circuit or of a portion of a circuit the tube F is wound with two sets of coils R S arranged at right angles to one another as clearly shown in Figs. 4 and 5. One of these coils, say, R, is put in the circuit in series with the resistance to be measured, and the other coils S and the exciting coils L are arranged in series as a shunt to the resistance. In this arrangement the spring H is dispensed with. The deflection of the needle to either side of its symmetrical position with respect to the coils R S will be indicated on the scale J¹, which is then suitably graduated to read ohms. Four claims are made.—No. 5010. March 22nd, 1889. 8*d*.

ELECTRIC CUT-OUTS.—*W. J. S. Barber-Starkey, Bridgnorth, Shropshire.*—An automatic cut-out constructed according to these improvements is intended to open a circuit when the pressure on it exceeds or is in defect of a predetermined range of voltage. In carrying out the invention a small magneto or electro motor is included in a high resistance shunt from the dynamo or mains. By means of stops or equivalent devices the possible angular motion of the armature of the motor is limited, so that it does not rotate continuously when its circuit is closed. The spindle of the armature is geared or connected with a switch for opening and closing the main circuit. In the apparatus represented in Figs. 1 and 2 the electro field magnets and armatures should be wound

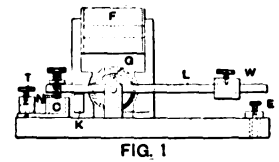

FIG. 1

FIG. 3

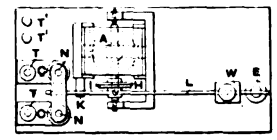

FIG. 2

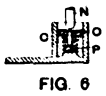

FIG. 6

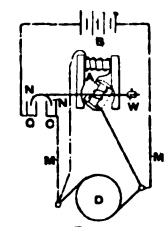

FIG. 4

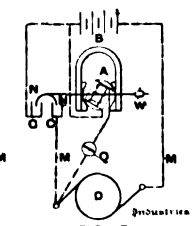

FIG. 5

in shunt with high resistance wire so as to employ only as much of the current as will be effective for the operation of the motor at the determined pressure. A lever L is connected with the spindle of the armature, and carries two prongs N N, which have adjustable screws as indicated. On the other end of the lever is a weight W which may be adjusted at any desired part of the lever between the motor and the end of the lever. The angular position of the armature relatively to that of the lever L may be adjusted by the screw G. The mercury cups O are insulated from each other, and are respectively electrically connected with the two terminals T T, which are in turn electrically connected with the two ends of the main cable or conductor which is to be opened or closed by the apparatus. Assuming that the terminals T T are connected with the main circuit and the terminals T¹ T¹ with the shunt and motor circuit, and that the lever rests with its weighted end on the stop E so that the prongs N N are out of the mercury cups C, when the e.m.f. in the dynamo circuit M M reaches a predetermined amount, the intensity of the magnetic field just suffices to enable the armature to rotate in opposition to the tendency of the weight W. The movement of the armature once commenced it increases rapidly, and the prongs N N are forced down into the cups, thus completing the main circuit. The apparatus may be joined up as represented diagrammatically in Figs. 4 and 5. In Fig. 4 it is joined in shunt to the dynamo terminals, and in this case the e.m.f. actuating the apparatus is that of the dynamo D. In Fig. 5 one of the terminals of the apparatus is joined to one of the poles of the dynamo D and

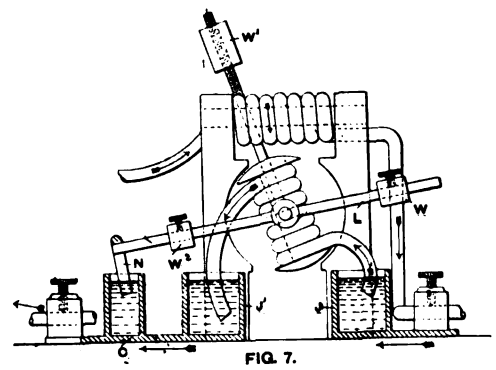

FIG. 7.

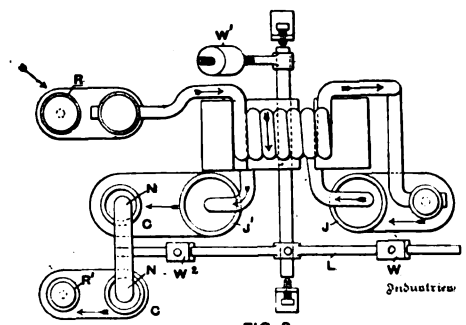

FIG. 8.

the other to the corresponding pole of the secondary battery or accumulator B which is being charged or is in circuit with the dynamo. When the apparatus is employed as a main circuit cut-out it is preferably constructed as shown in Figs. 7 and 8. The armature is wound with a conductor having a sufficient cross section to carry the main current safely. The current enters at the terminal R, traverses the field magnet coil, the mercury cup J, the armature coils, the mercury cup J¹, and the two mercury contact cups C C to the terminal R¹. The lever L, the prongs N N, and the mercury cups C C may be constructed and arranged as described with reference to Figs. 1 and 2. If the current exceeds a certain predetermined amount, the motion of the armature breaks the main circuit. Seven claims are made.—No. 8493. May 22nd, 1889. 8*d*.

FOG SIGNALS.—*F. A. Harvey & M. E. Brooke, London.*—Two metal lines are placed between and parallel to the rails. These lines are in connection with an electric bell and battery and a switch situated in the signal box. To the under part of the locomotive are secured two metal wheels or discs arranged to travel over in electrical contact with the two metal lines. The wheels are supported in brackets made to slide in cylinders, and are pressed downwards by coiled springs. The two wheels are electrically connected with an electric bell fixed in the cab of the engine. The electric circuit being connected by the switch in the signal box, the wheels as they travel over the metal lines complete the circuit, and the bells ring simultaneously in the engine cab and the signal box. Claims: (1) The combination with two lines of insulated metal in electrical connection with the signal box of wheels carried by the engine and bearing upon the insulated lines completing the electric circuit through the engine as described; (2) in apparatus such as referred to in claim (1) mounting the wheels upon pistons working in cylinders and pressed downwards by springs; (3) electric fog signalling apparatus for railways as described.—No. 9066. May 31st, 1889. 6*d*.

BEARINGS.—*H. J. Elliott, London.*—This specification describes a small appliance for giving warning of the over-heating of bearings, &c. In a small cylindrical box is arranged a short metal rod concentric with the axis of the box. The box is screwed to the bearing or part whose overheating it is to give warning of. One end of the rod is supported in an insulated socket at one end of the box, and the other end presses against an intercepting block of insulating material at the other end of the box. The insulating material is of such a nature as to liquefy when the part of the case enclosing it becomes heated to a certain extent. The wire is included in an electric circuit that works an alarum, and completes the circuit when the insulating material melts, by being pressed in contact with the metal case also included in the circuit. Claim: The combination of means as described, whereby a piece of shellac, gutta percha, sealing or paraffin wax, or some similar material or combination of two or more of them, liquefying by heat, or a disc of fusible alloy melting at a low temperature mounted in an insulating ring, so as not to touch the bottom or the sides of box, is interposed between the point of a spring wire and the metal box, and consequently with the battery, the softening or melting of which allows the completion of circuit with electric bell and indicator.—No. 9423. June 6th, 1889. 6*d*.

ELECTRO-MECHANICAL MOVEMENTS.—*S. E. Nutting, Chicago, U.S.A.*—The object of this invention is to construct an electro-mechanical movement that will be proportional at all times to the quantity of the electric current. In one form of this invention, where the motion to be regulated is the descent of a weight, the weight is suspended by a cord wound upon a sheave. Attached to one side of the sheave is a disc composed of beeswax, tallow, stearine, or other softenable substances. As the weight descends the sheave and disc of beeswax rotate. Through the disc a wire is passed at right angles to its face and close to its periphery. This wire prevents the disc rotating until the wire is sufficiently heated by the electric current to melt the wax. As the current increases the wax melts with greater rapidity, and the weight descends faster; upon a decrease in the current the action is reversed. In another form of apparatus the wire heated by the electric current is made to pass through the length of a stick of beeswax enclosed in a tube. The tube is slotted upon diametrically opposite sides for the wire to pass through.—No. 2234. February 11th, 1890. 8*d*.

CHEMISTRY.

ALLOYS OF ALUMINIUM—*G. Bamberg, London.*—The inventor obtains alloys of aluminium with iron or copper by first melting down the iron or copper, and acting upon it with an air blast in a similar manner to the Bessemer process, for the purpose both of removing impurities and raising the heat of the metal to a high degree by the combustion of the carbon and silicon contained therein. Vapours of chloride of aluminium or of double chloride of aluminium and sodium are then injected, or such materials in a fine state of division, which when exposed to the temperature of fused iron or copper shall produce vapours of chloride or double chloride. The molten iron or copper at a very high heat will decompose the chlorides of aluminium, producing chloride of iron or copper, which pass off as vapour, while the liberated aluminium, being in a nascent state, combines intimately with the fluid metal. Claim: Producing alloys of aluminium with iron or copper, by first melting down the iron or copper, and, after raising its temperature to a high degree by the injection of air blast, injecting into the same vapours of aluminic chloride or of the double chloride of aluminium and sodium, or of materials that will produce such chlorides when subjected to the heat of the molten iron or copper, substantially as herein described.—No. 7666. May 8th 1889. 4*d*.

MISCELLANEOUS.

HEMP ROPES.—*M. H. Tomkins, London.*—European hemp and Manilla hemp have different qualities. Thus the European hemp is as strong or stronger than the Manilla, whereas the Manilla is better able to resist friction. To make use of these qualities in the manufacture of rope, the inventor makes the core of European hemp and covers it with Manilla. In combining the yarns of these two hemps to form strands, a machine of the ordinary construction is used, and two guide plates are used set at five feet apart. The yarns are threaded through the plates on their way to be twisted into a strand. The two kinds of hemp yarns are threaded through these plates so that the one is covered by the other as the strand is formed. Claim: The manufacture of ropes from compound strands prepared from different qualities of hemp in the manner described.—No. 8951. May 22nd, 1889. 8*d*.

Copies of the British specifications may be obtained on application to H. READER LACK, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

IMPROVED SLOTTING MACHINE.

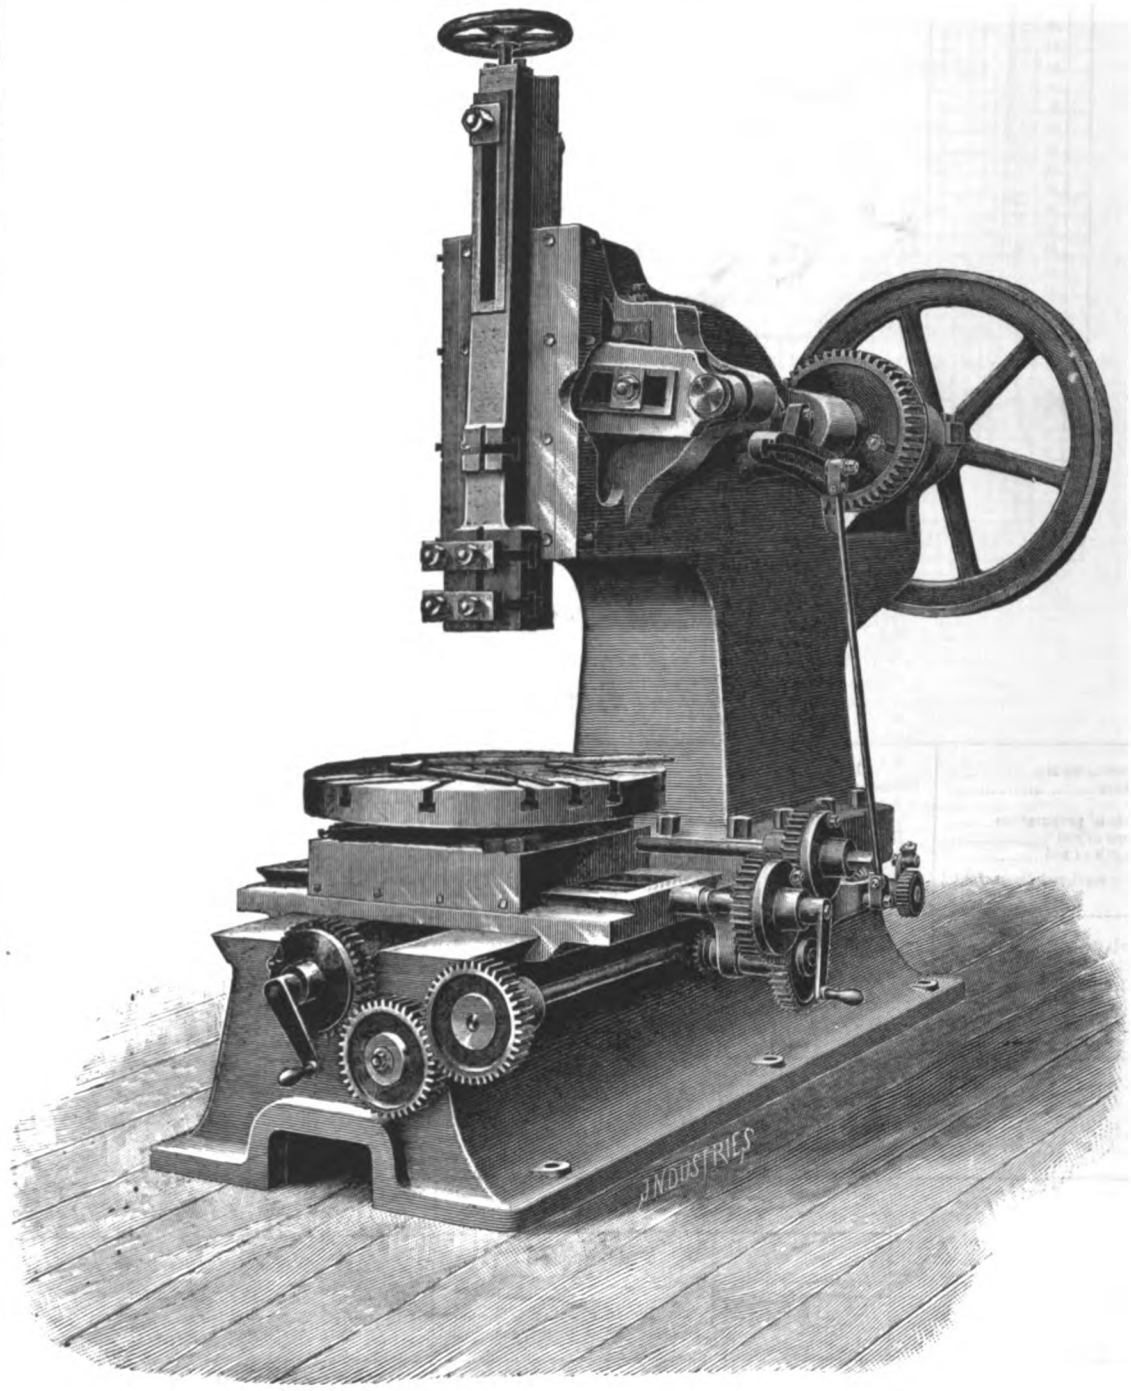
We illustrate herewith a powerful slotting machine made by Messrs. Crooks, Roberts, & Co., Argus Works, Sheffield, for Messrs. Joseph Ashforth & Co., Ld., Bruce Works, and designed by Mr. Thomas Peregrine Hill. The machine weighs about seven tons, and will take in a casting 8ft. diameter and 20in. deep. It has a 16in. stroke, and is fitted with a cast steel quick return arrangement. The ram is cast of a strong box-section shape, and planed out to take in 2in. round or square steel tools. It is driven by a four-speed cone capable of carrying a 3¾in. belt, and has double-geared cast steel back gear. A suitable fly-wheel is keyed to the main spindle, so that a good cut can be taken without the back gear being used. The body and bed of the machine are cast separately and jointed by planed surfaces. At each side, and also in front, heavy lugs are cast to receive strong iron hoops, which are shrunk on. The compound table is fitted up as usual, but is also supplied with extra deep and strong slides. The feed motion is obtained by an arrangement due to Mr. Wm. Wares, which feeds when the ram is at its highest point. All the wearing surfaces are case-hardened, and in every way the workmanship is good. Messrs. Ashforth have already tested the machine by using it for the blades and boss of a 10-ton propeller for a screw gunboat.

ON THE CRITICAL POINTS OF IRON AND STEEL.*

If iron and steel are submitted to a gradual heating or to a slow cooling between the ordinary temperature and that of fusion, and if the variations of some physical property in relation to the temperature are followed, it will be seen that these variations, besides being subject to a constant law, present remarkable phenomena at certain critical temperatures. In order to find in scientific literature the first reference to these anomalies it is necessary to go back to Gilbert, who discovered in 1600 that when a magnet is heated to redness it loses all traces of magnetism. It is, however, not my intention to refer here to the history of the question. This has been admirably summarised by Professor Roberts-Austen, in a lecture delivered at the Newcastle meeting of the British Association in 1889. I will merely give at the end of this paper a list of original memoirs which have been published, to my knowledge, during the last twenty years, and in which English science, represented by Gore, Barrett, Tait, Tomlinson, Hopkinson, and others, has taken a considerable part. When I commenced, in October, 1886, to study the critical points of iron, a certain number of important facts were already known. But as the first experimenters did not possess the means of accurately determining high temperatures, and as they did not, as a rule, make analyses of their samples, it was difficult to make a comparison of their results, and to decide what was the share of iron and of carbon respectively in the results observed. It was, therefore, necessary to collate the known facts rather than to discover new ones. This is what I propose to do in determining as accurately as possible the position of the critical points, their causes, and their relations to each other.

It was known at the commencement of the research that the phenomena to be studied were the results of either chemical reactions or allotropic changes, or both. But as all these phenomena are indicated by a liberation or absorption of heat, I thought that the classic method of cooling would be the most suitable for my purpose. A series of samples of suitable chemical composition were heated to a known temperature, and accurate measurements were made, during their cooling, of the time required for the temperature to be lowered an equal number of degrees. Every abnormal delay or acceleration in the fall of the thermometer should indicate a liberation or an absorption of heat, or, in other words, a critical point. The measurement of the time presented no difficulty. This was not the case with the measurement of the temperature. I was fortunate enough, however, to be able to employ the thermo-electric pyrometer, which has recently been devised by M. H. Le Chatelier, and which proved to be thoroughly well adapted for my researches. This apparatus is made by Carpentier, 20, Rue Delambre, Paris, and is described in the *Journal de Physique*, Vol. VI., January, 1887, and in the *Génie Civil*, 5th March, 1887. Le Chatelier's couple is formed of a wire of pure fused platinum and a wire of platinum alloyed with 10 per cent. of rhodium, fastened together at one end. The opposite ends, maintained at a constant temperature, are connected by means of copper conductors to the aperiodic mirror galvanometer of Messrs. Deprez and D'Arsonval. The apparatus is first calibrated by means of well-known melting and boiling points. The melting-point of potassium sulphate (1,015° C.) and the boiling-point of ammonium chloride (340° C.) are particularly well adapted for the purpose. It may be assumed that between these two points, and for higher temperatures up to 1,500° C., the temperature is proportional to the electromotive force of the couple, and to the deviation from zero of the spot of light from the mirror on the graduated scale of the galvanometer. This having been arranged, the experiment is conducted in the following manner.

The metals to be studied have the form of round or square bars, 5 to 7 millimetres (0·2in. to 0·28in.) in diameter or side, and at one of the ends of the bar F a small recess is filed or ground, according to the hardness of the metal, of a shape suitable for soldering the thermo-electric couple. (See Fig. 2, page 482.) A piece F′ of the same metal, 3 to 4 centimetres (1·18in. to 1·575in.) in length, and prepared in the same way, was brought over the couple, placed in position in such a way that the junction was squeezed between the rods F and F′, or the whole was firmly bound up with iron wire. (See Fig. 3.) Fig. 1 is a diagrammatic sketch of the complete installation shown in plan. The rod F is introduced into a porcelain tube in such a way that the connection may be placed in the centre of the furnace S. The platinum and platinum-rhodium wires are isolated by clay tubes. The porcelain tube is closed at both ends with cork, and through one the rod and the wires of the couple are passed. Air is thus prevented from freely circulating in the tube, and under these conditions the oxidation is very slight, so that the same rod may be submitted without appreciable alteration to a large number of successive heatings and coolings. The ends of the wires of the couples soldered to the copper conductors are placed in two test tubes filled with alcohol, and inserted in a water bath E, the temperature of which is that of the cold joint. G represents the galvanometer with its mirror *m*, L is the lamp, R the graduated scale with its reflector M. The dotted line LM*m* indicates the path of a ray of light sent by the lamp to M, reflected from M on to *m*, and thence on to the scale. In order to conduct an experiment, the furnace is heated to the desired temperature. When this temperature is obtained, the gas is extinguished, the whole system is allowed to cool spontaneously, and with the aid of a chronograph the moment at which the index passes across each of the divisions of the scale is noted. The error in reading amounts at most to one-twentieth of the time that elapses between two successive pointings. In order to represent the results graphically, I take the temperatures as abscissæ, and, as ordinates, the times included between the passages of the index over two consecutive divisions of the scale. These divisions are shown in the diagrams accompanying this paper by the ordinates of the corresponding temperatures, and the point representing the time occupied between two pointings is placed in the middle of the interval. A retardation or arrestation (*relentissement*) in the fall of temperature will thus be shown by a sharp point, and a delay in the cooling by a bulge in the curve—a bulge of which the area is proportional to the quantity of heat liberated.



(A) Phenomena Observed during the Slow Cooling of Iron, Steel, and White Pig Iron between 1,100° C. and 600° C.—I shall first study a series of samples with an increasing proportion of carbon, the other constituents remaining, as far as possible, in low and but slightly varying proportions. Table I., on the next page, shows the results of analyses of the samples.

For convenience in describing and discussing the phenomena observed, I shall designate by the letter *a*, with Tchernoff, the critical points that are associated with the hardening of steel. But, as my experiments show that the point *a* of Tchernoff is not a single point, and that there may exist several adjacent critical points of different natures, I shall term these different points a_1, a_2, a_3, of which a_1 is applied to the perturbation produced at the lowest temperature. As, too, the same perturbation is not distinctly developed at the same temperature when the thermometer rises as when it falls, it will be necessary to distinguish a critical point, a_{r1} for example, observed during cooling (*refroidissement*), and the corresponding point a_{c1} observed during the heating (*chauffage*). In this notation *a* indicates the critical point; *r*, *refroidissement*; *c*, *chauffage*, and the numbers the positions in the thermometric scale. A symbol such as $a_{r(1\text{-}2)}$ will indicate that in the sample under consideration the two points a_{r1} and a_{r2} are combined into a single one. A symbol such as a_{r1}/m will indicate that the perturbation a_{r1} is incomplete. Besides the points *a*, there are in grey pig irons other critical points due to the successive solidification of different constituents. These points, perhaps, have their analogues, although very indistinctly marked, in steels. But even admitting that the existence of these small perturbations is certain, and although their theoretical and practical importance might be considerable, their true nature is hypothetical, and it seems to me preferable to neglect them for the present. Lastly.

* Paper read by Monsieur F. Osmond, of Paris, before the Iron and Steel Institute on the 8th inst.

as certain terms may be interpreted differently, it is advisable to accurately define the sense in which I employ them. I apply the term *hardened steel* (*acier trempé*) to steel that has been rapidly cooled from a red heat. *Annealed steel* (*acier recuit*) is steel that has been heated to a red heat and cooled slowly. *Tempered steel* (*acier revenu*) is steel that, after hardening, has been softened, more or less, by reheating to a temperature far short of that to which it was raised before hardening. Having decided on the symbols to be adopted, I shall now pass to a description of the facts. (See Fig. 5.)

Sample No. 1, *Electrolytic Iron.*—Strip cut from a plate and annealed at a cherry-red heat in hydrogen before testing, in order to expel occluded hydrogen. Contrary to expectations, this electrolytic iron was found to contain a little carbon (0·08 per cent.), the presence of which has been verified by two different methods of analysis. Notwithstanding this, of all the metals examined, this iron approaches most closely to a state of absolute purity. During the cooling, the thermometer stops abruptly at 885° C., and makes a prolonged stay a_{r3} at this temperature. It then resumes, also abruptly, its downward course. A gradual arrest in the fall of temperature, commencing at 750° C., presents its first principal maximum between 737° C. and 730° C., its second subsidiary maximum between 708° C. and 702° C., and ends at about 690° C. Lastly, a final arrest a_{r1} is produced at about 660° C.; but it is almost imperceptible, and it might be confounded with experimental errors were it not found again, considerably amplified, in steel.

Sample No. 2, *Extra-Mild Steel.*—The course of the cooling presents three arrests, all of which are gradual, and their phases are as follows:—

	Commencement.	Maximum between.		Conclusion.
a_{r3}	845° C.	825°-819° C.	...	800° C.
a_{r2}	755° C.	736°-725° C.	...	710° C.
a_{r1}	680° C.	662°-655° C.	...	645° C.

Sample No. 3, *Mild Steel.*—There are two arrests in the fall of temperature:—

	Commencement.	Maximum between.		Conclusion.
$a_{r(3\text{-}2)}$	780° C.	721°-715° C.	...	690° C.
a_{r1}	680° C.	660° C.	...	640° C.

Sample No 4, *Medium Steel.*—There is one gradual arrest and one stay. The arrest $a_{r(3\text{-}2)}$ commences at about 750° C., reaches its maximum between 700° C. and 690° C., and before being completely terminated halts at the station a_{r1} at 661° C.

Sample No. 5, *Hard Steel.*—The slight arrest in the cooling a_{r3}/m, which is directly produced at about 860° C., in the curve given as example, is exceptional for the steel examined. It is an accidental fact which it was found advisable to note. The characteristic of hard steel is a single break of long duration $a_{r(3\text{-}2\text{-}1)}$, at 674° C. The stay is accompanied by an arrest in the fall of temperature which precedes and follows it, but uniting with it (commencement at 720° C., end at 645° C.).

Sample No. 6, *White Pig Iron.*—Solidification point 1,085° C. The critical points of steels are represented by a single stay, $a_{r(3\text{-}2\text{-}1)}/m$, which is exhibited at 695° C., and which unites in a continuous manner with an arrest commencing at about 710° C. and ending at about 660° C.

We are now enabled to discuss these results, which are all plotted in Fig. 5. A glance at the superimposed curves shows that the station a_{r1} goes on increasing from the electrolytic iron, where it is almost *nil*, up to the hardest steel, where it assumes enormous importance. Thus, a is a function of the proportion of carbon, and it may at once be identified with the phenomenon to which Barrett, who discovered it in 1873, applied the name of *recalescence*. Nevertheless, in the examples I have given the temperature remains nearly stationary, and does not rise as it did in Professor Barrett's experiments. This difference is unimportant. For the same steel it is possible to have indifferently recalescence, stay, or simple retard, according to the relative velocities of the cooling and of the reaction which liberates the heat, the reaction itself being more or less rapid according to whether it was more or less retarded. These phenomena are analogous to those of surfusion. The cause of the liberation of heat, which takes place at a_{r1}, may easily be determined. Indeed, Brinell's researches have shown that the carbon of steel is in the state of *hardening carbon* (*carbone de trempe*) below a_{r1}, and that it is in the state of *cement carbon* (*carbone de cémentation*) above that temperature. Thus, the recalescence a_{r1} represents the change of hardening carbon into cement carbon, and this change is effected with a violent evolution of heat. It is known, too, from the researches of Dr. Müller (*Zeitschrift des Vereines deutscher Ingenieure*, Vol. XXII., p. 385; *Stahl und Eisen*, Vol. VIII., p. 291) in Germany, of Sir Frederick Abel and Mr. Deering (*Institution of Mechanical Engineers' Proceedings*, 1885, p. 30) in England, and of Messrs. Osmond and Werth (*Annales des Mines*, 8th Series, 1885, Vol. VIII., pp. 5–84) in France, that cement carbon, termed also *carbide carbon* (*carbone de recuit*), is combined with the iron in the form of a compound probably having the definite composition Fe_3C. The true state of the hardening carbon is less accurately known, but it appears probable that it is that of free carbon simply dissolved in the iron, or perhaps that of hydrocarbon. Thus a new and more precise definition of recalescence may be given as follows:—*The liberation of heat which produces recalescence is the result of the chemical combination of the iron with the carbon; and conversely the absorption of heat during heating a_{r1} corresponds to the dissociation of the carbide Fe_3C, a compound which is stable at low temperatures.* It is in this way that carbonic anhydride and lime combine or separate, according as the temperature is lower or higher than the dissociation-point of calcium carbonate. This explanation, which I believe to be in accord with that of Sir Frederick Abel, merely brings the compounds of iron and carbon within the ordinary laws of chemistry. If, as is generally admitted with Caron, hardening carbon were more intimately combined with the iron than is cement carbon, the absorption of heat would prove the existence of carbide of iron stable at high temperatures. It would then be included within the class of explosive substances, and recalescence would not be, as it is, a reversible phenomenon. The *direct* combination of free iron with free carbon may appear somewhat paradoxical; but, in the state of hardening carbon, and at high temperatures, carbon is very different from the carbon in polymeric compounds with which we are accustomed to deal at ordinary temperatures. In this form it possesses a particular

Digitized by Google

chemical activity, which enables it to combine *directly* not only with iron, but also with hydrogen and nitrogen. (Forquignon's experiments, *Annales de Chimie et de Physique*, 5th Series, Vol. XXIII.) It should be noted that the station a_{r1}, which increases from the extra mild steel up to the hardest steel, diminishes, on the other hand, on passing from hard steel to white pig iron. It follows, therefore, that in the latter the greatest portion of the carbon remains in the same state before and after recalescence. Is it hardening carbon that exists in the cooled pig iron, or does the cement carbon remain combined at a red heat? The latter alternative is the true one. This is proved by the experiments of my friend M. Werth, who has found that the residue, isolated by Weyl's method from the identical white pig iron employed in my researches, contained but a minute proportion of iron—that is to say, of iron carbide. Besides this, a portion of the hardening carbon easily assumes the form of graphite in very pure and highly carburised pig irons. To effect this, it is merely necessary to heat the white pig iron slightly above its melting point, and to allow it to cool slowly. Even in steel, carbon never assumes one of its two forms, hardening carbon or carbide carbon, to the complete exclusion of the other. This may depend on the fact that the rate of cooling is never infinitely rapid nor infinitely slow, and also on the nature of the medium in which the reactions are effected. In fact, it is assumed that in a solid, where the molecular movements are very limited, all the atoms of carbon are not able to reach the atoms of iron necessary to combine with them. The temperature at which this combination is effected tends to slowly rise, under the conditions employed in my experiments, in proportion to the increase in the amount of carbon contained in the metal. The position of the maximum of a_{r1} is as follows:—

1. Electrolytic iron	660°
2. Extra mild steel	662–655°
3. Mild steel	660°
4. Medium steel	661°
5. Hard steel	674°
6. White pig iron	695°

The two samples 3 and 4 containing a little more manganese than the rest, the point a_{r1} is comparatively a little lower, as will subsequently be seen. It is, however, probable that the temperature of combination is theoretically constant; but the reaction is retarded in practice by the comparative scarcity of the carbon.

Let us now examine the critical points of iron. In electrolytic iron, during cooling, two abnormal evolutions of heat occur. One, a_{r3}, commences and ends abruptly, and causes at 855° C. a fairly prolonged stay of the thermometer; the other, a_{r2}, is less distinct, and has no precise limits. It extends from about 750° C. to 690° C., passing through two unequal maxima. The same critical points are found in extra-mild steel; a_{r2} preserves its position and character, but the station a_{r3} is converted into a gradual slackening between about 845° and 800° C., with a maximum at about 820°C. In mild steel a_{r3} is still lower, and becomes confounded with a_{r2} into a single gradual slackening, $a_{r(3\text{-}2)}$. It is easy to show, by measuring the areas of the bulges in the curves, that the quantity of heat liberated at $a_{r(3\text{-}2)}$ by mild steel is practically equal to the sum of the quantities of heat $a_{r3} + a_{r2}$ liberated at two points by the preceding sample. In medium steel, the double point $a_{r(3\text{-}2)}$ continues to descend. Its maximum, between 700° C. and 690° C., is still distinctly separated from a_{r1}, but the end of the arrestation coincides with recalescence. Lastly, in hard steel, all the critical points are united into a single one, $a_{r(3\text{-}2\text{-}1)}$ at 674° C.

To sum up, in proportion to the increase in the amount of carbon, a_{r3} is rapidly lowered (excepting occasionally a small residue which remains in the original position) and first joins a_{r2}; then the double point $a_{r(3\text{-}2)}$ descends in its turn, and finally coincides with a_{r1}. The superimposed curves in Fig. 5 clearly show this progress of the phenomena. Since the point a_{r3} is the more individualised the nearer the iron approaches to purity, it is evident that this point corresponds with a molecular modification of iron. *Iron is a polymorphous element*, like sulphur, silicon, &c. In the present state of our knowledge, it is difficult to say whether a_{r2} is a second distinct molecular modification of a_{r3}, or whether it is simply the end of a_{r3} retarded by the presence of a little carbon. In support of the second opinion, which appears to me the more probable, it may be urged:—1. That the best-known molecular changes are effected at a well-defined temperature, which is not the case with a_{r2}. 2. That as the presence of a sufficient quantity of carbon causes a_{r3} to descend as a whole, it is natural that a slighter quantity of carbon partially produces the same effect. 3. That carbon is not uniformly distributed throughout the mass of the metal, and that a very mild steel may be considered as a mixture of pure iron and harder steel. 4. That the curve of the thermo-electric powers of iron, compared with that of carbon, does not exhibit any distinctly marked point at a_2 ("Transformations du Fer et du Carbone," by F. Osmond). None of these arguments, however, is decisive, and it is merely *probable* that a_{r2} is the retarded end of a_{r3}. I therefore accept this view provisionally and until it is disproved, and shall assert that iron below a_{r2} possesses the molecular form α, and assumes above a_{r2} the allotropic form β. Between a_{r2} and a_{r3}, when these two points are distinct, the metal is a mixture of the two varieties α and β.

The action of carbon on iron in steels and white pig irons may now be summarised in a few words. Carbon, in the state of hardening carbon, maintains iron in the β condition, during slow cooling, up to a temperature which is in inverse proportion to the amount of carbon contained in the metal.

It is evident that the sudden variations observed by different investigators in the physical properties of iron and steel may be referred to one of the points a_1, a_2, or a_3. The following are a few selected examples:—1. Gore's phenomenon and Barrett's recalescence are at once identified with a_{r1}, or more generally with the triple point $a_{r\,3\text{-}2\text{-}1}$. 2. Pionchon, in his researches on specific heat, found the two points a_{r2} and a_{r3} in commercial iron and in iron reduced by hydrogen; but he placed his point a_3 between 1,000° and 1,050°—that is to say, at a temperature a little too high. 3. Hopkinson's experiments on the magnetic properties of iron and steel identify, in a highly satisfactory manner, the appearance and disappearance of magnetism with the point a_3 if it is isolated, and with the multiple point containing a_3 if the latter is not independent. 4. Le Chatelier has shown the coincidence of a_3 with the abrupt variation occurring in the law of the dilatations of soft iron. 5. The same observer found two remarkable points in the curves expressing the electrical resistance of steels as a function of the temperature. One of these points corresponds to a_3, and the second appears to refer to a_1. 6. I myself have found, on repeating Tait's experiments on my samples, that the thermo-electric power of iron passes through a singular point at a_3 for soft iron, and at $a_{3\text{-}2\text{-}1}$ for hard steel. It is thus evident that the greater number of the experiments made before or after mine are in accord with them. If, among the observations published, there are any others that appear to be discordant, it may be hoped that all difficulties will soon disappear, either when the numerous causes capable of displacing the critical points are better known, or when the temperatures have been determined by processes that admit of comparison.

THE CRITICAL POINTS OF IRON AND STEEL.

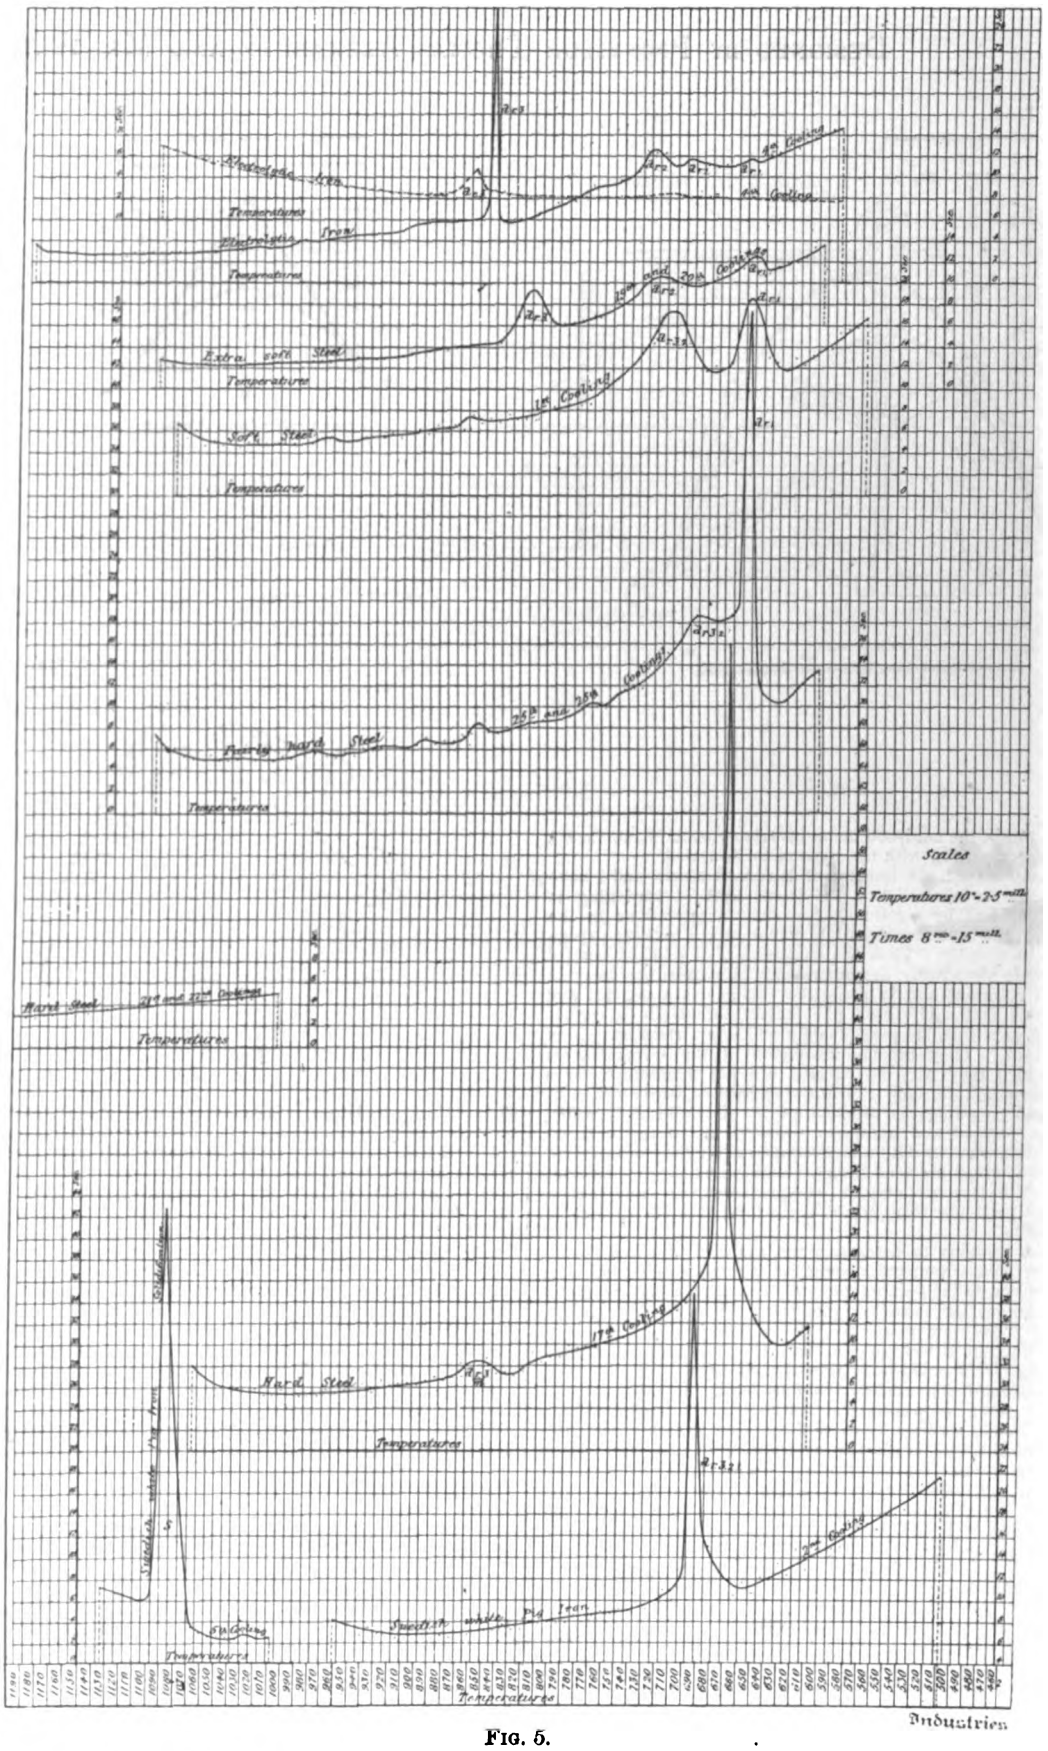

FIG. 5.

(B) INFLUENCE OF THE INITIAL TEMPERATURE AND OF THE RATE OF COOLING ON THE POSITION OF THE CRITICAL PERIODS. THEORY OF HARDENING.—If the same samples are submitted to a series of successive heatings and coolings in which the maximum temperature of heating is gradually increased, it is found that the recalescence is lowered, fairly rapidly at first, then very slowly when the cooling starts from a higher initial temperature. The position of recalescence is similarly lowered when the cooling is accelerated, as is shown in Table II., page 482.

During the hardening in water, an arrest in the fall of temperature is no longer noticed. Thus, when the rate of cooling is fairly considerable, the changes produced during slow cooling are not produced, at least integrally. Hardened steel is a steel in which the iron and carbon have preserved more or less completely in the cold the condition which they possessed at high temperatures. The heat of the change that has not been effected remains disposable in the metal, and may be termed the latent heat of hardening.

As it is difficult to observe, during cooling in water, an even comparatively lengthy arrestation of the thermometer, the preceding conclusions might appear very slight. They are, however, confirmed by two other methods.

1. I dissolved in equal volumes (500 cubic centimetres) of a saturated solution of the double chloride of copper and ammonium, equal weights (1·5 gramme) of different steels, successively annealed and hardened, and I measured the quantity of heat liberated in each case by the reaction ($2\,CuCl_2 + Fe = 2\,CuCl + FeCl_2$). The rises in temperature, after all corrections were made, were found to be as follows:—

	Annealed.	Hardened.
Medium steel	2·866° C.	2·477° C.
Hard steel	2·148° C.	2·309° C.
White pig iron	1·665° C.	1·678° C.

A BENDING MOMENT DELINEATOR.

DESIGNED BY PROFESSOR THOMAS ALEXANDER AND MR. ARTHUR W. THOMSON, GLASGOW.

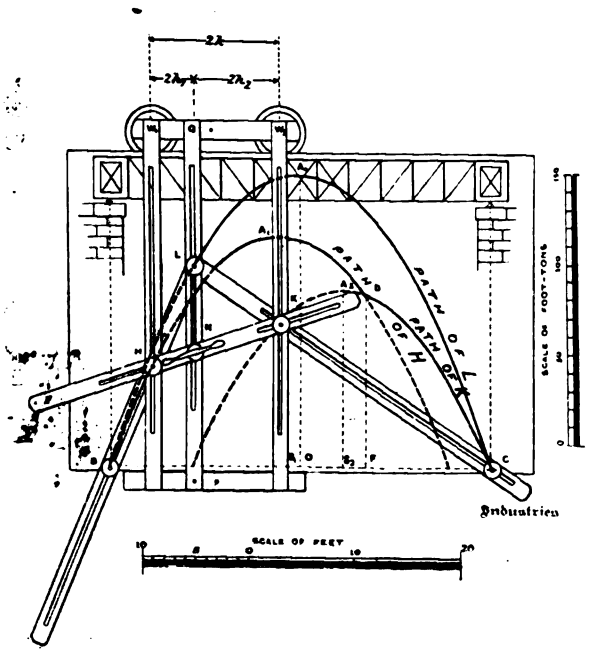

FIG. 1.

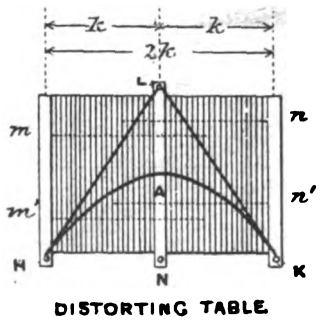

FIG. 2.

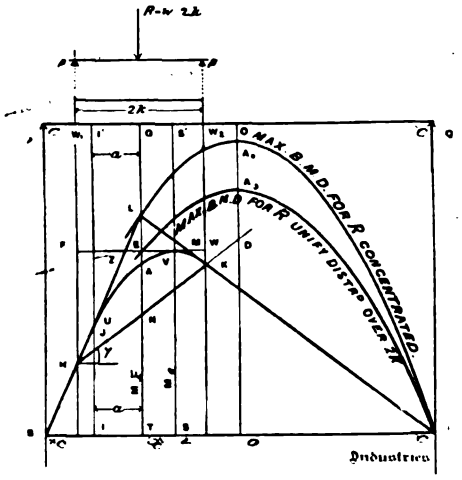

FIG. 3.

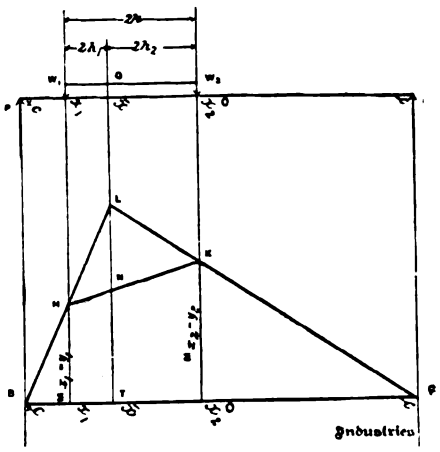

FIG. 4.

In other words, the hardened metal invariably contains an excess of heat in comparison with the same metal annealed.

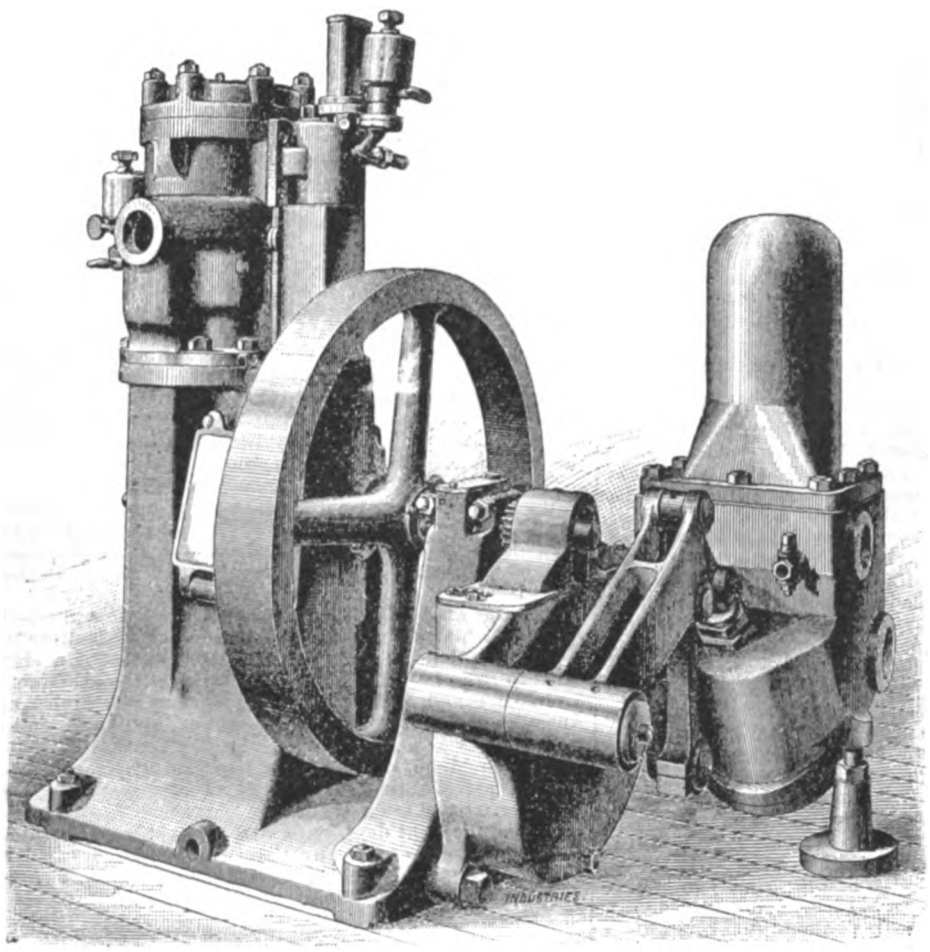
2. I have traced the heating of hardened steels, and I have shown that the liberation of the latent heat of hardening is rendered evident by certain characteristic accelerations in the progress of the heating. I shall, however, return to these experiments subsequently. Thus the existence of the latent heat of hardening is abundantly demonstrated. Moreover, the delay in chemical reactions and in molecular changes is a general and well-known fact. All these phenomena necessitate a certain time, and, as a rule, are possible only within a certain interval of temperature. They become incomplete if the circumstances under which they may be effected are not maintained for a sufficient length of time. In this way Sainte-Claire Deville, by very rapidly cooling the products of the dissociation of water, kept the oxygen and hydrogen separate up to the ordinary temperature, whereas with a less abrupt cooling they recombined. In this way sulphur cooled from a suitable temperature assumes the condition of plastic sulphur, and preserves, for some time at least, this particular form, which is the form of stable equilibrium above 260° C.

It now remains to determine the share of iron and that of carbon in the new properties communicated to steel by hardening. In opposition to the opinion generally accepted, I believe that it is not carbon, but the allotropic β-iron which is the principal cause of these new properties. This theory would be placed beyond doubt if it were proved that (1) a steel containing much hardening carbon could be soft; and that (2) a steel containing very little hardening carbon could be hard. In order to establish the first proposition, I hardened my medium steel (sample No. 4) between $a_{r(3\text{-}2)}$ and a_{r1}, that is to say, when the change of the iron is already well advanced, although that of the carbon has not yet commenced. Under these conditions the metal was soft under the file, and when treated with nitric acid gave the reaction for hardening carbon. This experiment, however, has been criticised, not without reason, by Mr. Howe. It is indeed possible that the steel thus hardened, although less hard than the file, had acquired a certain amount of hardness; and, on the other hand, the nitric acid reaction, as applied, is simply qualitative. I admit, therefore, that this test is not conclusive, although it appears to me to agree with those of M. Nouel, engineer of the Compagnie de Chatillon et Commentry, in his researches on dilatation. The second proposition, however, lends itself to a more satisfactory demonstration, and it is easy to prove by figures that very mild steel may be considerably hardened in the absence of notable proportions of hardening carbon. For this it is merely necessary to harden from a higher temperature at a_{r3}, and to render the cooling extremely rapid by plunging a bar of slight thickness into a freezing mixture. Under these conditions the tensile strength may increase from 42 kilogrammes per square millimetre (26·6 tons per square inch) of the original section (annealed metal) to 97 kilogrammes (61·5 tons per square inch, hardened metal), whilst the elongation decreases from 30 to 4 per cent. We have thus to deal with a steel containing 0·22 per cent. of carbon, only a small fraction of which has retained the form of hardening carbon. It follows that the hardening carbon is not responsible for the enormous diminution in the malleability that has just been shown. Moreover, electrolytic iron clearly shows that iron, in the absence of carbon, may acquire the hardness of hardened steel. I conclude that *hardened steel owes its properties principally to the presence of β-iron*, which is hard and brittle by itself at the ordinary temperature. The influence of carbon is of the same character as that of the rate of cooling, and both combine to produce the final result. The rate of cooling alone is not sufficient under the ordinary conditions in which hardening is effected to maintain an appreciable fraction of the iron in the β-condition. But as, under the same conditions, it is easy to maintain the carbon in the state of hardening carbon, and as the hardening carbon imparts stability to β-iron, it is evident in what manner β-iron may be successfully preserved up to the ordinary temperature by the aid of carbon. The more rapid the cooling the more incomplete are the changes and the harder is the hardened metal.

(C) PHENOMENA OBSERVED ON HEATING THE SAME SAMPLES BETWEEN 600° C. AND 1,100° C.—I append a comparative table (Table III., page 482) of the critical points in cooling and heating. I may, however, remark, that the determination of these critical points is not as sure during heating as during cooling on account of the irregularities in the pressure of gas and of water that supplies the blast. It is thus evident that all the critical points studied are reversible, as might have been expected, since they are reproduced identically by a series of successive coolings of the same sample. a_2 alone is situated in the same interval of temperatures on heating as on cooling. For the other critical points, their temperature is higher during heating than during cooling. It is true that the temperature of steel rods when heated or cooled is never quite the same at the surface and in the interior, whence it follows that the temperatures indicated by the couple are somewhat low during the cooling, and somewhat high during the heating. But the normal error which results from this fact is very much smaller than that which is observed in the majority of cases, and which has been also noted by other authors (Norris, Brinell, Newall, &c.). It is probable, however, that the theoretical temperature of the critical points should be the same in both cases; but as the chemical reactions, as well as the dimorphous changes, acquire a certain velocity only when the system is sufficiently distant from its conditions of equilibrium, it is constantly found in practice in the shape of more or less lengthy delays due to the rate of heating and of cooling. In the special case of steels, these delays may still be exaggerated for the combination of iron with carbon, by the solid condition of the medium, and for the change of the iron by the presence of carbon. The loss between a_{r3} and a_{c3} is at a minimum for electrolytic iron. These experiments confirm and explain an important fact observed by Brinell, namely, that the temperature to which a steel must be heated to enable it to acquire hardness, and that at which it suffices to plunge it into water for hardening it during its cooling, are not identical.

(D) HEATING AND COOLING BELOW 600° C. THEORY OF TEMPERING.—Iron and steel previously annealed do not present critical points in this region. This is, however, not the case with hardened steel. It is known that hardened steel, reheated at increasing temperatures, loses by degrees the hardness and brittleness imparted to it by hardening. From this it may be concluded that the latent heat of hardening is liberated during tempering, and should produce characteristic accelerations in the rate of heating. These suppositions are completely confirmed by experiment. Fig. 4, page 482, shows a comparison of the curves of reheating of the same steel annealed and hardened. The liberation of the heat of hardening begins to be exhibited at about 200° C. under the conditions of the test; it presents its maximum at about 350° C., and appears to cease at about 520° C. A final liberation of heat is exhibited between 660° and 680° C., quite near to the station marked $a_{c(3\text{-}2\text{-}1)}$. Hence, it follows that iron and carbon which in hardened steel were not in equilibrium, just like plastic sulphur, tend to resume, as far as circumstances will allow them, their state of equilibrium, which is normal at the temperature under consideration. Thus, *during tempering, the β-iron returns to the α-condition, and the hardening carbon to the condition of iron carbide.* In the present state of our knowledge, however, it is not yet known whether the changes of iron and carbon are successive or simultaneous, nor is it known what interpretation to give to the different accelerations observed during heating. Does the iron assume the α-condition when the hardening carbon which maintains it in the β-condition has combined with the iron? Or can the β-iron, on the other hand, left to itself, subsist up to a higher temperature? This is difficult to decide, in spite of the important researches made on tempering, notably by Barus and Strouhal. (*Bulletin of the U.S. Geological Survey*, No. 14, 1885, and No. 35, 1886; *American Journal of Science*, Vols. XXXII., December, 1886, XXXIII., January, 1887, XXXIV., July, 1887; *Washington Laboratory Bulletin*, No. 27.) These physicists have shown that, at the melting point of lead, steel previously hardened recovered, almost but not completely, the electrical resistance and thermo-electric constants of annealed steel. The melting point of lead coincides, moreover, with the maximum of acceleration observed by me during the reheating after hardening (about 350° C.). On the other hand, the specific magnetism of steel tempered at 330° C. is very different from that of the same metal annealed; and the second acceleration shown by my curve between 660° C. and 680° C. (an acceleration which is, moreover, confined to very hard steels) proves that the effects of hardening are not completely destroyed at this temperature. The question is in reality very complicated. M. Werth and myself have clearly shown, on a steel of medium hardness, that tempering in a bath of lead at about 400° brings back the carbon to the state of iron carbide as completely as annealing at redness. If, however, the chemical state was the same in the two cases, it was not so with the physiological state of the carbon. Although Weyl's method isolates the carbide from annealed steel in the form of brilliant metallic spangles, the carbide from tempered steel, with the same percentage composition, appears in the form of a dull amorphous powder. The carbide is formed *in situ*, and remains in a state of infinitely fine division. Like the hardening carbon which has produced it, it cannot, at the comparatively low temperature of 400° C., be collected into scales, as it is at a red heat. Hence there is a great difference in structure, which appears to have a considerable influence on certain physical properties, and above all, on the comparative mechanical properties of annealed steel and of tempered steel. It is a noteworthy fact that the change of the carbon is gradual. This fact is in complete accord with daily practice, which shows that the effect of tempering is proportional to the temperature attained. It is rendered evident by the shape of the curve of reheating; and Barus and Strouhal have proved that, for a given temperature, steel previously hardened tends towards a state of equilibrium which depends only on the temperature, and which is attained the more rapidly the higher this temperature is. The reaction being possible, it would appear to be complete, as any tendency to the inverse reaction does not limit it to the temperature under consideration. If this is not the case the solid nature of the medium does not permit, at the desired moment, as a liquid or gaseous medium does, the contact of all the atoms that ought to combine. Perhaps the tardy liberation of heat between 660° C. and 680° C. should be attributed to the same cause. It is evident that before the broad principles of the theory of tempering are developed, the details must be worked out. The more affirmative theory I formerly enunciated now appears to me, after much investigation and reflection, to have been premature.

(To be continued.)



A BENDING MOMENT DELINEATOR.

A SHORT time ago Professor Thos. Alexander and Mr. A. W. Thomson read a paper before the Institution of Engineers and Shipbuilders in Scotland, on their "Bending Moment Delineator, and its application to maximum bending moments due to moving loads." As this instrument has been proved to be capable of correctly indicating the bending moments in structures, we give

GAS ENGINE AND PUMP.

CONSTRUCTED BY THE NATIONAL METER COMPANY, NEW YORK, U.S.A.

GENERAL VIEW OF ENGINE AND PUMP.

VERTICAL SECTION THROUGH PUMP.

herewith a short description of it. On page 484 Fig. 1 gives a general view of the instrument, Fig. 2 shows the distorting table used in connection with it, Fig. 3 is a diagram of the curves drawn, and Fig. 4 is a skeleton outline.

It is in the form of a working model. Bending moment curves and scales are drawn on the face of the board. The frame consists of slotted vertical bars W_1, G, W_2, fixed at the top and bottom to cross pieces. The middle vertical bar can be fixed in two positions—one midway between the two outer bars, the other as in Fig. 1, nearer the left. The frame can move along the face of the board, this motion being facilitated by the use of friction rollers. The compass bars L B and L C are hinged at L, and by means of slots pass over bolts B and C. Another bolt forms the hinge L, and slides in the slot of the middle bar of the slot frame. The transverse bar H K is also slotted, and near its centre carries a handle for moving the whole arrangement into any desired position. The bar H K can rotate on a bolt N, which passes through the slot in the middle vertical bar. The bolts H and K pass through the slots of the compass bars, of the two outer vertical bars, and of the transverse bar. The distance between the two points L and N is kept constant by means of the distance piece L N, which slides in the middle vertical slot, and whose ends pass over the bolts L and N. The distorting table (Fig. 2) is composed of about 90 wooden laths, 9in. by ⅛in. by ⅛in. thick. The middle and two outer laths are heavier, as they have to guide the others and keep them in position; their ends H, K, L, N are strengthened with pieces of sheet brass, and can slip over the corresponding bolts of the slot frame, arranged so that the inner vertical bar is midway between the other two. On the under sides of laths H and K guiding pieces are fastened, which slide in the slots of the slot frame. Wires hinged at m, m^1, n, n^1 pass through small holes in the middle lath L N, and remain parallel to the centre line of the slot H N K while the table is distorted; on these wires the intermediate laths are threaded. On the face of the table, when rectangular, a parabola H A K and two tangents H L and K L are drawn. (See Fig. 3.)

When the slot frame is clamped in any position (Fig. 1) the model is rigid. For suppose the compass bar lifted off the bolts B and C, and the four points H L N K moved upwards in the slots any short distances and so as to keep the bars B L, L C parallel to their original directions; also that the points L and N are fixed in their new positions, and that the compass bars are again put over the bolts B and C; then the two points H and K must move downwards in the slots, and the line H N K will be no longer straight; but in the model H N K is a rigid bar, and therefore, for any given position of the slot frame, there can be only one triangle H L K, and it can have only one position.

As the slot frame moves across the face of the board, the points H, L, K, and N describe portions of the same parabola in different positions, as illustrated in Figs. 1 and 3. The co-ordinates of the point D, the intersection of the paths H and K, can be found, and it can be proved that, for every position of the delineator, the centre line of the transverse bar produced, if necessary, passes through the point D (see Fig. 4). Taking advantage of this latter fact, the authors have devised a modified form of the moment delineator. In this modified form the distance piece L N is no longer necessary, and may be removed; a pin is fixed into the board at the point D, and projects slightly from its face; and the transverse bar is placed next the board with its slot passing over this pin. The authors show that the locus of the tops of the maximum ordinates for the bending moments is a parabola.

The delineator is a decidedly interesting piece of apparatus, and it will have a place in engineering classrooms and laboratories.

GAS ENGINE AND PUMP.

THE accompanying illustrations show a combined gas engine and pump made by the National Meter Company, of New York. Mounted on the engine shaft is the pinion L, which engages with the wheel K. As the wheel is enclosed in a box containing oil, thorough lubrication is provided, and the wear of the only quick-moving part of the pumping portion of the machine is reduced to a minimum. The shaft of the wheel K carries a crank connected by the rod J with the rocking lever D, which, by the rod E, is connected with the rod of the plunger F. The water enters through the valve H and is discharged through the valve G. This arrangement of the several parts of the pump in relation to the engine permits of the placing of the entire machine on one base, thereby obtaining all the advantages to be derived from rigidity and compactness. It is stated that at the price for which gas is sold in New York this engine will raise 1,000 gallons of water to a height of 75ft. for 2½ cents. We are indebted to our contemporary, *The Iron Age*, for our illustration.

THE POSTAL JUBILEE.

THE Post Office is such an important institution for the promotion of industry and commerce that the jubilee anniversary of the introduction of inland uniform penny postage, which was celebrated last Friday evening in the Guildhall, as a joint affair of the Corporation of the City of London and the Post Office authorities, demands notice. Arrangements were made for the display of apparatus connected with the Post Office, and the illustration of their use, as for example the stamping, sorting, and preparation of letters, and the making up receipt, and despatch of mails. Specimens were shown of telegraphic apparatus, and communication was maintained direct from the office in the Guildhall to several Continental cities, and special arrangements were made for transmitting direct to various journals an account of the proceedings. The chief speech was delivered by Mr. Raikes, the Postmaster-General, and, after paying a graceful compliment to the memory of Sir Rowland Hill, he gave a sketch of the changes which had taken place since 1840 in consequence of the establishment of the penny post. In the year immediately preceding 1840 the number of letters delivered in the United Kingdom amounted to 76,000,000, whereas last year they amounted to 1,600,000,000, or twenty times the number of letters which passed through the post fifty years ago. In addition to the letters there were 652,000,000 postcards and other communications by the halfpenny post, and an enormous number of newspapers.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 20th May, 1890.

IRON.—The French iron markets, in spite of the weak tendencies abroad and the slack demand at home, show increasing firmness. Thus here in Paris, though consumers buy only sufficient for present needs—and those needs are small—the merchants are seeking to re-establish the price of 160s. for bars and joists. News to a similar effect comes to us from the provinces. The manufacturers of the Ardennes maintain the price of 160s. a ton for bars, and the manufacturers of the North refuse to make any concession on 156s. Seeing that the demand is nowhere brisk, this firmness must be attributed to the prospect of dear coal. This is, however, an artificially formed situation, which cannot last long. Already English iron, Middlesbrough No. 3 pig, is being offered to the forgemasters of the Champagne group at 67s. to 68s. a ton delivered in the neighbourhood of Saint-Dizier, and Belgian iron, both crude and finished, is beginning to find its way over the frontier.

METALS.—The metal market is more animated than it has been for some time past; but its renewed life proceeds from speculative operations rather than genuine business. The holders of copper warrants find it necessary to give a fillip to the market every two or three weeks to keep it up to the point desired. Consumers have, however, nothing to lose by limiting their purchases to what is strictly necessary for the moment. The recently published statistics of the stocks in hand have deceived no one. Tin is a little weaker. Lead has recovered a little; but spelter has given way a point in the course of the week.

THE BREWING INDUSTRY.—The consumption of beer in France is constantly increasing, and the brewing industry is steadily developing itself. The development is, however, not sufficiently rapid to meet the growth in the consumption of the beverage. Evidence of these facts is to be found in the statistics of production and the Customs returns for the year 1889. The production of beer last year amounted to 8,700,000 hectolitres, against 8,400,000 hectolitres in 1888. The quantity of foreign beer imported in the same time amounted to 224,321 hectolitres, against 188,306 hectolitres in the previous year. Of this quantity Germany supplied 172,736 hectolitres, England 20,539 hectolitres, Austria 766 hectolitres, and other countries 30,280 hectolitres. The imports of German beer have greatly fallen off in the last few years.

THE WOOLLEN INDUSTRY IN FRANCE.—The official report of the trade of France for 1888 allows a comparison between the volume of the woollen industry and the general movement of foreign trade. The figures are as follow:—

	Imports. Frs.	Exports. Frs.
Raw wools of all kinds	341,252,000 ...	131,284,000
Woollen yarn and goat's hair....	14,086,000 ...	37,160,000
Tissues of wool, pure and mixed	65,176,000 ...	323,375,000
Total for wool and its products	420,514,000 ...	491,819,000
Total general of merchandise ...	4,107,007,000 ...	3,246,749,000
Total of manufactured products	578,807,000 ...	1,706,583,000
Total of raw materials.....	2,021,164,000 ...	813,443,000

FRENCH SEAPORTS.—From recent statistics it appears that the order of French seaports in commercial importance and the tonnage of the vessels in each during the past year are:—Marseilles, 4,623,650 tons; Havre, 2,653,685; Bordeaux, 2,489,512; Dunkirk, 2,020,848; Rouen, 1,721,710; Cette, 980,151; St. Nazaire, 915,930; Dieppe, 517,703; Boulogne, 476,116; Bayonne, 465,788; Nantes, 374,315; Caen, 351,608; La Rochelle, 335,883; Calais, 273,706.

BERLIN, 19th May, 1890.

IRON.—The iron market here is moderately active and steady, the demand being chiefly for building iron. Silesian bars have not recovered in price, but are still quoted 205s. a ton. From Breslau the market is reported active, both for crude iron and for finished iron and steel. Grey pig finds ready purchasers at 83s. to 85s. a ton. The demand is brisk for joists and steel plates on export account. Ships' plates are being sent in large quantities to Kiel. Founders and machine makers are very busy. W. Fitzner's works at Laurahütte turned out their three-thousandth boiler last week. Since the year 1874 the number made at these works exceeds 2,000.

METALS.—The revival noticed in the metal markets report last week has made further progress. There is, however, no visible expansion in the volume of trade transacted, consumers still limiting their purchases to what is strictly necessary for the requirements of the moment; but a stronger tone prevails, and prices have risen all round. Mansfeld refined copper is quoted £60; English brands from £57 10s. to £59. Banca tin has advanced to £103. The Silesian market for spelter is steadily improving. The W.H. brand is quoted £25 to £25 10s. Clausthal refined lead is very firm at £15 to £15 10s. a ton.

COAL.—A Breslau correspondent writes: "The altered state of the coal market is becoming significantly visible in the rapid accumulation of stocks about the pits. To check this accumulation some of the colliery proprietors have resolved to work one shift a week less from the 17th of the present month. Hence it is evident that the production is not to be maintained at the high level reached in the first quarter of the year. There is no diminution of activity in the coke-making industry." The production of the Lower Silesian coal mining district in the first quarter of the current year amounted to 615,088 tons, against 591,879 tons in the corresponding portion of 1889.

THE YARN INDUSTRY.—Flax spinners have work enough in hand to keep them fully occupied for some time to come. The yarn market is somewhat less active, consumers having bought well forward, but the situation is such that prices must remain firm. The Association of German Jute Manufacturers has under consideration a proposal to further advance the prices of jute yarns and woven fabrics.

THE TEXTILE INDUSTRY OF SAXONY.—The state of the textile industry in Saxony at the present time is the subject of much complaining on the part of the manufacturers. Business is slack, and as the near prospect is without any encouraging feature many have begun to restrict production. In the Chemnitz district a considerable number of operatives are either out of employment or have gone into some other industry as labourers. Wages have dropped considerably within the last three or four months. The tapestry branch of the textile industry is the only one in which there is anything like activity. But even in that branch prices are depressed.

ELECTRICAL CONGRESS.—The Electro-Technical Society of Frankfort-on-the-Main has decided to hold an international electrical, or, more correctly, an electro-technical, congress in that city next year, during the time of the Electro-Technical Exhibition. The invitations will be issued immediately.

DEATH OF AN ELECTRICAL ENGINEER.—The death took place on the 8th inst. of Mr. Carl Fritchen, of Messrs. Siemens & Halske. He entered the service of the Hanoverian Government in 1850, and in spite of his youth was entrusted with the superintendence of the erection of railway telegraphs, and shortly afterwards he was appointed chief of the Hanoverian telegraphs. In 1856 he invented electro-magnetical duplex telegraphy simultaneously with Dr. Werner Siemens. In 1867 he entered the telegraph service of the North German Confederation. In 1870 he accepted an offer of Messrs. Siemens & Halske to enter their service as chief engineer. His inventive capacity, combined with his practical turn of mind, found full scope in the large and diversified works of the firm extending to all branches of electricity.

THE VULCAN SHIPBUILDING YARD AT STETTIN.—It has been announced that this company, which in 1888 paid a dividend of 6 per cent. on the preference and ordinary shares, will this time only pay a dividend of 5 per cent. on the preference shares, whilst the ordinary shareholders will receive nothing. In the report the explanation afforded is that only merchant vessels came into account last year, some of which were undertaken at a loss simply to provide employment for the workmen in the winter of 1888-9.

GERMAN TELEGRAPH AND TELEPHONE SYSTEMS.—A further extension in the telegraph and telephone network of the German Empire is shortly to be undertaken. Nearly 8,000,000 marks are to be devoted to the purpose in the current year. According to the plan, 3,099,500 marks will be applied to enlarging the town telephone installations and to the telephonic connection between different towns; 1,928,000 marks are provided for new telegraph offices, especially in the country; 761,900 marks will be applied to the improvement of telegraph wires, the erection of double poles, the transformation of overhead wires to underground wires; and lastly, 87,000 marks is intended for extending the pneumatic post installations in Berlin and Hamburg. The work has already been commenced at a number of points, and, as the weather is favourable, great progress is being made.

VIENNA, 19th May, 1890.

THE IRON MARKET.—The situation of the iron market does not change. The prices of bar iron, foundry goods, and sheets are kept high at the syndicate level, but there is no animation and no inclination to buy. The decrease of prices in the German markets up to the present time has not influenced the Austro-Hungarian markets, but some reserve in buying was the consequence. Bohemian sheet-makers are very busy. The Austro-Hungarian iron market for the year 1889 shows an increase of the production of pig iron of about 15 per cent., and of bar iron about 10 per cent.; the quantities of rails did not reach half the possible maximum production. A large order has been received by Messrs. Nicholson & Co., of Budapest, from the Hungarian Ministry of Communications, for two steamers with 600 h.p. triple-expansion engines and two steamers with 300 h.p. compound engines, both with a short term of delivery. Further, Messrs. Nicholson & Co. have received orders for two petroleum ships and thirty-five steam tugs.

THE COAL MARKET.—In the Austro-Hungarian coal and coke market there is still a very animated business. The amount sent away from the Bohemian districts steadily increases, and, as the traffic on the Elbe is easy at present, the export is very animated. The stability of the increase is assured, for markets for Bohemian coals are extending very much. The home consumption is a satisfactory one, as may be seen from the excellent financial state of the works in the Falkenau territory, which deliver most of their production to home customers.

THE AGRICULTURAL EXHIBITION.—Last week the Vienna Agricultural Exhibition was opened by its patron, the Emperor, in the company of all the Court and the ambassadors. Since 1867 there has been no agricultural exhibition in Vienna, and therefore great importance is attached to the present one, as it will show the progress made during the last twenty-three years in this branch of our national economy.

BRUSSELS, 20th May, 1890.

THE IRON MARKET.—The iron trade only exists with the greatest difficulty. New business is very scarce, and the buyers are trying to cut prices even below their present low level. Merchant bars may be quoted at 16fr., but 15fr. has been accepted by many. Pig iron has become weaker, and 65fr. is the basis price now. In the Liége district the outlook is particularly dark, and the buyers are all eagerly awaiting further concessions in the prices. The official figures for the export of iron and steel during the first quarter of the year show an increase in the shipments of rails and steel generally. Otherwise, with a few unimportant exceptions, there has been a general decrease, the most noticeable being in the products of rolling mills.

THE COAL MARKET.—The state of the coal market is undecided. Larger sizes and pit coal maintain their price, but there is a good deal of weakness in the smaller sorts. The price of coke is nominally 32fr. at present, though no sales are reported above 30fr. The buying is all from hand to mouth, as there is absolutely no confidence in the future. At most of the pits the coal-getting is all done on order, and there is none brought up for stocking at pit's mouth. At the meeting of coalmasters last week no anxiety was expressed as to the state of the market, for it was universally supposed that the depression was only temporary, and only caused by the want of briskness in the iron trade.

THE GLASS TRADE.—The demand for window glass this spring is better than ever before, and the strikes only prevent it from being better still. The question of the eight hours day is being discussed, and it is expected that the employés will strike in order to gain this point. In the meantime, there is no change in prices

THE CANAL TO BRUSSELS.—Some time since a grant of 4,000,000fr. was promised by the Minister of Agriculture to the municipal deputation for the construction of a ship canal to Brussels. The proposal has created considerable excitement and dissatisfaction in commercial circles at Antwerp, as it is alleged that the opening of navigation to inland towns is unnecessary in a small country like ours, which should be satisfied with one great seaport. The opinion prevails that it would have been better if the Government had reduced the port charges at Antwerp and abolished the light dues, steps which would have benefited the country more generally than the proposed canal is likely to do. The canal is estimated to cost from 12,000,000fr. to 16,000,000fr.

DÜSSELDORF, 20th May, 1890.

IRON.—Some disappointment is felt over the continued stillness of the iron market. For a time it seemed that the recent heavy reductions in price would bring about a revival of business, but consumers are still chary of entering into fresh engagements. The demand for pig iron is very slack, but nothing is offered below the syndicate maximum. The quotations are:—Ordinary spiegel pig, 102s.; Rhenish-Westphalian best forge, 78s.; Siegen forge, 80s.; Thomas pig, 68s.; Bessemer, 82s.; and foundry No. 1, 82s. a ton. The finished iron and steel market is gradually losing strength. The demand for bar iron for home consumption is very slack, and for export almost extinct. Hoops, too, are neglected. For plates there is a moderately active market, and for joists the demand is brisk. Wire is but little inquired for. The railway authorities have decided to adopt the 86lb. rail, and the prospect has infused life into the rail market. Manufacturers express, however, disappointment that the "Goliath" rail of 105lb. per yard was not chosen.

COAL.—The prices of household coal have dropped 1s. to 1s. 6d. a ton in the course of the last week. Business is now very slack in the coal market, not only for the household sorts, but for steam and metallurgical coal. Consumers are holding back in the hope of something like a collapse in prices. Such an event is, however, improbable. The colliery owners, who have sufficient orders already booked to keep them going several months to come, have agreed to reduce the production by dismissing the additional hands lately taken on rather than, to use an American expression, to allow the bottom to fall out of the market. Some interesting statistics, just published, concerning the coal mining industry of this district show that these additional hands number some 10,000. With this augmentation, amounting to 9 per cent., the output of coal was increased only about 3 per cent. Compared with the last quarter of 1889, the increase in the number of hands employed in and about the pits was 3,246; and with these additional hands and a considerably higher rate of wages the production fell off to the extent of about 300,000 tons. As all the pits have been worked full time since the beginning of the year, it is obvious that the cost of getting coal has been notably increased.

FLAG-STONES.—At a meeting of the flag-stone quarry owners in the district of Neuwied, held the other day, it was recommended, in view of the constant accumulation of stocks, to push the export trade more vigorously. With this intention it was agreed to freight collectively a vessel, and to despatch immediately a cargo of flags to England, where there is a prospect of some trade being done in them.

Digitized by Google

LILLE, 20th May, 1890.

Iron.—The situation seems to have improved in the course of the last week. There is no increase of business, and consumers appear to be as reluctant as ever to enter into fresh engagements, but the manufacturers have expressed themselves satisfied, and have assumed a firmer attitude in the matter of prices. At a general meeting of the Northern group, held the other day, it was shown that all the members had work enough in hand to keep them going at least two months longer. What, however, is equally true is that the fresh orders coming to hand are far from sufficient to keep things going. If the present situation is satisfactory, the near future leaves much to be desired.

Textile Manufactures.—The current of business in linen goods is a little more brisk this week, and the volume compares very favourably with that of the average for this time of the year. Orders continue to be received in sufficient abundance, and the prospect is encouraging. From Roubaix business is reported dull—paralysed, in fact, by the recent senseless strike. A good deal of the trade for the time being has been driven to Germany. A very unfavourable report concerning the tulle industry at Calais has come to hand. From this it appears that the trade in tulle is practically at a standstill in that locality, and that the near prospect offers no cheering feature.

Flax and Yarns.—The flax market continues active. Walloons are scarce and dearer. Russian flax has been less largely dealt in. Tows are not so much inquired for. For linen yarns the market is active. The demand is equal to the supply and stocks in hand are small. Prices, consequently, remain firm. Jute yarns sell readily at full prices. In the markets of Belgium the demand has slackened somewhat of late.

Rail-testing Apparatus.—Some very interesting experiments have recently been made at the Northern Railway Company's depôt at Ermont with the electro-mechanical apparatus called the "schiscophone," the invention of Captain de Place, for testing the soundness of rails. This apparatus consists of a microphone and telephone combined with a mechanical "striker" and an induction audiometer. It is said that the instrument may be relied on to reveal any latent defect in the metal, and certainly the experiments made at Ermont go far to prove the statement. Wherever a fault was indicated the rail was broken, and invariably the fault was found to exist. The Minister of Marine sent an engineer to be present at these experiments with a view to ascertain whether the instrument could be effectively applied to the detection of defects in screw shafts.

AMSTERDAM, 19th May, 1890.

Steam Communication with Mexico.—The Consul-General of Holland in Mexico has addressed a report to the Minister of Foreign Affairs, drawing his Excellency's attention to the advantages of a new and direct line of steamers between a Dutch port and a Mexican one. When established, the Consul-General thinks the existing English service of steamboats (Liverpool to Galveston, for Mexico) will not be able to compete with it. The English company, he admits, is moderate in its freights, but its service is bad, because so irregular. Moreover, goods get damaged or lost very often between Galveston and Mexico, and experience shows that the senders are without a remedy, as their complaints are disregarded or ignored. It is for this reason that importers prefer the Vera Cruz service, albeit much more expensive than the Galveston route. The Dutch Consul-General thinks that a line of steamers between Rotterdam or Antwerp and Tampico, *viâ* Cuba and New Orleans, would probably show good results. Such a line would command a large export trade, not only from Holland and Belgium, but also from Germany, Austria, and Italy. The Consul-General believes in the future of Tampico. As a competitor with Vera Cruz it is rapidly rising. The new railway to St. Louis Potosi, is completed, and it will open up a new district; whilst the Mexican Government is anxious to improve the harbour accommodation of Tampico, whose situation is much more favourable than that of Vera Cruz.

The Deli Railway.—This railway in Sumatra, which chiefly serves the rich tobacco lands in Deli and Langkat, where several English companies are also at work, has made a net profit of 246,935 guilders in the past year, and an 8 per cent. dividend will be paid. The number of passengers transported was 743,619, and the aggregate of goods forwarded amounted to 123,339 tons. The cost of working was 44 per cent., against 47 per cent. in 1888. The company is constructing several new branch lines.

Dutch Trade in Africa.—The report of the African Company at Rotterdam, the oldest and the largest European trading company on the Congo, shows that 1889 was a prosperous year. The total net profit reached 400,000 guilders, allowing of a distribution of 13 per cent. on the share capital.

The Reafforestation of the Dunes.—The Dutch Government is examining the very interesting question as to whether trees can be made to grow on the sand hills or dunes of the West Coast, thus increasing their resisting power by preventing the wind continually blowing away the sand. At present nothing will grow upon these dunes but a kind of thin long grass, which affords very little protection against strong winds.

United States Geological Survey.—The United States Geological Survey is asking Congress for an appropriation of $800,000 for the ensuing year. Nearly all of this is to be used in surveys for irrigation purposes, the average being about $40,000 for each of the far Western States, except California and Texas, for which $60,000 is asked for each. The maps for the surveys of 1888, for Montana, Colorado, New Mexico, Idaho, Utah, Arizona, Nevada, and California, will be ready for the engravers by the 1st of July. They will cost $50,000.

Petroleum in the Dutch East Indies.—The prospectus of an important new company has made its appearance. It is that of the Royal Netherland Company for the Working of Petroleum Wells in Insuland, established with a capital of 1,300,000 guilders, or a little more than £100,000. Petroleum wells have been discovered, after much prospecting, in Sumatra, and this company has been formed to acquire the concession obtained by the civil engineer, Mr. A. J. Zylker, from the Ameer of Langkat (Eastern Sumatra). The new petroleum field measures about one hundred square miles, and the concession is a monopoly during seventy-five years from 1883, within the dominions of the Ameer, who is a vassal of Holland. The concessionaire is to pay no dues whatever, but the Ameer will levy a royalty of 3d. a hundred litres of exported crude petroleum, and of 6d. a hundred litres of refined petroleum, which royalty cannot, however, exceed 5,475 guilders a year. The borings in this territory have already given very good results. Petroleum is found in large quantities and of good quality at a depth of 120 metres. It is proposed to export it, in the first instance, to Singapore and Penang; afterwards to British India, in competition with Russian. Samples will be sent to London, where, no doubt, much interest will be felt for these efforts to open up a large petroleum field in a part of the world where its existence was probably least expected. The Dutch-Indian Government mining engineers have reported very encouragingly on these new wells.

COPENHAGEN, 17th May, 1890.

The Swedish-Norwegian Railway Company.—Both the Chambers of the Swedish Parliament have, with large majorities, voted in favour of the proposed grant of 7,000,000kr. for the purchase by the State of this railway. One would therefore imagine that the transfer could soon be effected; the sooner the purchase is concluded the better. The company is constantly getting into fresh trouble, and a couple of new summonses have now been brought against it in Sweden. One is for interest on debentures due on the 15th of July last year and on the 15th of January this year. The other summons is by a labourer for damages on account of injuries received while in the service of the company.

The Viksuas Copper Works.—These works are to be discontinued; and the hands have all received notice to leave on the 1st of August. Since this notice has been given the best pit in the mines has fallen in, and it is now feared that the working will be stopped at an earlier date. The works have existed for about twenty-five years, and the number of hands employed at present amounts to about four hundred, but it has been considerably larger in former years. The production once reached 48,000 tons, but of late years it has only been about 30,000 tons of ore annually.

Fishing in Norway.—The Finmark fishing is not so good this year as last. Up to the middle of May there were caught 8,745,500 fish, of which 5,771,800 have been hung for drying. For the same period last year the quantity was 12,600,000 fish. This year's yield of liver amounts to 25,791 hectolitres, and of cod liver oil 939 hectolitres. Prices have been advancing of late.

The Telephone in Iceland.—The telephone has found its way to Iceland. A merchant at Isafjord has had one installed, and it is proposed to connect Reykjavik and Havulfjord with the telephone. It has several times been on the *tapis* to bring Iceland in telegraphic communication with the outer world, but the plan has never been realised.

Strikes in Denmark.—A very serious strike has broken out in Copenhagen, all the bricklayers having struck for nine hours instead of ten, and a minimum pay of 6¾d. per hour. Their average pay for piecework, which is almost the only mode used, is considerably in excess of this demand, so the struggle refers really to the hours. On account of the strike some 2,500 men are out of work. The struggle is likely to be a long one, as both the masters and the men are determined not to give in.

Wood Pulp in Norway.—The Norwegian wood pulp manufactories are not doing particularly well at present, and the prices on the principal markets are very low. In consequence, the rate of production is being reduced.

MADRID, 19th May, 1890.

Labour Troubles.—The labour question has begun to show very disagreeable signs in this country. At the Bilbao mining district about 6,000 men have struck work for shorter hours and higher pay. They came from the iron works to the San Francisco works and the shipbuilding yard, and made the workmen there join them. Thus reinforced, they went to the establishment of La Vizcaya, where they attempted to stop the works, but were prevented by the civil guard. Several shots were fired in order to disperse the mob, and several workmen were killed or wounded. There is also a strike of the coal miners of Asturias, who claim higher wages. It must be admitted that they have really some reason to complain, as their pay is very small indeed. Their situation is peculiar. Most of the men work in mines quite near to their homes, and they cultivate the land for themselves in addition to mining. They are comparatively independent as a class, as they do not depend entirely upon the mines for their living. It is probable that the managers of the mines will have to yield this time, and prepare to use more machinery and fewer hands for the future. The workmen of the coal district of Belmez are also on strike. But little sympathy can be shown to the companies. They sell their coal at extravagant prices, and pay as little as they can to the men.

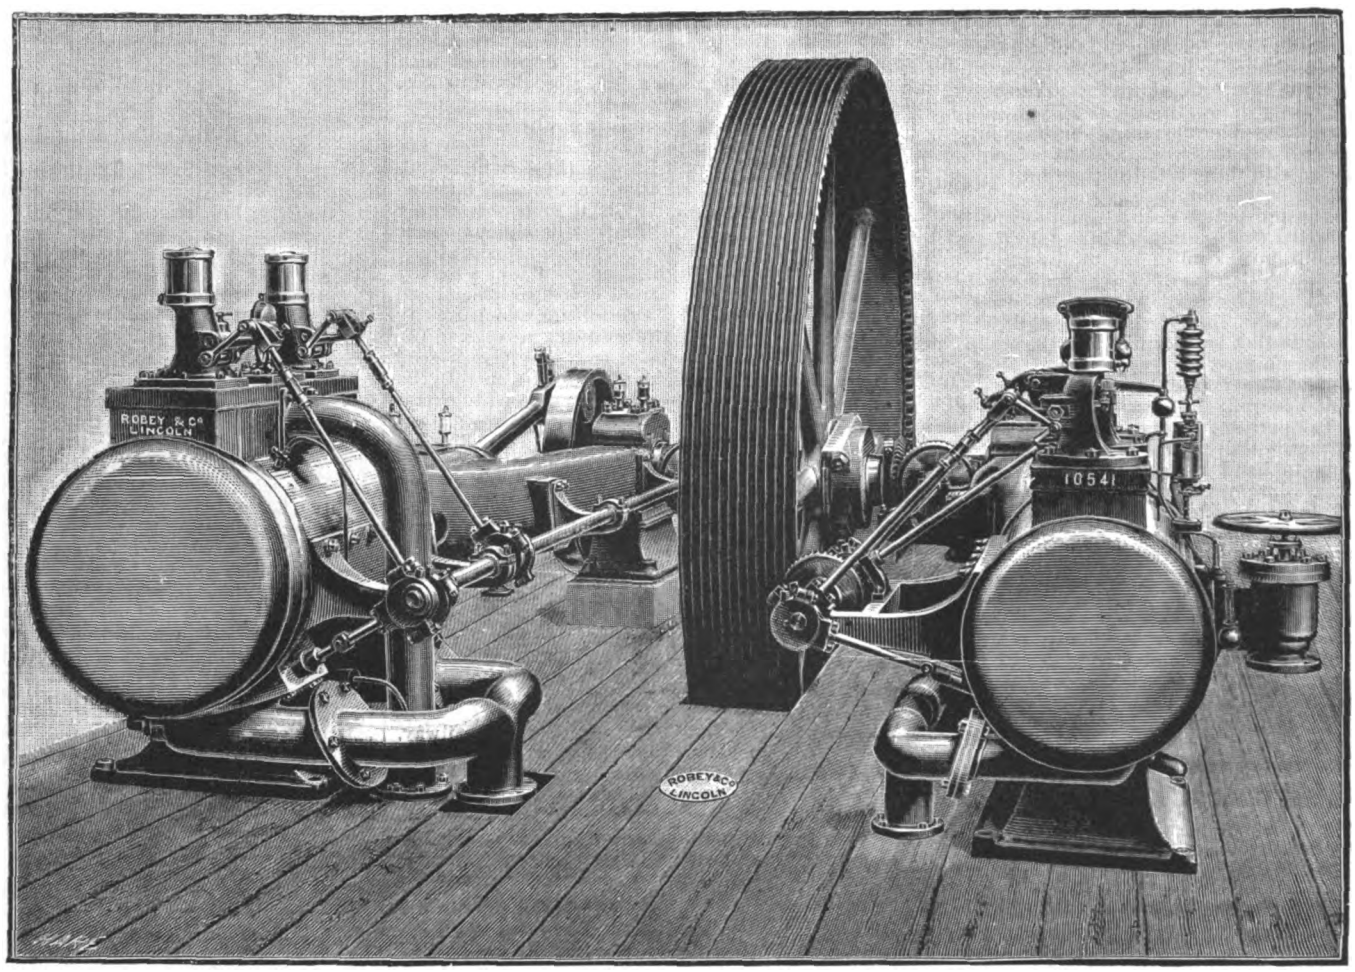
NEW YORK, 10th May, 1890.

The Iron and Steel Trades.—The desire to secure more business has been so great that it is hard to even maintain the low prices now ruling. While the trade is still confidently expecting better times, there is nothing to show that the expected improvement is near at hand. In pig iron the market is very dull. Prices are slightly better than they were a month ago, and there are indications that the lowest point has probably been passed. The supply of iron is abundant, and it will require a very heavy consumption to raise the prices to what they were at the beginning of the year.

The Coal Market.—There has been no further improvement in the anthracite trade. While there has been an increase in manufacturing sizes, it was not as great as was expected, and this is now offset by a decrease in domestic sales. Business is almost at a standstill.

The Labour Situation.—The strikes among the labouring classes are slowly extending. The numbers on strike are not very large in any one city, but they are spread over the entire country. There are now about 12,000 carpenters out, Chicago leading the list with 3,000, New York city having 2,500, and Philadelphia 1,650. Of these nearly 11,000 ask a reduction in hours, and 8,000 an increase in pay. The number of mill hands on strike is about 5,000, all of whom want a reduction in hours. There are about 7,500 iron workers and others in addition to the above, one-half asking for higher wages and about two-thirds asking for fewer hours. This number is constantly increasing, and in many cases the strikers have been successful and are returning to work.

Subsidising Mail Steamers.—The Frye Bill to provide for ocean mail services between the United States and foreign ports is about ready to be reported back to the Senate from committee. It provides for a ten year contract with American-built vessels owned and officered and partly manned by Americans. The steamers are to be divided into four classes, 8,000 ton gross register, and 20 knots an hour between the United States and Great Britain; 5,000 tons, and 16 knots; 2,500 tons, and 14 knots; and 1,500 tons, and 12 knots. Those of the first three classes are to be easily converted into auxiliary cruisers.



The "Cushing."—The new torpedo boat "Cushing" ran between Newport and New York in 6 hours and 57 minutes, an average of 19¼ knots per hour for the whole distance. She did this with hard coal, an inexperienced crew, and in the face of a brisk breeze and a choppy sea. On her trial run two months ago she made 22½ knots for three hours, and her commander says he has seen the boat travel at the rate of 24·32 knots, or 28 miles per hour. The "Cushing" is 138ft. long, 15ft. beam, 10ft. deep, and with 10 tons of coal aboard her displacement is 117 tons. She can carry 39 tons of coal, and with this can steam 4,000 miles at 10 knots per hour. The "Cushing" has also made the run from New York to Washington in 28¼ hours, with an average speed of 15 knots per hour.

Gold and Silver Production.—The gold production of the United States was 1,587,000oz. of the value of $32,800,000, against $33,000,000 in the preceding year. Of this $31,959,047 was deposited at the mints for coinage and manufacture into bars. The silver product for the year 1889 was approximately 50,000,000oz., of the commercial value of $46,750,000, and of the coinage value of $64,646,464, against an estimated product for the year 1888 of 45,783,632 fine ounces, of the commercial value of $43,020,000, and of the coinage value of $59,195,000. In addition to the silver product of our mines, about 7,000,000oz. of silver were extracted from lead ores imported into the United States and smelted in this country, and over 5,000,000oz. from base silver bars imported, principally from Mexico, making the total product of our mines, smelters, and refineries, about 62,000,000 fine ounces of silver. Of this amount the Government purchased for coinage 27,125,357oz.; there were used in the arts about 6,000,000oz.; there were exported to Hong Kong, Japan, and the East Indies about 9,000,000oz.; and there were shipped to London for sale about 20,000,000oz. Colorado still maintains first rank among producing States with an aggregate product of gold and silver of over $24,000,000. Montana stands next with a product of $22,894,000. California produced $14,034,000, of which $13,000,000 were gold, being about two-fifths of the total gold product of the United States. Utah shows a largely increased product, notably in silver. Idaho and New Mexico report an increased product, and Arizona and Nevada a reduced product for 1889. The gold product of Dakota (South) increased from $2,600,000 in 1888 to $2,900,000 in 1889. Oregon and Washington both report increased products, the former having produced $1,200,000 in gold. The States of the Appalachian range show a slightly increased product of gold over 1888.

THE EDINBURGH EXHIBITION.

MESSRS. ROBEY'S 400 I.H.P. COMPOUND ENGINE AS USED FOR ELECTRIC LIGHTING PURPOSES.

THE EDINBURGH EXHIBITION.

PRIME MOVERS.—I.

THE prime movers in the Edinburgh Exhibition may for convenience be divided into two categories—(1) those employed for electrical and (2) those employed for mechanical purposes generally—otherwise than locomotives. The leading railway companies have enriched the Exhibition by sending a number of locomotives, some of antiquarian interest merely, and others up to the most recent practice in this department, and the importance of these exhibits demands treatment apart from other examples of engine exhibits. The department of marine engineering is very sparsely represented, though the models which have been sent are of much interest.

The largest exhibit of steam engines is that of Messrs. Robey & Co., of Lincoln. The plant put down by Messrs. Robey, entirely for electric lighting, consists of nine separate engines, two of these being of coupled sets, developing in all upwards of 1,000 i.h.p. The most important is an 80 h.p. nominal coupled compound horizontal fixed engine, shown above. This engine is fitted with Richardson & Rowland's patent automatic trip expansion gear. The cylinders are both steam jacketed, and are respectively 18¼in. and 30in diameter, the stroke being 40in. The trip valve gear is fitted to each cylinder. The cut-off on the high-pressure cylinder is capable of being varied from 0 to ¾th of the stroke, and the cut-off on the low-pressure cylinder can be altered by hand without stopping the engine. The working pressure is 100lb. per square inch. The normal speed is sixty-five revolutions per minute. The driving in this case is done by rope gearing, twelve 1¾in. ropes being used on a fly-wheel 15ft. diameter. The maximum indicated horse-power is 400. The steam inlet and exhaust valves on each of the cylinders are independent. On the high-pressure cylinders double-beat Cornish equilibrium inlet valves are fitted on each end of the cylinders with the object of minimising the length of the steam passages, in order to maintain an initial pressure in the engine approximating, as nearly as possible, to that of the boiler. The exhaust valves are a special arrangement of slide-valve, giving a rapid and ample opening to the exhaust with a minimum of travel.

The exhaust valves are placed under the cylinders in order that the interior may be properly drained, and they are worked by eccentrics upon the same shaft which works the steam inlet valve gear. The engine frames are of an exceedingly substantial character, and these, like all the other parts of the engine, are excellently finished. The bearings are well lined with Babbitt metal, and are made in three adjustable parts, and fitted with lubricators. The peculiarity of this type of engine, of which Messrs. Robey & Co. are the sole makers, lies in the appliance for treating the steam after it leaves the high-pressure cylinder and before it enters the low-pressure cylinder. On its passage from one cylinder to the other the steam enters a receiver, where it is superheated by high-pressure steam from the boiler. The superheating steam circulates through a coil of tubing placed inside the receiver, which is externally lagged with wood and sheet iron. This arrangement secures that the steam enters the low-pressure cylinder at a higher temperature and drier than would otherwise be the case. The trip expansion gear is adapted both to single and coupled non-condensing and condensing engines. The makers claim that in the case of condensing engines the consumption of steam can be reduced by means of this gear to 15lb. per horse-power per hour. The above engine, while driving six Brush dynamos, each supplying current to 35 arc lamps, develops 400 i.h.p. The engine next in size is a 65 h.p nominal horizontal fixed engine capable of indicating 320 h.p. This engine is also fitted with Richardson & Rowland's patent automatic trip expansion gear and special slide exhaust valves, the low-pressure cylinder being, however, fitted with an ordinary rectangular slide having a variable travel. The diameters of the cylinders are 15in. and 26in. respectively; the stroke is 28in. The working speed is 86 revolutions per minute. The driving gear consists of nine 1¼in. ropes, which are carried on a 12ft. fly-wheel. The cylinders are jacketed as in the engine formerly described; the working pressure is 100lb. per square inch. The crankshaft is made of forged steel, and is carried by three bearings cast on the engine-bed, and a fourth bearing beyond the fly-wheel which overhangs the bed-plate. The bearings are lined with Babbitt metal. Six 35-light Brush dynamos are supplied with power by this engine.

The third engine is a 25 h.p. nominal compound "Robey" horizontal fixed engine. This engine is fitted with automatic valve gear of the slot link, block, and radius rod type, controlled by a Richardson patent spring governor. In this arrangement the cut-off valve of the high-pressure cylinder is part of an automatic expansion gear, by means of which the cut-off can be regulated from ⅛th to ⅝th of the stroke, the variations in speed being very slight. The diameters of the cylinders are respectively 9½in. and 16½in., the speed being 143 revolutions per minute. Like the second engine, the end of the crank-shaft is carried on an outer bearing. This engine is employed for incandescent lighting, its load being one of Messrs. King, Brown, & Co.'s 350-light incandescent dynamos. The fourth item in Messrs. Robey's extensive installation is a pair of coupled non-condensing vertical engines, cylinders 9½in. diameter, 12in. stroke. Here, also, the slot link automatic valve gear just described is fitted. The fly-wheel is keyed upon the crank-shaft between the two engines; the speed is 155 revolutions per minute. The fifth item is a high-speed compound engine specially designed for driving dynamos either from the fly-wheel or by being coupled to them direct. The speed is 300 revolutions per minute. The moving parts of the engine are kept as few in number as possible, the piston and rod, for example, being in one piece. The bearings are of gun-metal. The working parts are all protected by hinged cones, which prevent alike injury to the bearings from grit falling from the surroundings and injury to the surroundings from the scattering of oil by the engine. Lubrication is effected entirely inside the protecting cone, a licker on the end of the connecting-rod taking up oil at each stroke and lubricating the whole of the moving parts by throwing the oil upon them. The oil finds its way back to the well by means of a channel, and thus a continuous circulation of oil is maintained. The high-pressure cylinder valve is of the piston type. These engines are similar to those exhibited by Messrs. Robey & Co. at the Glasgow Exhibition two years ago. We favourably commented upon them at the time. For compactness and finish they occupy already a prominent place among engines adapted for electrical installations of moderate size. The protection of their working parts from external interference is of great importance, where, as is often the case in small installations, the labour available is not the most skilled. The engine

Digitized by Google

shown drives a 15-light Brush arc dynamo. The sixth item is a high-speed single-cylinder vertical engine. The speed of this engine is 285 revolutions per minute. It has been designed with the special object of meeting the demand for compact engines for ship lighting. All the wearing parts have large surfaces, the lubrication is automatic, the engine is well balanced, and the speed can be varied to suit requirements. A No. 7 Brush dynamo, supplying current for fifteen arc lights, is actuated by this engine. The above-mentioned plant, consisting of six engines, two of these being twin engines, is situated in the dynamo court.

Messrs. Robey have, however, in addition, three engines at the stand of Messrs. Ernest Scott & Co.—viz., one vertical high-speed single cylinder engine, cylinders 6½in. diameter, stroke 6in., speed 300 revolutions, coupled direct to a compound-wound "Tyne" dynamo; a similar engine of rather smaller size, doing similar work; and a third, still smaller. The nominal power of these engines is respectively 9, 7, and 5 horses. The whole of Messrs. Robey's work exhibited is admirable alike in design and workmanship.

(To be continued.)

Notices of Meetings.

NEXT WEEK.

ROYAL INSTITUTION OF GREAT BRITAIN.—Friday, May 30th, at 9 p.m. Paper to be read: "On Astronomical Telescopes," by Mr. A. A. Common, F.R.S.

PRICES CURRENT, 21st MAY, 1890.

Quotations at per ton, unless otherwise specified.

ANGLES, PLATES, BARS.

Messrs. G. Bailey Toms & Co., London, quote as follows:—

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER has maintained its firm position during the week, and large quantities of raw have changed hands. The speculative buying is said to have been mainly on American account for shipment to the United States, where values are at present ruling high. Stocks are steadily decreasing, owing to a better all round demand from smelters, sulphate makers, and consumers generally. The statistics show that stocks were reduced about 3,300 tons during the first fortnight in May. Should the French warrant holders continue to keep their copper off the market, probably higher rates may rule, as stocks in the hands of consumers are small, and there is a largely increased demand. Chili bars to-day are £52 15s. to £53 cash, and manufactured £66 sheets, £69 bottoms.

TIN firm, with good business doing. The small supplies from the Straits and the improved demand have helped to strengthen prices.

LEAD quiet, but with more inquiry, and prices a shade firmer.

SPELTER is a little easier, as prices had been advanced too rapidly. The stocks are small everywhere, and consequently values must continue to rule high.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

CHEMICALS: Prices of caustic soda are again lower, the demand being very slow. Soda ash is also having less inquiry, but manufacturers are well engaged. In bleaching powder a moderate business is being done at steady prices. Sulphate of copper is very scarce on spot, and there is a good inquiry for June-July and for contract to the end of the year. Crystal carbolic is unchanged. Crude carbolic is receiving more attention, but holders are not disposed to accept buyers' ideas of value. Sulphate of ammonia has secured a good advance. Oxalic acid is also dearer.

SHIPBUILDING NOTES.

ON the 8th inst. there was launched from the shipbuilding yard of Messrs. MacIlwaine & McColl, Belfast, a steel screw steamer named the "Strait Fisher," built to the order of Mr. James Fisher, Barrow-in-Furness. Her dimensions are:—Length, 174ft.; breadth, 26ft.; depth, 14ft.; gross register tonnage, 500. The engines will be of the triple expansion type, and she will be fitted with steam winches and windlass.

ON the 14th inst. the s.s. "Ingleby" was taken on her trial trip in the Tees Bay. She has been built by Messrs. R. Craggs & Sons, Middlesbrough, for Messrs. Ed. Harris & Co., of the same town. The principal dimensions are:—Length, 260ft.; breadth, 36ft. beam; and depth, moulded, 19ft. The vessel sailed immediately afterwards for Alexandria. The speed developed was 10 knots, at an indicated horse-power of 920. The engines and boilers have been made by Messrs. Westgarth, English, & Co., of Middlesbrough. The cylinders are 20in., 33in., and 54in. diameter, by 36in. stroke, and the boiler pressure is 160lb.

ON the 17th inst. the "Teucer," a steel screw steamer of 2,800 tons gross register, was launched by Messrs. Scott & Co., Greenock. The "Teucer," which has been built for the Ocean Steamship Company, Liverpool, is of the following dimensions:—Length, 335ft.; breadth, 38ft, 6in.; depth, 27ft. The vessel is intended for the London and China trade.

ON the 17th inst. Messrs. Osbourne, Graham, & Co., Sunderland, launched a steel screw steamer, built to the order of the Cardiff Steamship Company, Limited, for their line of steamers trading between Cardiff and Bordeaux. The dimensions are:—Length, 200ft.; breadth, 29ft 3in.; and depth, 15ft. 3in. She is built with long full poop, open topgallant forecastle, water ballast, web frames, and she will be fitted with triple-expansion engines by the North-Eastern Marine Engineering Company, Limited, Sunderland. The vessel was named the "Taff."

ON the 17th inst. Messrs. Wigham Richardson & Co. launched from their Neptune Shipyard, Newcastle-on-Tyne, a steel screw steamer built to the order of the Compagnie Anonyme de Navigation Mixte, of Marseilles. She is 260ft. long, 32ft. beam, and 25ft. deep, and is fitted up with accommodation for passengers in the service between Marseilles and Algiers. The engines are on the triple-expansion principle, and are also being supplied by Messrs. Wigham Richardson & Co. The vessel was named the "Tafna."

ON the 17th inst. Messrs. Robert Stephenson & Co. Limited, launched from their shipyard at Hebburn-on-Tyne a large spar-deck screw steamer of the following dimensions:—Length, 361ft.; breadth, 41½ft.; depth, 29ft. This is the fourth vessel built and engined by the builders for Messrs. F. Stumore & Co., of London. She has a large poop, long bridge, and topgallant forecastle. All the mechanical appliances on board are of the latest and most improved type. The engines are of the triple-expansion type, and indicate 1,800 h.p.; they have been constructed at the engine works of Messrs. R. Stephenson & Co., Limited, South Street, Newcastle. The steamer was named the "Glen Caladh Tower."

ON the 17th inst. Messrs. Ropner & Son launched from their shipyard at Stockton a steel steamer built to the order of Messrs. G. R. Sanderson & Co., of Hull. Her dimensions are as follows:—Length over all, 282ft. 6in.; breadth, 38ft. 10in.; depth, moulded, 21ft. 11in.; and deadweight capacity, 3,350 tons. She has a short full poop, containing a handsome saloon, with accommodation for captain and officers, raised quarter-deck, long bridge extending to foremast, and short well with side stringers continued to the topgallant forecastle, cellular bottom for water ballast, four steam winches, patent windlass, steam steering gear, and stockless anchors. She is built on the web frame principle, and her holds are quite clear, and will give large stowage for cargo. She will be fitted with triple-expansion engines by Messrs. Blair & Co., Ld., and two large steel boilers. As she left the ways she was christened "Inverness."

ON the 17th inst. the s.s. "Lomas," built by Messrs. Raylton Dixon & Co., Middlesbrough, proceeded from the Tees on her trial trip. This vessel has been built to the order of Messrs. Arthur Holland & Co., London, and is on the web frame principle, having poop, raised quarter-deck, and topgallant forecastle. Her chief dimensions are:—Length over all, 287ft.; breadth, 39ft.; depth, moulded, 21ft. 3in.; and deadweight capacity about 3,300 tons. Her engines have been built and fitted by the North-Eastern Marine Engineering Company, Ld., Sunderland. The cylinders are 21in., 35in., and 57in. diameter, by 39in. stroke. They proved very satisfactory on the trial run, and gave a speed of 11 knots.

ON the 17th inst. there was launched from the east yard of Messrs. C. S. Swan & Hunter, shipbuilders, Wallsend, a steel screw steamer of the following dimensions:—Length, 228ft.; breadth, 34ft. 6in.; and depth, moulded, 21ft. 6in. She is built on the spar-deck rule with bridge-house amidships. Her water ballast arrangement is on the cellular bottom principle, extending to the fore and after peaks. The deck machinery is of the latest and most improved type, including steam winches, steam steering gear, &c. The engines, which are of the triple-expansion type, have been supplied by Messrs. Black, Hawthorn, & Co., Gateshead, and are capable of indicating 750 h.p. The vessel, which is the eighth built by Messrs. Swan & Hunter for the same owner, Mr. T. Rodenacker, Danzic, was named the "Julia."

HOME INDUSTRIES.

LONDON, 22nd May, 1890.

The Money Market.—Money is abundant and cheap, and there is no immediate prospect of a change in these conditions. In spite of the continued lowness of the Paris and Berlin rates of exchange, discount rates are easy. There has been no marked alteration in the position of silver this week, but the Indian exchange is firm. The stock markets, though active at the beginning of the week, have failed to maintain that activity, and prices have been inclined to droop. The stocks of the "heavy" home railways were in strong request at improving prices on expectations of an extension of the stock-splitting policy among the companies, but the sphinx-like attitude of the Parliamentary Committee who are considering the three stock-splitting bills put forward by the Great Northern, the London and South-Western, and the Caledonian Railways, has rather damped the ardour of the market. American railways, though still fairly supported, are not so brisk as they have been, and in sympathy Canadian and Mexican railway securities have experienced a check in the recent steady advance. Foreign stocks have been in request, notably Turkish issues. South American bonds have been freely bought, Brazilian and Uruguayan stocks in particular. Copper mining shares have not quite maintained the higher prices reached at the beginning of the week, and gold shares have shown a dull disposition. There has been a fall in the shares of the Eastern telegraph companies. Little movement has occurred in industrial and miscellaneous securities, and the nitrate group has shown no feature of interest.

Companies.—The following companies have been registered since our last report:—Dunedin Suburban Gas Co., Ld., with a capital of £40,000; Sunderland Cycle Co., with a capital of £5,000; San Cabrian, Ld., with a capital of £140,000, to take over the San Cabrian Railway and Collieries; Mason's Paper Mill Co., Ld., with a capital of £25,000; Flax Growers' Association, Ld., with a capital of £602, to carry on the business of cotton spinners, &c.; Blackwood Gas and Water Co., Ld., with a capital of £5,000; Penrhys Rhondda Colliery Co., Ld., with a capital of £5,000; Mackie's, Ld., to carry on the business of engineers; H. & M. Southwell, Ld., with a capital of £100,000, to acquire a carpet manufacturing business; South Atlantic (African) Land and Exploration Co., Ld., with a capital of £150,000; Leon Cobalt and Copper Mining Co., Ld., with a capital of £75,000; African Petroleum Syndicate, Ld., with a capital of £10,000; Carbonate Mountain Development Co., Ld, with a capital of £65,000; Elm Spinning Co., Ld., with a capital of £70,000, to carry on the business of spinners in cotton, &c.; British and Foreign Refrigerating Co., Ld., with a capital of £50,000; Kingston Machinists' Co., Ld., with a capital of £30,000; Metropolitan Cement and Brick Works, Ld., with a capital of £10,000; Climax Patent Carbonising Co., Ld., with a capital of £1,000, to acquire certain patents.

Speculation in Pig Iron Warrants.—The Board of Management of the British Iron Trade Association have under consideration the question of the legality of dealings in pig iron warrants for speculative purposes, on which counsel's opinion is being taken. It is probable that a Bill will be introduced into Parliament for the purpose of controlling the present system of dealing in warrants.

Railways.—The gross receipts of the twenty-three principal railways in the United Kingdom for the week ending the 11th inst. amounted, on 16,159¼ miles, to £1,348,743, and for the corresponding period of 1889, on 16,031 miles, to £1,301,380, an increase of 128¼ miles, or 0·8 per cent., and an increase of £47,363, or 3·6 per cent.

The Skilled Labour Market.—During the month of April there was no falling off in the number of labour disputes which caused stoppages of work, no less than 91 being reported, many of which were of considerable importance. In the cotton trade there were nine strikes, in the woollen trade five, in the linen trade five, in the tailoring trade twelve, in the coal trade ten, in the building trades fifteen, in the iron trade five, in the shipbuilding trade five, in the engineering trade two, in the quarrying trade three, and nine among dock labourers, the remainder being among miscellaneous trades. The returns of trade societies show a slight falling off in the demand for some kinds of skilled labour, although in a few others the figures show an improvement. Reports have been sent in by 21 trade unions, showing a total membership of 219,228, of which number 4,297 are out of work, being a proportion of 1·96 per cent. The returns of the previous month gave a total for the same societies of 3,823 unemployed, a proportion of 1·7 per cent., while the proportion for March was 1·4 per cent. This falling off is chiefly visible in the shipbuilding trade and in the allied industries depending thereon. The building and house furnishing trades continue to improve, cabinetmakers being remarkably well employed. There has been some falling off in the manufactured iron trades, but steel workers are well employed. The textile trades are somewhat dull, and there is rather more labour unemployed than is usual at this time of the year. The boot and shoe trade is fairly well employed, except in the hand-sewn branch, which is rather dull. The general observations made by the reports show that ten trades are considered "very good," seven "good," and four "moderate." The falling off here indicated is only slight, but the figures for the month seem to show conclusively that in some of our most important industries the full tide of prosperity is beginning to run slack.

The Sanitary Institute.—At a meeting of the Council held on the 14th inst., Sir Douglas Galton, K.C.B., F.R.S., in the chair, a scheme was adopted for periodical examinations for inspectors of nuisances at various centres throughout England.

Electrical Engineering.—Messrs. Appleton, Burbey, & Williamson have purchased the whole of the manufacturing business of Mr. F. Geere Howard, of Cleveland Street, Fitzroy Square, W., and have transferred the plant to their works at Hatton Garden, E.C., which have been enlarged to meet the growing demand for their electrical supplies.

The Lane Fox Patents.—We hear that the Lane Fox Company are in negotiation with several electric supply companies for the payment of a royalty of 1d. per Board of Trade unit supplied and sold to the consumers. This may be taken as 12½ per cent. on the revenue for the next two years.

The Bermudas and Halifax Cable.—The s.s. "Westmeath" is about to start from the Thames with 2,000 tons, or 874 knots, of submarine cable, to be laid between Halifax and the Bermudas.

"On Principle" Strikes.—A short time ago Mr. J. Stafford Ransome, A.M.Inst.C.E., wrote a series of articles on "Strikes" for the *Globe*, more especially with the object of showing some of the disadvantages of the existence of trades unions. Some of these articles were distributed as pamphlets among the men during the late gas strikes, and the demand for copies from employers of labour throughout the country became so great that Mr. Ransome has determined to issue all four articles together in pamphlet form under the name of "'On Principle' Strikes."

The Great Tower in London.—The site of the Watkin Tower has been fixed in the neighbourhood of St. John's Wood, in immediate contiguity to the Metropolitan Railway. The other day, by the invitation of the directors of the Metropolitan Railway, a party of gentlemen proceeded by special train to inspect the spot. It is intended to begin building operations as soon as possible, in the hope that early next year the tower may be opened to the public.

Protective Paints for Ships.—We have received a catalogue of Hartmann's Rahtjen's Composition Company, Limited, 18, Billiter Street, London, E.C. It appears that the Peninsular and Oriental Steamship Company have used this excellent anti-fouling paint for the whole of their fleet for fifteen years. A large number of the cruiser class of the Navy are painted with it, as also are such notable vessels as the "Majestic," "City of Paris," &c. The first cost of this composition is greater than that of the majority of such like paints, but its lasting powers and small skin friction more than compensate.

Diving Apparatus.—Mr. Alfred E. Stone, submarine engineer, 5, Mansion House Chambers, E.C., has lately brought out a new diving helmet, which possesses many advantages. A circular metallic ring forms the collar of the breastplate, and a groove is formed in the breastplate to receive the fillet on the collar of the dress. The metallic ring is screw-threaded in sections, and the flange on the helmet is screw-threaded in sections alternate to those on the breastplate. By this arrangement the helmet can be attached to the breastplate and diving dress with great ease; there is only one watertight joint, and no screws, nuts, or loose pieces, &c., are required, neither are there any holes punched in the collar. Those who have used this apparatus express satisfaction with it.

MANCHESTER, 22nd May, 1890.

The Manchester Ship Canal.—The policy of interesting traders of various kinds in this undertaking has been steadily pursued by the directors. About a week ago a party of the principal fruit merchants in Manchester and Liverpool were conducted over the works from end to end. The import trade in fruit and vegetables is a very large one in Manchester, and has during the last few years grown so largely that the market buildings have been twice extended, and a further extension is at present projected. The Mayor of Manchester and a Committee of the Corporation visited the Deptford Foreign Cattle Market on the 20th inst., and witnessed the disembarkation of 565 beasts from the "Egyptian Monarch." The visit was paid in order to see the arrangements with a view of establishing a similar market on the banks of the Canal.

Weavers' Wages.—The difficulty as to the formation of a standard list of prices, to which we referred last week, has been rendered acute by the action of the General Council of the Weavers' Association at a meeting held in Burnley on the 17th inst. The Council determined to insist on the formation of a uniform list within fourteen days, and, failing that, to take separate action. Since the meeting, strenuous efforts have been made to agree upon a list, as it is felt that unless this course is adopted a strike of large dimensions is inevitable. Both sides are agreed as to the desirability of the step, and there appears to be no reason why it should not be taken.

Another Cotton Corner.—Rumours of an intention on the part of speculators to create another corner in cotton are rife, but there does not appear to be much ground for them. It is well known that early in the season spinners bought very freely, and there is no doubt that many of them are well supplied. Further, it is not believed that the brokers are not selling as freely as they can, or are keeping cotton locked up, and the present strong position is apparently the outcome of the free buying earlier in the season. The demand for cotton continues to be large, and new spindles are gradually getting to work. Also several large concerns are being floated which will further increase the productive capacity of the county.

The Linen and Jute Trades.—There has been a decided falling off in the amount of business put through of late, and agents for manufacturers are constantly receiving requests from the wholesale distributors to defer delivery of goods on order until advice is received to the contrary. The houses are curtailing fresh supplies to immediate and pressing wants, and it is not expected that much will be doing until three or four weeks hence, after the holidays are over and stock has been taken. In the general home trade, however, a satisfactory turnover has been effected, and even certain sections of the linen departments have been fairly active. Such articles as blinds, for instance, have been inquired for, this being the period of spring cleaning. With regard to prices, it is not thought that any advance will take place for some time to come, although unfavourable reports with regard to the Irish and Continental flax crops have appeared of late. The shipping demand is quiet, and prospects all round will not brighten up this side of Whitsuntide. The jute trade displays no special feature of interest.

GLASGOW, 22nd May, 1890.

Pig Iron.—There is no change of any consequence in the pig iron market. Large deliveries from store are still going on, and shipments are good. Many merchants report that they are daily doing a good trade with the Continent, Canada, and the Colonies. Cleveland warrants have passed out of the hands of the late large holders, and are now being offered freely at about 4s. per ton below Scotch warrants, but on these terms they readily find buyers. Hematites have been kept up by large deliveries ex store and by labour disturbances at the mines in the North of Spain.

Scotch Railways.—The Scotch railway companies are still *en evidence* in London. The practical settlement, so far as the House of Commons is concerned, of the amalgamation scheme of the North British and Glasgow and South-Western Railways has, of course, involved the defeat of the Caledonian counter-scheme. The Caledonian Railway (Conversion of Stocks) Bill has been before a committee presided over by Mr. Campbell-Bannerman, and a Bill of limited range, for the construction of some minor branch lines in Lanarkshire and Midlothian, was passed. A larger Bill seeking for running powers over the existing joint lines in connection with the Lanarkshire and Ayrshire Railway, which is at present being constructed, was debated before Sir John Dorrington's committee in the early part of this week. On Tuesday afternoon the preamble was found not proved. The Caledonian Railway have already suffered rather heavily this session in their Parliamentary contests. In consequence of the likelihood of the Conversion Bills passing the House of Commons in the course of the week, there has been a considerable all round advance in railway shares, although last week, on receipt of the news of the defeat of the Caledonian Railway Amalgamation Bill, there was a sharp fall in the stock of that company.

Cross-river Traffic at Finnieston.—There was launched on Saturday from the yard of Messrs. Wm. Simons & Co., Renfrew, a new patent elevating ferry steamer for cross-river service at Finnieston. The dimensions of the vessel are: Length, 80ft.; breadth, 43ft.; and depth amidships, 12ft. The hull is chiefly of steel, and the main deck iron. The vessel is subdivided into thirteen water-tight compartments by longitudinal and transverse iron bulkheads. An important feature in this steamer is its being able to embark or land passengers on the quay or landing places irrespective of the rise or fall of the tide. This is managed by an elevating platform, which extends the whole length of the vessel and occupies two-thirds of its width. The platform is supported by six steel columns of box-section, and by means of screws placed inside the upright columns it can be raised to a height of 15ft. The vessel has accommodation for 300 passengers, besides eight loaded carts and horses. The propelling and elevating machinery is placed amidships, and consists of two independent sets of surface-condensing three-cylinder engines, each set coupled with its own propeller shafting, and each shaft carries two propellers. Steam steering gear is supplied by Messrs. Alley & McLellan, and Brown's patent steam and hydraulic starting and reversing gear is fitted to the propelling engines. Two horizontal boilers of Siemens-Martin steel, with patent ribbed furnaces, at a working pressure of 150lb., supply the steam. The engines for raising and lowering the platform are separate, and the gear for working the elevating screws is so constructed that any variation of speed may be obtained according to the nature and extent of the load.

(From our own Correspondents.)

LIVERPOOL, 21st May, 1890.

The American Passenger Trade.—The passenger traffic across the Atlantic is now very heavy, and the season has commenced in earnest; last Saturday was an exceedingly busy day at the landing stage, for while three of the largest steamers, the "City of Rome," the "Alaska,"

Digitized by Google

and the "Aurania," left for New York with a full complement of passengers, six large steamers arrived from New York and the Canadian ports, the "Umbria" alone landing 520 passengers, of whom 450 were saloon passengers. The leading hotels are full, and special trains were despatched by the London and North-Western Railway Company and the Midland Railway Company to the metropolis.

THE NORTH WALES STEAMBOAT SERVICE.—Visitors to North Wales will have ample steamboat service this season, for, in addition to the new company mentioned last week running the "St. Tudno"—formerly the "Cobra"—another company has started with the steamer "Victoria." For a time the public will have the benefit of the competition in the shape of reduced fares; but eventually the weakest will go to the wall, and the fares will return to the normal rate. There is, however, a prospect of an improved service, both as regards speed and accommodation, being maintained, for the new boats are a decided improvement upon the old ones.

LEEDS, 21st May, 1890.

THE IRON AND STEEL TRADES.—There is no new feature to notice in the iron and steel trades of this district, except it be that at present things are a little quieter than a fortnight ago, owing to the decline in the market. A hopeful feeling, however, exists with regard to the immediate future, the belief being that when prices get more settled home and foreign orders, which have purposely been withheld, will be given out. Meanwhile, the absence of inquiry is being felt. Less is doing at the forges and steel works, though the foundries are fully employed on old orders. The engineering trade remains unchanged. The chief locomotive building shops have plenty of work, chiefly on old account, while in some shops difficulty is experienced in giving full time to the hands. Makers of hydraulic machinery keep busy. One or two trade disputes have arisen in the town within the past fortnight. As indicated in a former letter, the workmen employed in the engineering, tool, and machine trades of the district have had under consideration the advisability of asking their employers for an advance of wages. The heads of the Amalgamated Society of Engineers, Steam Engine Makers, and others have now taken a practical step in the way of trying to get additional pay for both union and non-union men engaged in the engineering trade. By means of circulars the masters are requested to consider the propriety of increasing the present rate of wages, and thus enable the "workmen to take their proper position as skilled workmen with the other large centres of industry." The men suggest that an equitable adjustment would be an advance of 2s. per week to pattern-makers, smiths, fitters, millwrights, turners, and machinists. Leeds, according to the view put forward on behalf of the men, is the only centre of the engineering trade where the workmen generally have not reaped the benefit of prosperity prevailing. The answer of the masters to the demand made is looked forward to with interest outside the trade.

THE LEEDS EXHIBITION.—This Exhibition was opened to-day in the presence of a large number of spectators. Although the arrangement of the exhibits was not quite complete, yet it was possible to obtain a good idea of the merits of the show.

SHEFFIELD, 21st May, 1890.

THE STATE OF TRADE.—No orders of importance have been placed here during the past week. There is a decided falling off in orders from marine sources. Engineers still find plenty to do in attending to local requirements for new machinery and alterations to existing plant. The Manchester tool makers find Sheffield a good market. Some excellent tools have recently been delivered, including a standard type of rifling machine. Messrs. Howell & Co., of steel tube fame, are extending their works, to enable them to deal with some heavy orders. The agricultural implement makers are very busy, and most of them are working double shifts. On the whole, trade is fairly good.

NORTH STAFFORDSHIRE, 21st May, 1890.

THE IRON TRADE.—There is no real improvement to report in the iron trade of this district. Inquiries are rather more numerous, but little actual business is being done. Many of the mills are only working half time, and some are altogether at a standstill for want of working specifications. The Midland Coal, Iron, and Coke Company have given their blast furnacemen fourteen days' notice. The company find that their stocks are increasing, and that, with the present high cost of production, it is practically impossible to make a profit. Prices rule at about £7 10s. for bars and 52s. 6d. for pig iron. Puddle mine is being sold at 15s. to 16s. per ton, and furnace mine at 9s. 6d. to 10s. 6d.

THE COAL TRADE.—As might be expected at this season of the year, the demand for house coal is falling off, and prices tend downwards. There is also a great diminution in the consumption of manufacturing fuel. This industry is being seriously crippled through the heavy cost of production. It is apparent to all but the miners themselves that the rapid rises in wages have had the effect of "killing the trade."

DERBY, 21st May, 1889.

ELECTRIC SIGNALLING.—A special monthly meeting of the Midland Counties branch of the National Association of Colliery Managers was recently held at Messrs. John Davis & Sons' All Saints' Works, Derby, where, in the large hall, a most complete and effective collection of apparatus for every kind of electrical signalling applicable to collieries was exhibited. Mr. Davis, in a preliminary address, said that electrical engineering was beginning to be very much appreciated by colliery managers, and, without venturing into the regions of prophecy, he thought it was safe to predict that in time certificates of colliery managers would include the study of electrical engineering. It is proposed that the other branches of electricity for collieries be similarly treated, for which purpose the Messrs. Davis will again generously place their works at the service of the association.

TECHNICAL INSTRUCTION.—The Derby School Board have decided to join with the School of Art and the Chambers of Commerce, in presenting a memorial to the Town Council, requesting them to put in operation the Technical Instruction Act, 1870, with the view of assisting and developing a more perfect system of science and art teaching and manual instruction, more especially for the artisan classes, than has hitherto been practical.

CARDIFF, 21st May, 1890.

IRON AND STEEL.—The output of pig iron has not yet been appreciably reduced, and there is less increase in stocks at makers' works than would have been expected. Prices are dull, and where makers have been forced to sell buyers have been able to secure bargains. Hematite iron is quoted at 55s. Steel tinplate bars are quoted nominally £5 10s., but some makers prefer to stock or turn their attention to rails rather than accept a figure which cannot leave them any profit. For steel rails there is rather a better inquiry, but for iron ore the market is flat. The strike at Bilbao means the reduction of shipments by 100,000 tons, which has caused mine-owners to advance their quotations. Rubio ore is now quoted at 15s. 3d. per ton c.i.f. Cardiff and Newport, 16s. Port Talbot, 16s. Middlesbrough, 15s. 9d. Tyne.

COAL AND COKE.—The advance of 13½ per cent. in colliers' wages seems to have given satisfaction to the men, and masters know that, on its present basis, the results of the sliding scale are often a surprise to those not fully informed as to the course of the markets. Wages have now gone up, while prices are going down, and undoubtedly the position will be reversed when wages may be reduced on a rising market. This the men should remember, as the large contracts running for periods of twelve months and more rule the average price. This week shipments have been good, especially at Penarth Dock—so much so that Taff Vale Railway stock has taken a decided step upward. Prices of steam coal are fairly steady, best steam being quoted at 15s. to 15s. 6d.; second, 13s. 6d. to 14s. 6d.; and third, 12s. 6d. to 13s.

BARROW-IN-FURNESS, 21st May, 1890.

HEMATITE IRON.—There is a somewhat slow business being done in the hematite pig iron trade, and although prices are firm at about late rates—54s. for hematite warrants—the weight of pig iron changing hands is inconsiderable. Old contracts continue to engage attention, and in some cases, where these are running out, makers are disposed to transact new business at warrant prices, although the normal values quoted by makers range from 57s. 6d. to 60s. net f.o.b. for parcels of mixed numbers of Bessemer iron. They are all the better enabled to do this, because they are now getting cheaper labour and cheaper iron ore and coke. There is again a reduction to note in stocks to the extent of 6,876 tons, making the total reduction this year 59,678 tons, and leaving the aggregate stocks at 320,964 tons.

STEEL.—A rather better feeling is reported in the steel trade, which is fairly well supplied with orders. Rails are in better inquiry, and it seems likely that some good orders will be placed while prices are down at the low figure of £5 per ton for heavy sections net f.o.b. There is also a good outlook in the Siemens-Martin department, and there are prospects of good orders. Blooms, billets, tinplate bars, hoops, slabs, and general merchant qualities are quiet.

MIDDLESBROUGH, 21st May, 1890.

PIG IRON.—There was rather a small attendance at the weekly market held on 'Change yesterday, and business was duller than ever. No. 3 G.M.B. was quoted at 41s. 6d. per ton, and small lots were sold as low as 41s. 3d. Merchants are not selling, and prefer to wait. Makers are handicapped with high wages and the large prices for coke. In warrants, Cleveland No. 3 is quoted at 40s. 7d. per ton, and West Coast hematites at 53s. 5d. per ton cash. East Coast brands are nominally 60s. per ton f.o.b. for mixed numbers makers' iron, but they may be had at less. The stock in Connal's store on Monday amounted to 118,219 tons, being 8,024 tons less that a week ago. However, whilst Connal's stores are decreasing, makers are increasing in greater proportion.

SHIPMENTS OF PIG IRON.—The shipments, though rather more favourable last week, are far behind those of last year. The difference between Scotch and Cleveland has not yet reacted upon the shipments, and indeed it is questionable if the Scotch trade is desirable to the makers with the price so unremunerative. Up to the 19th the shipments amounted to 41,008 tons, against 51,993 tons to a similar date last year. Germany and Holland have taken more, but other foreign countries have taken less.

MANUFACTURED IRON AND STEEL.—These trades are very dull, and specifications are hard to get. Iron ship plates may be had for £5 15s.; angles, £5 12s. 6d.; and bars for £5 17s. 6d. per ton; steel ship plates, £6 17s. 6d.; angles, £6 10s.; heavy rails, £4 17s. 6d. per ton, all less the usual discount free on trucks at works. Some works are running short time.

SUNDERLAND, 21st May, 1890.

SHIPBUILDING.—During the last few days there have been three steamers launched at this port—the s.s. "Taff," built by Messrs. Osbourne, Graham, & Co., North Hylton, for the Cardiff Steam Shipping Company, Ld.; the s.s. "Queensland," from the yard of Messrs. Jos. L. Thompson & Sons, North Sands, built to the order of Wm. Kish, Esq., of this town; and the s.s. "Lyell," built by Messrs. Bartram, Haswell, & Co., for Messrs. Wilkie & Turnbull, North Shields. The second vessel is the largest yet owned and registered in the port, having a displacement of 8,100 tons. Shipbuilders are reported to be in receipt of inquiries, but most of these appear to be tentative. Doubtless some shipowners may be tempted to place orders at present as material has fallen considerably in cost, but they would be acting wisely to wait a little longer.

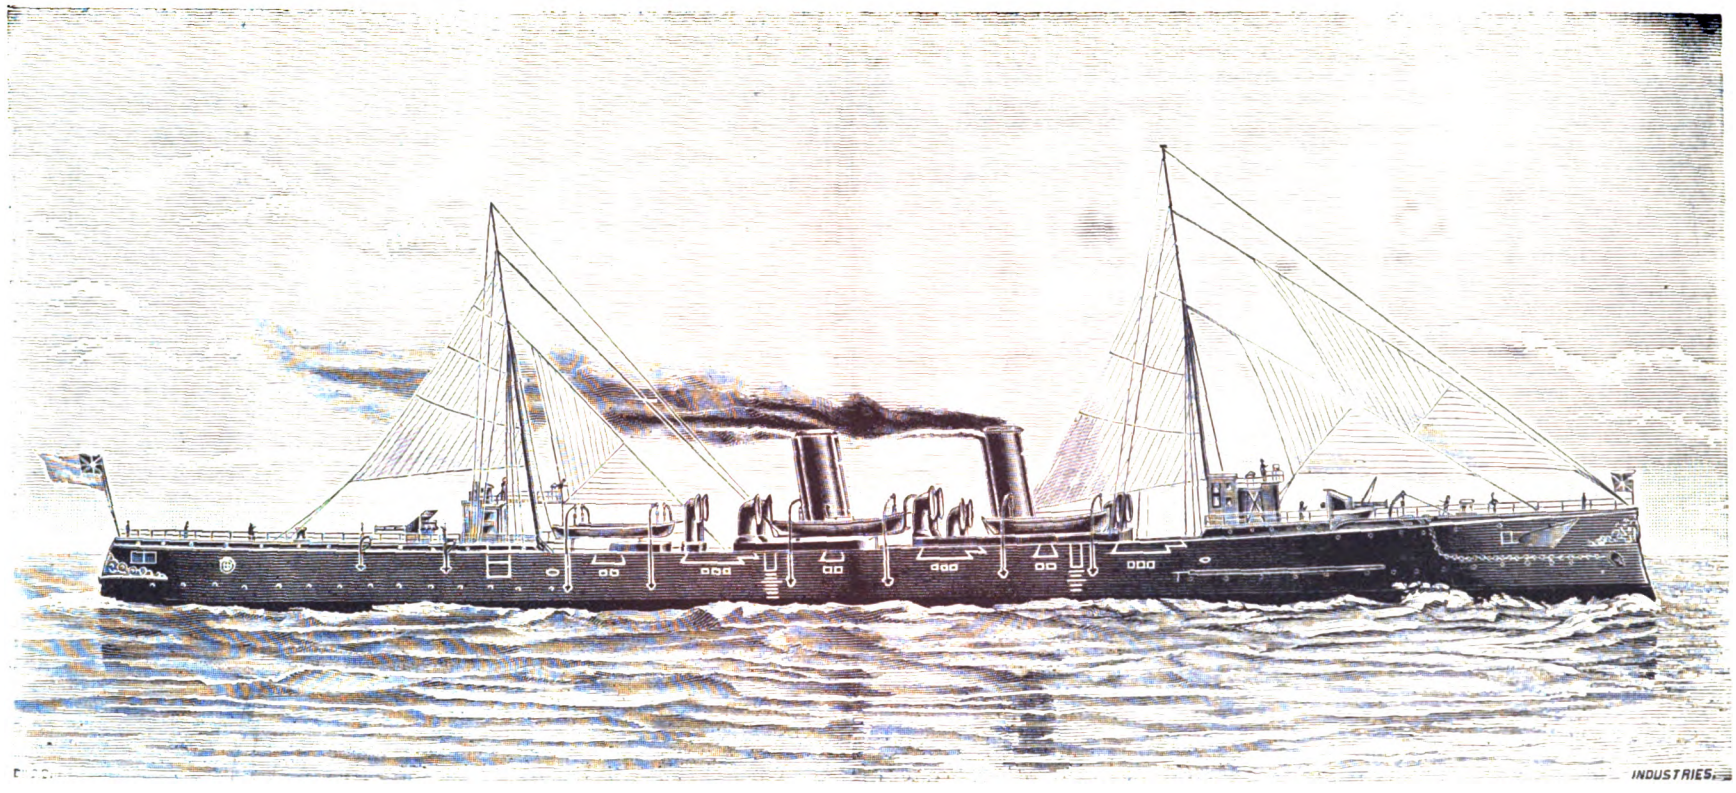
SHIPPING.—Outward freights have continued to rule low. Generally the outlook has not improved, and there is a considerable degree of uncertainty as to the future. The local import and export trade has not been so satisfactory during the last two weeks.

NEWCASTLE, 21st May, 1890.

THE ENGINEERING TRADE.—In the marine engineering establishments business continues extremely active, in spite of the fact that very few new orders are being booked. In the boiler shops there is also a good deal of work in progress, Messrs. Eltringham's establishment, South Shields, being particularly busy. The locomotive engineering works in the district are, in most cases, pretty busy, a large part of the work in hand being ordered on foreign account. Makers of steering gears and other deck accessories for steamships have still plenty of work in hand, but inquiries have fallen off, and when the orders now in progress are completed it is but too probable that a serious slackness will be felt. Efforts are now being made to give practical effect to a suggestion recently made by the employers that a Board of Arbitration and Conciliation should be formed in connection with the engineering trade of the district. Meetings of the employers and the workmen's representatives will shortly be held in reference to the matter, and it is probable that the outcome will be the early formation of a properly constituted Board, before which in future all wages disputes may be brought for settlement.

THE LABOUR QUESTION.—At a meeting of the employers and men's representatives of the North of England Iron and Steel Trade, held at Newcastle, yesterday, Mr. Jenkins, Consett, in the chair, a reduction of 10 per cent. in steel smelters' wages was accepted by the representatives for the men.

CONSETT STEEL WORKS.—Two sections of the operatives at the Consett Steel Works, numbering in all about 300, have come out on strike because the company declined to comply with their request for the dismissal of two men who had refused to join the Steel Smelters' Association. Four of the plate mills have in consequence been laid idle, and about 1,200 men, exclusive of those directly connected with the strike, are thrown out of work. Should the dispute not be speedily settled the restricted production caused thereby must seriously inconvenience Tyneside shipbuilders, whose supplies of steel plates and angles are mainly obtained from the Consett Works.



DUNDEE, 21st May, 1890.

JUTE AND FLAX TRADES.—The jute branch of the trade is again brisk, and there is a steady demand for yarns and cloth. Prices have advanced, and burlaps, 40in. 10½oz., are now quoted in New York at 5⅛c. per yard. The advance is to some extent causing hesitancy on the part of buyers here, who are only operating for the present so as to cover actual requirements. Makers are, however, well foresold, and there is a prospect of prices being maintained. There is an active demand for raw jute at advancing rates. A large business, both on spot and to arrive, has been concluded during the fortnight. Fine first marks have been quoted as high as £16. Jute yarns are sold at higher prices, but buyers are now less inclined to operate. There are rumours that some importing houses at Buenos Ayres are in difficulties, and that some orders from Dundee exporters have been cancelled. Flax spinners are well stocked, and there is little or no business doing on spot or contract. Flax and tow yarns are quiet. Manufacturers are now, however, showing more inclination to operate, and spinners of finer qualities expect that they will be able to get better prices than have ruled of late. Linen is in fairly good request, but the demand is not animated.

HER MAJESTY'S CRUISER "LATONA."

BUILT BY THE NAVAL CONSTRUCTION AND ARMAMENTS COMPANY, LIMITED, BARROW-IN-FURNESS.

LAUNCH OF H.M.S. "LATONA."

THERE was launched yesterday, from the works of the Naval Construction and Armaments Company, Limited, Barrow-in-Furness, a steel-protected cruiser for Her Majesty's Government, called the "Latona," and which we illustrate above. Unusual interest is attached to the event, as the "Latona" is the first practical outcome of the Naval Defence Act of last year. This Bill provided for the construction of twenty-nine vessels of the "Latona" class, and it was decided to build twelve of the vessels in the Royal Dockyards, while the remaining seventeen were placed with the principal shipbuilding firms in the country. Orders for three of the seventeen vessels were placed with the Naval Construction and Armaments Company, and the "Latona" is the first of these vessels to be launched, and has been put in the water in exactly nine months from the day on which the first keelplate was laid.

The "Latona," which is one of the new type of protected cruisers, is of the following dimensions:—Length, 300ft.; beam, 43ft.; and depth of hold, moulded, 22ft. 9in. Her displacement represents 3,400 tons on a mean draught of 16ft. 6in. The hull throughout is built of steel, the stern, stern-post, propeller brackets, rudder, &c., being of cast steel. The engines embrace two sets of the triple-expansion type, with cylinders 33½in., 49in., and 74in. diameter, by 36in. stroke, and are capable of developing over 9,000 i.h.p., with the boilers worked under moderate forced draught. The engines are of the light type adopted in modern war vessels, cast and wrought steel being largely introduced into their construction. The boilers have an aggregate of 16,000 square feet of heating surface. The "closed stokehold system" of forced draught has been adopted, each stokehold being fitted with two powerful fans, worked by independent engines, for the supply of air. A steel protective deck is one of the distinctive features of this cruiser; it extends fore and aft, the forward part running down with a long sweep to the ram of the vessel, of which it forms part. The transverse section of this deck is in the form of a flat arch, the crown of which rises about 1ft. above the water line at the centre of the vessel, and slopes down towards the sides to a point about 4ft. below the load-line. On the sloping part the average thickness is 2in., with a thickness of 1in. on the crown. Under the protective deck are placed the engines and boilers, magazines, steering gear, and other vital parts of the ship. As, however, in the "Latona," vertical engines have been adopted instead of horizontal, as fitted in some of the former vessels of this type, the necessary protection for the parts of the engines projecting above the protective deck is obtained by fitting a belt of 5in. of steel armour with 7in. of teak backing round the engine hatchway between the protective and upper decks. The subdivision into numerous water-tight compartments has been, as usual in warships, fully carried out in the "Latona." For the full extent of the engine and boiler space a complete inner bottom is fitted, the continuity of which is carried forward and aft by the water-tight flats forming the magazines and store-rooms of the ship. Alongside the engines and boilers amidship, coal bunkers are also fitted, formed by longitudinal bulkheads extending to the upper deck, thereby affording additional protection to the machinery. Moreover, numerous transverse bulkheads are fitted, the hull under the upper deck being thus divided into about a hundred water-tight compartments. The greater part of the hull amidships under the protective deck is occupied by the machinery, there being two separate engine and boiler rooms. Aft of the engine-rooms are situated the magazines for the supply of the after guns, as well as the steering gear, both hand and steam, fitted in two separate compartments. Forward of the machinery spaces are the magazines for the forward guns and the various store-rooms required for the ship. Above the protective deck aft are the cabins for the ship's officers, the part amidships being occupied by the coal bunkers, artificers' workshop, wash-places, &c., while the part forward is entirely devoted to the crew. Under the poop are placed the cabins of the commander and principal officers, ward-room, &c., the forecastle being taken up by the crew. The armaments of the ship consist of two 6in. breechloading central-pivot guns, one mounted on poop and the other on the forecastle; six quick-firing 4·7in. central-pivot guns, three on each broadside; eight quick-firing 6-pounder guns, four on each broadside; besides one 3-pounder Hotchkiss, and four five-barrel Nordenfelt guns mounted at suitable stations along the sides of the vessel. A 9-pounder gun for boat and field purposes is also secured on deck. In addition to these, four torpedo tubes are fitted—one forward, one aft, and one on each broadside in front of the poop. For controlling the ship in action, a conning tower of steel is fitted on the after end of the forecastle, inside of which all the gear for manipulating the engines, steering gear, guns, &c., is placed. As regards the pumping arrangements, an elaborate system of piping is fitted, extending to every compartment, while the fire service and sanitary arrangements are on the same elaborate scale. A complete installation of electric lighting is also fitted, including three powerful search lights. The steam cable gear has been supplied by Messrs. S. Baxter & Co., Sandiacre, Nottingham, and this firm are also supplying similar gear to the sister vessels now being built.

The crew numbers 252 hands, all told, for whose accommodation and comfort every care has been taken in the way of utilising the living quarters to the best advantage. Externally the "Latona," as will be seen from the illustration, has a smart appearance, having two funnels and two pole masts, with a light fore and aft rig. The Naval Construction and Armaments Company are proceeding with the building of two similar cruisers, which are to be named "Naiad" and "Melampus," and which are now in a forward state.

INSTITUTE OF MARINE ENGINEERS.

A MEETING of the Institute of Marine Engineers was held on Tuesday evening, the 13th inst., when Mr. David Phillips read a paper on the "Comparative Corrosion of Iron and Steel under Various Conditions." The Chairman introduced the author of the paper as well known to many present, but he mentioned that Mr. Phillips had given considerable attention to the subject on which the paper treated. The diagrams, casts, and experimental plates which were exhibited were exceedingly interesting, and served to show practically the course of reasoning followed in the paper. In the introductory part of his paper, the author referred to the more important papers which had been read on the subject of the corrosion in iron and steel within the last nine or ten years, and referred to a former paper he had read in 1881, before the Institution of Civil Engineers, and the subsequent discussion on that paper. He pointed out that being far from satisfied with the results, both in respect to the discussions and the subsequent papers on the subject, he had decided to undertake a series of experiments extending over a lengthened period, with a view of testing the relative merits of several kinds of iron and steel under various conditions. The results of these experiments, and his own observations upon them, he dealt with in the paper. The length of the paper did not admit of time for more than a brief discussion, in which the following members and others took part:—Messrs. G. W. Manuel, W. W. Wilson, A. W. Robertson, and G. E. Wilkinson. The usual votes of thanks to the author of the paper and the chairman were accorded, and briefly responded to.

On Saturday evening, the 17th inst., several experiments were made with Scotch anthracite coal by means of the coal-testing machine, and on Tuesday, the 20th inst., a second paper on "Electrical Engineering" was read by Mr. R. E. Crompton.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week.

All accounts are payable to GEO. CAWLEY, 358, *Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 309, Strand, London, W.C.*

FRIDAY, 23RD MAY, 1890.

THE CRITICAL POINTS OF IRON AND STEEL.

M. OSMOND'S paper on the "Critical Points of Iron and Steel," the first part of which we publish in our present issue, was undoubtedly the most important contribution communicated to the Iron and Steel Institute at their recent meeting. We gave an outline of the paper in our issue of the 9th inst., and in that of the previous week a *résumé* of the paper which M. F. Osmond had previously communicated to the Académie des Sciences on the same subject. The great variation in the physical properties of iron and steel, and the industrial importance of these variations, have not only stimulated manufacturers in their endeavours to improve the quality of their products in some special manner, but has led many investigators to give their time and attention to unravelling the causes which produce these modifications of the mechanical constants in the commercial metal. In studying the mass of literature which has accumulated in recent years on the influence of foreign elements, such as carbon and silicon, on the properties of steel, we are struck with the enormous amount of data which have been tabulated without any explanation of the causes which produce these well-known variations in mechanical qualities and physical properties of the steel or iron to which such elements have been added. It is, of course, necessary in all progress that, before any satisfactory generalisation can be established, facts must be accumulated; but in this department of knowledge facts have been accumulated at an ever-increasing rate without any corresponding development of the theories which are formulated to explain the causes which produce these results. Faraday, for example, years ago established the fact that iron loses its magnetism at a high temperature and recovers it at a certain point as the temperature cools; and Gore, Barrett, Tomlinson, Hopkinson, and many others have recorded additional facts on the amount of magnetism present in iron of varying quality and at varying temperatures, all of which information we are pleased to call contributions to our knowledge as to the influence of magnetisation on the molecular structure of iron. But although these investigators have been indefatigable in their labours, and their respective researches have certainly contributed to our knowledge so far as the establishment of facts are concerned, we still know nothing of the causes of these phenomena, and we are still groping in the dark for an explanation which may lead to a generalisation which shall at once raise the work of the metallurgist and iron and steel master to the same level as that of the electrician and the engineer. As Dr. Gore pointed out, in his recent letter to the Secretary of the Iron and Steel Institute, since 1869—when he first drew attention to the changes in the physical properties which take place when a bar of iron is heated to redness—other investigators have demonstrated more fully the variations which occur in the physical constants of the iron; and the mere qualitative fact established by Gore has been the starting point of a series of investigations which have determined in a great measure the exact magnitude of these changes, so that his statement that "simply by heating a bar of iron to redness a whole series of changes occur in its molecular structure, its magnitude, its dimensions, its exhaustive power, its specific heat, its thermo-electric capacity, and its electric conducting power," has been verified and amplified by several sets of quantitative experiments. In the same letter he points out that, as iron is magnetic and possesses one set of properties at one temperature, and is non-magnetic and has a more or less different set of properties at another temperature, it is a conspicuous example of the general truth that "every substance becomes more or less a different substance at every different temperature." The information which chemists have been able to offer towards the elucidation of these problems is still more meagre; and although within the last few years the chemical analysis of iron and steel has been regarded as a necessary adjunct to a statement of their respective physical properties, the chemist is unable to indicate why the presence of this or that element in the steel should produce so marked a variation in the mechanical tests. It is true that chemists distinguish between combined carbon and free carbon, and theorise about the alloys of iron formed by the additive elements, but little is known beyond the empirical facts of certain properties accompanying steels of a known composition. Osmond's elaborate pyrometric study of steels of known composition, and his successful determination of critical points in the molecular condition of the metal, is a step towards the generalisation which is needed from a physical point of view, and as these results fully confirm the hypothesis of Professor Roberts-Austen based on the periodic law, and therefore derived from our present chemical theories, there seems no doubt for believing that we are at last obtaining an explanation of the causes of these phenomena, which is in accord with our knowledge of the constitution of matter arrived at by independent reasoning and experiment.

M. Osmond, in the introduction to his paper, points out that his work has been that of arranging the known facts rather than that of discovering new ones, and his success seems to be mainly due to his careful re-statement of our knowledge in a way which shows the changes in physical properties which accompany alteration in chemical composition. That the molecules of iron were capable of undergoing allotropic change so that two or more varieties of the metal are possible was a fact which most chemists and metallurgists were willing to admit, and, indeed, there was abundant evidence from what is known of other elements, and their readiness to undergo molecular change, to warrant a belief in the possibility of such a change taking place in iron during a cooling or heating extending over a long range of temperature. The importance of this work appears to us to lie in the fact that the foreign elements when added have the power to alter the temperature at which these changes in the iron take place. In the case of carbon, M. Osmond admits that a third change takes place which marks the change from the combined to the graphitoidal condition and corresponds to the recalescence point of Barrett. This critical point is, therefore, one which marks the temperature at which the dissociation of the iron carbide makes itself felt to the maximum extent, and as in all dissociation phenomena the change is a gradual one, depending on the temperature and other circumstances, it is easy to see that the presence of other elements may modify the temperature at which the alteration of molecular state takes place. As Dr. Ball, in his paper on the changes

Digitized by Google

in iron produced by thermal treatment, says: "It is evident that the molecular changes which take place when iron is heated to high temperatures resemble in their nature the dissociation of chemical compounds," in the sense that in both cases the process is gradual and not abrupt, beginning at one temperature and reaching a maximum at another. When this maximum temperature has been exceeded, the products of the first dissociation may again be subject to a similar change. Further, if a mixture of several chemical compounds is treated in this manner, each compound, apart from other influences, will have its own maximum temperature of dissociation, and a curve representing the general result would show a series of maxima in accordance with the number of compounds present. Whether the critical points other than that of recalescence are due to an allotropic change in the molecules of iron, or due to the dissociation of alloys at these temperatures, will obviously not affect the value of these results. The fact that M. Osmond has obtained one of these critical points in examining specimens of the purest electrolytic iron tends to support the view advanced by the author, but in this case the change at this temperature will then be a dissociation of the molecules of α iron into the simpler molecules of β iron as the temperature increases, and the halt in the change of temperature would indicate that the supply of external heat, instead of raising the temperature of the mass, is being expended in raising the internal molecular energy of the system, the smaller β iron molecules having a greater potential energy than the more condensed α. If the view of M. Osmond be correct as to these allotropic forms of iron the alteration in temperature at which the changes take place when a foreign element is present are comparable to the alteration in the melting points and boiling points of bodies when foreign substances are introduced. Raolt's method for determining the molecular weight of bodies by noting the amount by which the solidifying point of the solvent is lowered may be cited as an illustration of the same class of phenomena, and it may be advanced as a proof that the addition of small quantities of foreign bodies which apparently do not form any chemical compound with the solvent alter the temperature at which the solvent changes from one state to another. As Raolt's method gives such promising results as to the molecular weight of bodies in the liquid condition, it may be that the researches of M. Osmond will eventually throw some light on the size of the molecules of solids, and thus be of value to the physicist as well as to the iron and steel manufacturer. Raolt's method in the hands of Heycock and Neville has contributed to our knowledge of the molecular weights of metals when in solution in another metal, and thus in Osmond's method we should have a means of determining changes in the molecular weight of metals in the solid condition.

The confirmation of Professor Roberts-Austen's law by these results of M. Osmond must not be overlooked in reviewing this work. As Mr. Snelus stated at the meeting, one point was perfectly clear—viz., that the law of Roberts-Austen seemed destined to place metallurgy on a scientific basis, a position that it had hitherto failed to occupy, and will be of itself an immense step towards furthering additional research in this direction. The changes then, in the physical properties of iron and steel are thus demonstrated to be caused partly by alterations in the molecular state of the iron and partly by the dissociation of iron compounds at definite temperatures which are determined by the chemical composition of the metal. Barus has quite recently endeavoured to ascertain how these molecular changes are brought about, and in a recent paper on the hydro-electric effect of stretching metals shows that besides β iron being produced spontaneously out of α iron above a certain temperature, as in M. Osmond's experiments, β iron may also be produced in small quantity by straining α iron at ordinary temperatures, and Carus Wilson in *Nature* has also shown that his experiments on the viscosity of strained steel support Osmond's view as to the constitution of iron. Professor J. J. Thomson, and Giese in Germany, have also recently been advancing the theory for electrical conduction in metals analogous to that of the migration of ions in an electrolyte, which further point to the metals consisting of molecules of great instability, and thus supporting the points which M. Osmond advanced in his paper before the Iron and Steel Institute.

BRITISH RAILWAYS AND BRITISH TRADERS.

The inquiry ordered by Parliament into the deposited schedules of maximum rates and charges submitted by the railway companies to the Board of Trade came to a formal end on Wednesday. The inquiry was in every way one of the most important, as it certainly was the most lengthy, that has ever taken place into the circumstances of transport in relation to the trade and commerce of the United Kingdom. If it has no other substantial result, it has brought together and crystallised a great mass of evidence and data as to the powers of the railway companies, their systems of working, their methods of dealing with trade and traders, and the missing links of railway enactment that are likely, for all time, to exercise a powerful and, it may be, a controlling influence on the relations of English railways and the population which they serve. Much money, much care, and not a little forensic and administrative ability have been expended over the inquiry. The railway companies, feeling that they were fighting, if not for bare life, at any rate for principles and demands upon which their future greatly depended, did not hesitate to employ the best skill at the Bar. The traders have mainly been represented by Mr. Balfour Browne, who, although a host in himself, has had a heavier burden and responsibility cast upon him than ought in fairness to be placed on any one man. The traders, in some cases, appeared without any counsel at all. Nevertheless, both sides have fought a good fight, and now that the battle is over it remains for the Board of Trade to determine the issues, which will, in the course of a few weeks, at the most, be presented for the consideration of Parliament.

One of the most remarkable circumstances that have been brought to light in the course of this inquiry is the fact that no common basis of railway rates and charges at present exists, after nearly seventy years' experience of railway transport, that has any claim to be regarded as exact and scientific. Railway rates are levied in the most haphazard and unsatisfactory way. In one case the exigencies of competition, in another the amount of charge that the traffic is believed to be capable of bearing, in a third the statutory maximum powers, and in a fourth the cost of the services rendered, are made the main, if not the controlling, factors in the fixing of rates. Each of these factors, again, appears to have an "infinite variety" of applications and interpretations. The statutory maximum powers of railway companies are, to the uninitiated, a puzzle compared with which the great Asian mystery would be simplicity itself. Companies like the Great Western and the London and North-Western, that have been built up out of a vast congeries of small and independent lines under Amalgamation Acts obtained at many different times, have generally a large number of Acts applying to isolated parts of their system, and under which they are entitled to levy many varying rates of charge. No ordinary trader can hope, without infinite pains and trouble, to master the intricacies of these different Acts, so that railway companies have been left to do much as it suited them, without let or hindrance, and the marvel is that traders have been content to allow matters to go on as they have done for so long. The Acts of the various companies should have been codified and their classification made uniform a very long time ago, but this undertaking, although several times attempted, has until now defied the powers of Parliament. Vested interests were too strongly arrayed against each other until the Railway and Canal Traffic Act of 1888 called forth the present inquiry.

Many grave questions, however, still remain to be decided. There is, first of all, the question of what shall be the the maxima of the companies generally, having regard to their statutory powers. The schedules deposited with the Board of Trade generally propose to have maximum powers on a high scale, the highest scale, in many cases, allowed under any one of the numerous existing Acts of the different companies. This means a process of levelling up to which the traders will never consent. It would be monstrous if, for example, the London and North-Western Railway Company, because they have powers to levy a charge of 3d. per ton per mile under some local Act, applying to a very limited part of their system, were to have powers now given them to levy that rate on their system as a whole under any particular head of the classification. And yet, according to the railway companies, it would be equally monstrous if that company were required to forego the powers granted by Parliament on that particular section, and on the faith of which the capital required to carry out the railway in question was subscribed. Obviously, if a uniform schedule of rates and charges, applicable to the whole system, is to be adopted, there must be a certain amount of give-and-take on all sides. Some powers must be sacrificed in order that others may be obtained, and Parliament may fairly be expected to take care that the powers of the future shall be fixed, not so much with reference to existing statutory maxima, as in view of the necessities and reasonable requirements of the traders on the one hand, and of the railways on the other. One example will show how deep a gulf has to be bridged over in this endeavour. The railway companies say that they should have, up to twenty miles, an average maximum mileage rate of 1d. to 1½d. for the transport of mineral traffic. The traders, or, at any rate, a very important body of them, say that the average cost of transporting mineral traffic, in full train loads, is not more than a farthing per ton per mile, and that if the maxima is fixed by Parliament at a halfpenny, it would leave 100 per cent. profit on the cost of the service. Here, then, there is a difference of from 100 to 150 per cent. between the parties, which Parliament, in the long run, must undertake to adjust. It is the cost of the service, plus a reasonable profit, on the one hand, against the statutory powers already granted by Parliament on the other. It is impossible that both parties can be satisfied, and it will be well if they can be brought so close together as to make apparently hopeless differences less prominent a feature of the negotiations than they appear to be at present. The same observations apply, *mutatis mutandis*, to the vexed question of terminal charges, which is still under consideration. The companies claim to make an arbitrary charge—(*a*) for the use of stations, and (*b*) for terminal services rendered, varying according to the position of the article in the classification, from 9d. up to 5s. 6d. per ton. The traders, for the most part, resist the first charge entirely, and demand that, if railway services are to be paid for, they must in each case be distinctly specified and charged for accordingly. There is much confusion as to the existing powers and practice of the railway companies in reference to making terminal charges, and the present inquiry will have done much to get over that difficulty, if it does nothing else.

THE CARLISLE RAILWAY ACCIDENT.

The report by Colonel Rich on the Carlisle railway accident is likely to lead to a great amount of unsettled opinion on the special circumstances connected with the accident. After a careful perusal of the evidence, we feel compelled to agree with the verdict of the coroner's jury, rather than with the opinion of Colonel Rich, notwithstanding the weight which we naturally attach to such an opinion. The jury found that the deceased were accidentally killed owing to the train in which they were travelling overshooting the platform and coming into collision with an engine belonging to the Caledonian Railway Company, and that such collision was entirely due to the failure of the brake with which the train was fitted, and they acquitted the driver of all blame. They further stated that they thought that the London and North-Western Railway Company were incurring great responsibility in using a brake of such an uncertain and unreliable character. In direct contrast to this, Colonel Rich states that, in his opinion, the collision was caused by the mismanagement of the engine-driver and consequent want of brake power to stop the train, which ran down the incline from Shap Summit at a speed of about sixty miles an hour, and approached Carlisle Station at a high speed. He evidently has taken great pains to arrive at a knowledge of the facts, and among other things he ran an experimental train from Carlisle to Penrith and back, and endeavoured to make the conditions as nearly as possible the same as those of the train with which the accident occurred, and from his observations of the driver's methods of working his brakes and the appliances connected with them, he came to the conclusion that the accident was caused by the wrong action of the engine-driver.

The statement of Colonel Rich shows how apt it *might* be for a driver to make a mistake in the management of his brakes, and such a complicated arrangement as existed in this case should never have been used. Colonel Rich recommends the London and North-Western Railway Company to put a stop to the confusion by doing away with the simple vacuum as fast as possible, and to work only with the automatic vacuum brake, and to use with it a proper amount of vacuum. The company indeed seems to have determined on this some time ago, and it is unfortunate that they did not

Digitized by Google

act at once on their decision. We admit that Colonel Rich's explanation of the cause of the accident may be the correct one, but to think so we must set aside the greater part of the evidence given before the coroner and in connection with the Board of Trade investigation. We cannot now enter into the details of that evidence, but those who read it will see at once that something apart from the action of the driver interfered with the working of the brakes. On the way from Euston to Tring the train was stopped by a message from a signalman to "stop and examine train." When the train stopped at Tring the wheels of the Gourock van were found to be red hot and jammed to the brake blocks, which could not be got off, so it was arranged to leave the van in the siding at Tring. As soon as the vacuum pipe at both ends was detached from the train, the brake blocks came off. Colonel Rich says that this would happen if the van were worked by simple vacuum while the rest of the train was worked by automatic vacuum, and he was of opinion that this was the cause of the mischief. But what was observed at Tring and at Carlisle pointed most distinctly to another cause, in the shape of an obstruction in the pipes, which might be quite sufficient to account for the accident, without putting aside the greater part of the evidence of the men who were responsible for the working of the engine. At Carlisle, when the automatic vacuum brake machinery was examined, it was found to be in good order, but half a pint of water was found in the belly of the pipe between the engine and the tender. Colonel Rich says that this quantity of water, if frozen, would not be sufficient to plug the pipe and stop the air way. Possibly not, although if there were a sharp bend it probably would. Supposing, however, that the pipe was only partially blocked by ice, the air would only pass with difficulty, which would of course increase as the obstruction increased, and would account for all that afterwards occurred. In our opinion, therefore, there is no need for the starting of a theory which *might* explain actual occurrences when we have certain facts which also account for these, and which are, moreover, supported by the evidence of the men concerned.

Letters to the Editor.

PIECE WORK.

To the Editor of "Industries."

Sir,—In your leading article, "Can an Improved Education Prevent Strikes?" a question to which I would undoubtedly answer "Yes," you deal with the subject of piece work. You state: "Officially the trade unions are generally very strongly opposed to it. To the uninitiated it may seem strange that a system which, on the face of it, is the fairest that could be devised, and by which, as a matter of fact, the highest wages are earned, should be regarded by artisans, as a body, with aversion." This is quite correct, but in your theories as to the causes I think you have omitted one. Trade unions, as trade unions, do object to piece work, but the individuals composing the unions, I believe, do not. This sounds a paradox, but I shall try and explain. The unions look on the matter in the same light as they see the eight hours day. They have to contribute money to their members who are out of work, and a shorter day will, as you point out, cause fewer members to be unemployed. In the same way, piece work causes more to be unemployed. The whole subject is looked upon in a selfish light. The union, as a body, looks after itself with a view to pay as little out of its coffers as possible; but take, on the other hand, a time work member of the union, and offer him the chance of making more money by going on piece work, and there will not be many so unselfish as to decline.

Yours &c.,
J. D. W.

THE RECENT MEETING OF THE IRON AND STEEL INSTITUTE.

To the Editor of "Industries."

Sir,—The recent meeting of the Iron and Steel Institute, although a very quiet one, and apparently not producing anything absolutely startling or progressive, seems, nevertheless, to have cleared the atmosphere, and to have placed before us the results of some painstaking investigations on the causes affecting the quality of steel. These investigations cannot fail in the future to yield results on matters which a short time back were exclusively in the domain of abstract science, but now have been placed, in a measure, in the hands of the practical manufacturer, who may now possibly be able to classify the working of metals in accordance with natural laws.

The combined researches of M. Osmond, Roberts-Austen, and others have evidently influenced the members of the Institute, and, from the tone of the discussion thereon, they appear fully to comprehend, and to be fully alive to, the importance of the papers read. It appears to me that an immense stride has been taken. The great importance of such statements that iron may—indeed, must—exist in different molecular forms, and that thus its quality is affected by such molecular variations, cannot be gainsaid.

Further, the law of atomic volumes here so clearly enunciated by Professor Roberts-Austen deserves the utmost attention, and, together with the part which initial temperature and cooling plays in determining the quality, or, in fact, the chemical modifications of the metal which seem to occur, places the chemistry of steel on a firmer basis. Probably we may soon be in a position to give a rational explanation of much which, up to the present, we have been profoundly ignorant. Hence the past necessity of coining words meaning nothing, and practically amounting to a confession of hopeless mental confusion, will therefore in the future be avoided.

The important paper by M. Osmond on "Some Critical Points in Iron and Steel" deserves the attention of those engaged in the manufacture. I find in this paper an explanation of many before to me unaccountable variations in the behaviour of steel. And it is probable that the following out of this line of research, with further experiments, combined with careful observation, will bear fruit. Indeed, I venture to suggest that our ideas as regards the chemical composition of steel may be completely revolutionised. One seems even now to realise that in lieu of the old fashioned doctrine that, with so much S, P, &c., corresponding variations must of necessity follow, has received a severe below. It follows that we cannot draw correct conclusions unless we attach due weight to the influence exerted by changes, which M. Osmond so clearly shows may occur by, roughly speaking, what may be termed mere variations in heating, cooling, and general manipulation.

The consideration of the atomic volume of the elements usually present in iron and steel will also have to be considered. For, as I understand it, it is quite possible that, of two elements, equal weights of both may be present in steel, yet the actual volume of these in combination may vary greatly, or, on the other hand, the weights may vary, but the atomic volumes may be equal. In other words, the mere percentage composition of an alloy affords only partial information, likely to mislead, unless coupled with the knowledge of the relative atomic volumes of the constituents.

M. Osmond tells us, in addition, that, in the case of iron, the metal assumes the molecular form in accordance with the higher or lower atomic volumes of the elements added. Elements of lower atomic volume than iron, preserving or increasing the proportion of β, or hardening iron; elements of higher atomic volume having the reverse action, increasing the proportion of α, or the soft modification of iron. Further, it is asserted that several of the elements, or their compounds, in Group 2, of higher atomic volume than iron, may communicate their properties to the metal. This, we may fairly infer, indeed, we already know, does occur. It therefore follows that a further study of such alloys formed with iron free from carbon, say, electrolytic iron, or, preferably, purified iron oxide reduced with hydrogen, might lead to useful practical results. In the present state of our knowledge, it seems somewhat difficult to trace the *direct* influence of the ordinary foreign elements present in steel and iron containing varying proportions of carbon. M. Osmond has, however, in some degree, explained their effect in modifying the constitution of the ordinary carbonaceous metal.

It is worthy of note that Sir Lowthian Bell asserts that when plates of iron of dissimilar composition, as regards carbon, are heated, even at the low temperature of a hot-air stove, a transfer of carbon occurs. Carbon really appears to be slowly soluble in iron; the ratio of solubility being a function of the temperature. Or, more clearly, carbon apparently is soluble in iron, obeying the same law applicable to most salts difficultly soluble in water. This seems, at first sight, somewhat outside the circuits of the phenomena discussed by M. Osmond, but it is clear that a heterogeneous mixture of pure iron must, on sufficiently prolonged heating, become homogeneous. Similarly a cast steel ingot may be a heterogeneous mixture of pure iron and carbonaceous iron, which, after repeated heating, may become, practically, homogeneous. Hence it follows that, in the heating of steel bars, as described by M. Osmond, a diffusion of carbon must occur. It is not so clear that this diffused carbon returns to its normal state on cooling.

I quite agree with Mr. Galbraith as regards the important influence which the presence of iron oxide has on iron and steel. Further, I have repeatedly urged the importance of constantly determining the amount of the oxide in iron and steel, which in my experience I have found to vary considerably. The younger generation of metallurgists appear, however, to have completely forgotten that the late Mr. Mushet at once attributed the red shortness of bloom Bessemer metal to its true cause—viz., the presence of an excess of iron oxide, and promptly suggested the addition of spiegeleisen as the only remedy. Unfortunately, owing to the influence of what may be termed mass, it appears that oxide of iron can only be completely removed by the addition, in many instances, of an injurious excess of carbon and manganese. Hence, it may be reasonably presumed that soft steels contain more iron oxide than the harder varieties, and for the same reason are more liable to boil and splutter in the moulds during casting. Probably the addition of some element of nearly the same atomic volume as iron, and of greater affinity for oxygen, might be beneficial if added just previous to casting.

Yours, &c.,
Metallurgist.

South Wales, 19th May, 1890.

THE CARLISLE ACCIDENT.

To the Editor of "Industries."

Sir,—I propose, with your permission, to offer some few remarks on the Carlisle accident, and the lessons to be learnt therefrom.

Unfortunately there is not complete unanimity between the report of the Board of Trade Inspector and the verdict and remarks of the coroner's jury. The former states that the collision was caused by the mismanagement of the engine driver, and consequent want of brake power to stop the train, that the engine driver got thoroughly confused, and omitted to do what he should have done, and did what he ought not to have done, by altering his engine to work the simple in place of the automatic vacuum brake. Colonel Rich considered that great allowance should be made for the mistakes that he made, as it must be a most confusing thing to have both the simple vacuum and the automatic vacuum brake to deal with.

The jury, in their unanimous verdict, say they acquit the driver, Rumney, of all blame, and are of opinion that he used all available means at his hand to stop the train, and that the London and North-Western Railway Company are incurring a very grave responsibility in using a brake of such an uncertain and unreliable character. This is rather strong language for a jury to make use of to a great railway company like the London and North-Western, and following, as it does, the third experiment in continuous brakes on this line. It would appear from the result that the question of brakes has not been studied by the mechanical advisers of the company with unbiassed attention.

The history of the unfortunate train on its fatal journey is most remarkable, chronicling a series of brake failures from the very start. The train at Euston consisted of 11½ vehicles, a large vehicle being counted as 1½ ordinary ones. This number was increased from time to time until at Preston the train consisted of 13 vehicles, equal to 15 ordinary vehicles. These were all fitted with the automatic vacuum brake for use as far north as Carlisle, beyond which place the Westinghouse or compressed-air brake was to be used. Before starting from Euston the van the fourth from the end failed to show the proper amount of vacuum, and, upon examination, it was found that some part of the mechanism on this vehicle was frozen. To remedy this defect the remarkable proceeding of lighting a fire of oiled waste under the brake cylinder was resorted to. It was not quite clear whether the piston had been frozen in the cylinder or whether the valve between the train pipe and the cylinder had been frozen in its passage. This valve is simply a brass ball about ⅛in. diameter, and in cold weather is quite likely to condense any moisture in its neighbourhood which may be in the train pipe. If this moisture freezes, the ball is either fastened to its seat or off its seat, as the case may be, and the brake for the time being is inoperative, although it may be all right before it is frozen and after it is thawed. The next incident to the train was at Tring, where it was stopped by signal, a signalman having noticed that the train was apparently on fire. Upon examination it was found that the vacuum brake was on, and the tyres red hot. Every effort was made to release the brake, but without success. The van was therefore unloaded and left at Tring, after causing a delay of twenty-seven minutes. A change was made here in the method of working the brake, as the automatic method had failed twice on the journey. This change to the simple vacuum system violated one of the Board of Trade safeguards. The principle of automacity having been abandoned, any failure of a coupling henceforth makes the brake useless throughout the train.

At Bletchley preparations had been made to change the method of working the brake back from simple to automatic vacuum, but upon the train arriving at Bletchley the change is deferred in order that further time should not be wasted. At Rugby the change is made and a new engine attached to the train; from Rugby forward to Crewe, Wigan, and Preston the automatic vacuum system worked satisfactorily, but when the train should have been slowed down preparatory to stopping at Carlisle it was found that the brake refused to act, both the engine-driver and the guards attempting to put on the brakes without success. Resort was had to the hand-brakes, but the brake power being insufficient to stop the train in the distance of 1½ miles it rushed through the station at the rate of from 25 to 30 miles per hour and collided with a Caledonian engine at a distance of 100 yards from the north end of the station.

The engine-driver gave it as his opinion that the failure of the brake to act was due to frost. Colonel Rich did not consider this conclusively proved, but it is quite clear that twice before on its journey the brake failed to act in consequence of its being frozen, and it is reasonable to suppose, failing any other explanation, that it was frozen on the third time when it refused to act. I think with the jury that the company using such a brake incur grave responsibilities. One of the peculiarities of the vacuum brake is its liability to be frozen, so that railway companies cannot plead ignorance on this score. From the Board of Trade Returns on brakes it is seen that from December 1st, 1886, to March, 1889, the vacuum brake has been found frozen no fewer than 106 times. Even on the day of the Carlisle accident, there was another case of failure on the London and North-Western Railway at Northampton, where the train overran the platform 100 yards, which was assigned by one of the officials to be caused by frost preventing the vacuum brake from acting.

The question naturally arises, whether the railway companies, using a vacuum for brake action, have not adopted a wrong principle altogether. The tendency of a vacuum is to produce intense cold, and hence the vacuum brake becomes a refrigerating machine. The plan adopted by the London and North-Western Railway for feeding water into their tenders by a trough between the rails is attended by a certain amount of splashing of the water under the carriages, and thus gives rise to a favourable condition for obtaining unlimited quantities of water at every leaky point. The Vacuum Brake Company, knowing the liability of their brake to take in moisture, have sundry drip pipes at intervals on their brake apparatus, but if the temperature is sufficient to freeze this water the drip pipes become inoperative.

The safety of the travelling public being of vital importance, it appears to me that it is the duty of the Board of Trade to declare themselves in no measured terms and to insist that their requirements should be carried out on every railway. It is quite clear that the companies are not to be trusted alone. Thus, after thirteen years, the London and North-Western Railway are only able to equip their trains with a brake which fails whenever the temperature is reduced a few degrees, and which, on this unfortunate occasion, killed four passengers and injured sixteen others. Surely the time has now come, Sir, when some authoritative tribunal, above the various interests of the various railway companies, should declare which is the best brake and thus prevent further human slaughter.

Colonel Rich, in his report of this accident, appears to me to favour the railway company at the expense of the driver, although he cannot at the same time avoid condemning the brake as it is now made. Of course, if the vacuum brake is improved, and improved first by the adoption of an air-pump, then by increase of vacuum, why not carry it one step further and improve the vacuum out of existence? This would then make it a compressed-air brake. I think the verdict of the jury is decidedly the more common-sense view of the accident, and that it is the railway company and their mechanical advisers who should be blamed for the slaughter of the passengers and the injury to property, and not the engine-driver who had the misfortune to handle so wretched a brake.

Yours &c.,
London, 19th May, 1890. Pressure.

BIGGS' TUBULAR LOCK.

We illustrate below a new tubular reversible mortice lock, the invention of Mr. F. J. Biggs, and manufactured by the Tubular Lock Syndicate, Limited, Leadenhall Buildings, London, E.C. The ordinary fitting of locks into doors is still a laborious operation. The oblong cavity necessary for the insertion of a mortice lock also weakens the door, and leaves very little wood for out-

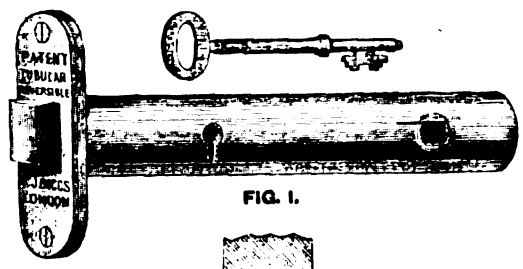

FIG. 1.

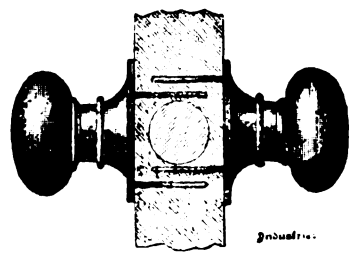

FIG. 2.

side screws to penetrate in securing the outer furniture. Fig. 1 gives a general view of the lock and key, and Fig. 2 shows a sectional view of the door in front of the knobs. It will be seen from Fig. 2 that long screws—equal in length to the thickness of the door—may be used for securing the knob plates to the door. The lock and fittings are exceedingly well made by specially designed machinery, and should command a wide sale.

THE INSTITUTION OF CIVIL ENGINEERS

At the concluding ordinary meeting of the Session, on Tuesday, the 20th inst., Sir John Coode, K.C.M.G., President, in the chair, the paper read was on "The Keswick Water Power Electric Light Station," by Messrs. W. P. James Fawcus and Edw. W. Cowan, Assoc.MM.Inst.C.E.

This was believed to be the first attempt to utilise available water power in this country for the purposes of a public supply of electric light. Early in last year the directors of the Keswick Electric Light Company instructed the authors to prepare plans and to procure tenders for the erection of a central supply station in or near Keswick. As the area proposed to be lighted was large and sparsely populated, it was seen that the only feasible system to adopt was an overhead high tension one. The alternating current transformers system was finally selected, and a site on the River Greta, about three-quarters of a mile from Keswick, was chosen for the erection of the station, the river being here available at 20 feet head. The saving effected in using this water power was considerable. The rent paid for the water was 10s. per h.p. per annum. Taking the number of h.p. hours required per annum as 100,000 for the present output of the station from a 50 h.p. turbine, the cost per h.p. came out as 0·06d. On the other hand, taking the price of steam coal at 15s. per ton, and the quantity burnt per h.p. per hour as 6lb., the cost per h.p. hour came to 0·48d., or eight times the cost of the water power. In addition to this, the attendance required for a turbine was, of course, less than that necessary for a steam engine and boiler; the first cost, maintenance, and depreciation were also considerably less, and the chances of a breakdown much less likely. As there was a possibility of partial failure of the water supply during extreme drought in summer, it was decided to provide steam in addition to water power. The turbine was of American design, and was called the "Victor." It was of a "mixed flow" type, the wheel being 20in. in diameter. Its speed was 273 revolutions per minute; this was at least 70 per cent. greater than the speed of an "inward," an "outward," or a "parallel flow" turbine would have been, working under a similar head. Its design was exceedingly compact, and the regulation, which was effected by opening and closing a cylindrical sluice working between the guide-passages and the wheel, was all that could be desired. As the turbine was 16ft. above the level of the tail race, a draught-tube was necessary to give full effect to the head of 20ft. This draught tube was of wrought iron, 14ft. long and 3ft. in diameter. The maximum velocity of water flowing through it was a little over 4ft. per second. The engine was a Westinghouse of simple type, having two single-acting cylinders 10in. in diameter by 9in. stroke; it gave with 80lb. of steam, at 350 revolutions per minute, 50·11 brake h.p. The floor space taken up by the engine was 7ft. by 4ft. The boiler was a 20 nominal h.p. Hyde duplex, 4ft. 6in. in diameter and 11ft. 6in. in height. Its working pressure was 120lb. to the square inch. The alternator, which was designed by Mr. Gisbert Kapp, and manufactured by Messrs. Johnson & Phillips, the contractors for the electrical plant, was a 30-kilowatt separately-excited machine, giving an output of 15 amperes at 2,000 volts. Its speed was 750 revolutions per minute, and the frequency 75. The armature had a cast-iron supporting-ring 28in. in diameter and 2½in. wide, provided with six arms. The armature-core was of charcoal-iron strip, 2¼in. wide, wound with paper insulation to a depth of 8in. There were nineteen coils, each containing 100 turns of 0·072in. wire, covered to 0·092in. in two layers. The resistance of the armature, after working some hours, was found to be 7 ohms. The magnetic field consisted of twelve magnets on each side of the armature. The cores and pole-pieces were of wrought iron, the yoke-rings of cast iron. The former were cylindrical, 3¾in. in diameter. The latter were 4in. by 7¼in. Each core was wound with six layers of 58 turns per layer, with 0·102in. wire covered to 0·117in. The total resistance of the field after working some hours was 11·2 ohms. At full load the energy of the field was 3 per cent. of the output of the machine. The framework was of substantial construction, and the machine when running was remarkably free from vibration. Its open design admitted of the free passage of air to the armature, which would carry 20 amperes without overheating. The magnets could be racked aside for access to the armature. The exciting dynamo was a 1-kilowatt machine of the Gramme type, giving 10 amperes at 100 volts. Regulation was effected by varying by hand the resistance in the field-magnet circuit. Two circuits left the station, both of which were double-pole fused, and provided with double-pole switches and lightning-arresters. There were some special features in the method of carrying out the overhead mains. If wire of high insulation had been used the expenditure would have been considerable, and it did not appear that any great advantage, other than increased durability of the mains, would have resulted. It was, therefore, determined to use a lower insulation for the mains, and to rely upon the points of support for insulation, also to use special arrangements for cutting off all surface leakage where the wires entered the consumer's premises. The authors were not aware that attention had been paid to this point before, yet it would seem that in wet weather, upon a long line of overhead mains, even with the best insulation, the surface leakage, when high tension currents were employed, would be considerable; and if devices were not adopted for cutting this off where the wires entered buildings, leakage to earth must result, which might be a source of danger as well as of loss. The mains at Keswick were being insulated from earth, and from each other, by oil throughout the system. The house leading-in wires were insulated with vulcanised india-rubber of the highest quality, and were threaded through a shackle oil insulator, the wire being cemented in with Chatterton's compound. Such an arrangement should effectually cut off surface-leakage from the mains. The leading-in wires entered the roof through a stone-ware pipe, provided with a covering piece to keep out rain and cover a reservoir of oil in the mouth of the pipe. The sizes of the mains were fixed for a current density of 500 amperes to the square inch. The fall of potential, between the generating-station and the town, was only slightly above 1 per cent. at full load. Steel suspension strand was used for supporting the mains for all circuits, consisting of three strands, each strand being 14 B.W.G., and galvanised. One short run of underground mains was being tried, the Brooks fluid-system being used. This system had much to recommend it; it was simple, cheap, and durable, and did not take long to lay down. The transformers were Kapp's patent, and they transformed the high-tension current of 2,000 volts to 100 volts. A double-pole, quick-make and quick-break switch, with double-pole fuse and lightning-arrester, was used in the high-tension circuit with each transformer. Both the transformers and the switches were enclosed in cast-iron water-tight cases. A series of experiments had been made to test the efficiency of the machinery, with the result that the total efficiency of the generating-plant at the station came out at about 40 per cent. at ¼ full load, and over 70 per cent. at full load. In connection with the arrangement of this central station scheme, the authors had occasion to make a comparison between the illuminating power of the glow lamp and gas; the results showed that the relative values usually given were misleading, as they almost invariably dealt with a standard London argand, a burner seldom used for ordinary lighting. This burner was generally taken as giving from 15 to 16 candle-power for 5 cubic feet of gas consumed per hour; whereas, out of a large number of ordinary burners taken haphazard, and tested where they were in use, in Chester, Manchester, and Keswick, at various times, it was found that the light given by 5 cubic feet of gas per hour was more frequently equal to 8 candles or less. This would show that, in practice, one 16 candle-power glow lamp gave approximately the same degree of light as two ordinary burners each consuming 5 cubic feet of gas per hour. This conclusion seemed to be borne out by the result obtained by Dr. Hopkinson, who, experimenting upon some ordinary burners, found the average candle-power to be 1·76 per cubic foot of gas. As regarded glow lamps, Sir David Salomons found that 100-volt 16 candle-power Edison Swan lamps averaged 17 candle-power at 100 volts. The light had been received with great favour at Keswick, and already the demand was equal to the supply of the present plant. Supply was commenced at the beginning of the year, and the station had run without hitch up to the present time—a man and a boy being found sufficient for tending the machinery.

Reviews.

Alternative Elementary Physics; being a Course of Lessons, adapted to the requirements of the new Syllabus of Physics recently instituted by the Science and Art Department. By John Mills. London: Chapman & Hall, Limited. 1890.

This is a type of book which has been produced to meet the requirements of the Science and Art Department Examinations, and contains just sufficient to cover the syllabus of the Department in the alternative subjects of Physics. It is a type to which we strongly object, as in the nature of things it must be very much a cram book. As such no doubt the author has done his best to make the book suitable for the examination, and he has succeeded in making it both readable and fairly accurate. The subjects of sound, light, heat, magnetism, frictional electricity, and voltaic electricity are dealt with, about 25 pages being given to each. On page 27 there is a misprint for hole, and Fig. 14 on page 29 seems to be altogether wrong and unintelligible, unless for "rod" we read "sphere." If the circle to which the tangents are drawn is intended as an end view of the rod then the shadow shown is impossible. In experiment 19, page 32, something is wanting, and the description may be made much clearer in a future edition. On page 41 it is stated that: "When light passes from one medium to another it is bent out of its straight course." This is too general, for it is not so in the case of perpendicular incidence. On page 46 "plain" has been written for "plane." A specimen examination paper is given at the end of the book, which is fairly adapted to the examination for which it is intended.

Transactions of the Institution of Engineers and Shipbuilders in Scotland. Vol. XXXII. Session 1888–89. Edited by the Secretary. Glasgow. 1889.

In the absence of the President, Dr. Kirk, the thirty-second session of the Institution of Engineers and Shipbuilders in Scotland was opened by one of the Vice-Presidents, Mr. Dyer, with a paper on the "Horse Power of Marine Engines." Mr. Dyer's remarks were founded on a report on the subject which had been issued by the North-East Coast Institution of Engineers on the subject, and the paper was written chiefly for the purpose of obtaining an expression of opinion from the Scotch engineers. Mr. Dyer himself did not think the proposed formula of the North-East Coast Institution would serve any useful purpose, and he proposed that, till some satisfactory method of measuring brake horse-power has been devised, that the indicated power should be adhered to, as the most generally satisfactory measure which could be adopted. In the discussion which followed a considerable number of opinions were expressed. The proposal of the North-East Coast Institution was defended by Mr. Weighton, who had a good deal to do with its origin, and who, as a former Clyde engineer, was also acquainted with Clyde practice. The general drift of the discussion was shown by the concluding remarks of the President, Dr. Kirk, who expressed the opinion that a formula such as that proposed by the North-East Coast was of no use, and that the ordinary rational formula not only covered present practice, but was also sufficient for all calculations which were necessary to meet the changes which took place in practice. He, moreover, thought that nominal horse-power was fast passing into disuse and was dying a natural death, and he thought it was best to let it so die out. No formal resolution was therefore come to on the subject by the Institution.

Mr. Andrew S. Biggart continues his series of papers on the Forth Bridge, which, when complete, will form a valuable permanent record of the progress, methods of construction, and design of that great undertaking.

Digitized by Google

Professor Jamieson has a paper on the designing of continuous current dynamo machines, which should be of great use in drawing office work, as the formulæ are all put into a shape which allows them to be directly applied. Mr. Dyer's "Notes on Some Recent Steam Engine Trials" give a digest of some recent experiments, and show the lesson to be drawn from them. In connection with marine engine efficiency, the paper by Mr. Kemp on his "Compound Marine Boiler" will be read with interest, as it marks a new departure in steam boiler design. Professor Jenkins, of Glasgow University, has an important paper "On the Stability, &c., of Oil Carrying Steamers," and in view of the importance which such steamers are now attaining it comes at a very opportune time. The other papers in the volume are two by Mr. George Thomson and Mr. F. I. Rowan, "On Smoke Prevention," "Forced Combustion," and allied subjects; one by Mr. Ivy, on his "Valve Gear and its Results"; "On a Special Apparatus for Working Sails," by Mr. John Hastie"; "On Dredging and Dredging Appliances," by Mr. Andrew Brown"; and "On Evaporation," by Mr. Charles Lang. Altogether, the contents of the volume are varied and valuable. We are glad to observe that the Institution continues to prosper financially and as regards the number of its members.

THE FRENCH EXHIBITION.

Want of preparation is one of the usual faults of exhibitions, the Military Exhibition at Chelsea having been one of the few exceptions to the rule. The French Exhibition at Earl's Court, which was opened on Saturday last by the Lord Mayor, forms a conspicuous example of backwardness, and on the doors being opened it was found that the industrial portion consisted mainly, not of the Shakespearian "beggarly array of empty boxes," but of unpacked boxes, and as no catalogue was available it is impossible even to say what was supposed to be there.

The classification includes vegetable products, textiles, minerals, metallurgy, machinery, electricity, chemicals, and pottery. There is no steam power except for the electric light, and the sole mechanical exhibits in place were a Swiss embroidery machine and a small aërated water plant. The art section and grounds were in good order, and the Executive has arranged for a varied series of amusements.

The electric lighting machinery was in good form. The lighting of the Exhibition has been carried out by the Gülcher New Electric Light Company, of Battersea, the laying out of the work having been executed by Mr. Guy Fricker. The same firm were entrusted last year with the lighting of the Spanish Exhibition, held at the same place, but the present installation is on a different plan. The driving power consists of the following:—A Davey Paxman compound horizontal fixed engine of 70 n.h.p., and indicating up to 200 h.p. It works at 120lb. pressure and 100 revolutions. There is another Davey Paxman engine, girder type, of 40 n.h.p., indicating up to 130 h.p. and running at 110 revolutions. It was intended to have a third Davey Paxman fixed engine, but owing to pressure of time a 30 n.h.p. double cylinder high-pressure portable engine, by Ruston, Proctor, & Co., was employed. This indicates about 80 h.p. Steam is supplied from three Davey Paxman boilers, each of 40 n.h.p. The total production of steam is 10,000lb. per hour.

The power from the engines is transmitted to a countershaft supported on seven standards and running at 230 revolutions. In all there are ten dynamos, the e.m.f. of each being 70 volts at the terminals. They consist of four 40-unit Batterseа compound-wound dynamos, four 20-unit Battersea dynamos, one 2-pole 20-unit machine, and one 4-pole 30-unit machine. The machines, most of which have been specially made for the present job, are well turned out mechanically. They are fixed on sliding rails to take up the slack of the belt.

The ordinary type of switches common for temporary arc installations—one switch being arranged for each group of five or six lamps—is employed. Above the switches is erected a very large resistance frame, consisting of a considerable number of coils, one resistance coil being provided for each arc lamp. A sliding contact is arranged on alternate coils to regulate the resistance as desired. Thus the current from the dynamos passes to the switches, and through the resistance coils, which are so arranged that the pressure at the terminals of each arc lamp is about 50 volts.

The low-tension Gülcher system is used, and each arc lamp is fed from a separate lead. The object has been to avoid the use of a heavy cable, which would be injured by the attachment of feeders, as the installation is of course only of a temporary character, and the present cables can be taken down and used again, as they will not be materially damaged.

There are in all 200 arc lamps installed in the buildings and grounds, 110 being of 3,000 c.p. and 90 of 2,000 c.p. In addition there are, in the "Welcome Club," theatre, and elsewhere, some 300 incandescent lamps.

IMPROVED OIL-MEASURING PUMP.

Constructed by Messrs. Dutton & Co., Worcester.

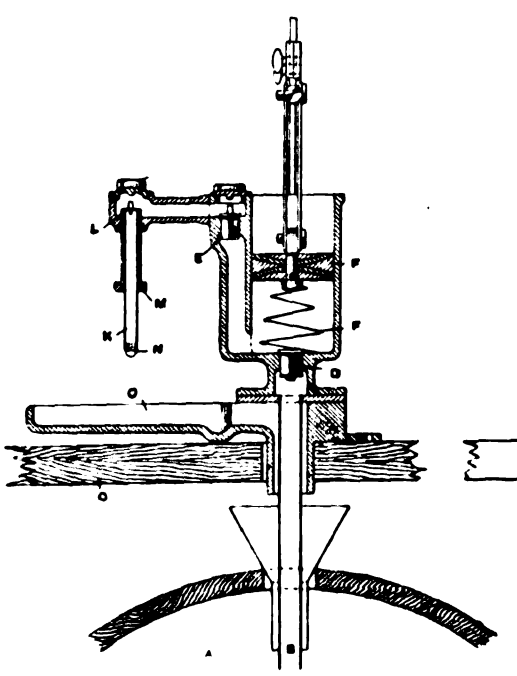

Fig. 1.—Vertical Section.

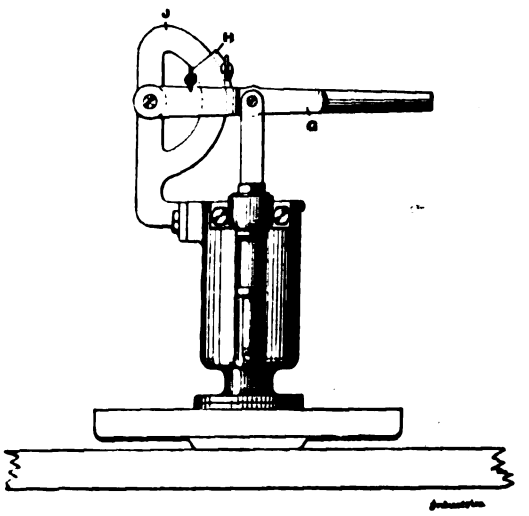

Fig. 2.—Elevation.

DUTTON'S OIL-MEASURING PUMP.

The apparatus we illustrate above was specially designed to charge the oil cisterns of railway signal, carriage, ship, and other lamps, and to exactly measure the quantity supplied. In Fig. 1 A represents the oil barrel out of which the supply is drawn; into this descends the suction pipe B, the pump itself being mounted upon some suitable bench C; the top of the suction pipe is provided with a valve D, and the delivery pipe with a valve E. The piston F is packed with leather as shown, and is worked by the lever G. An adjustable stop H is placed upon the sector J, by which the travel of the piston is regulated so as to deliver an exact measured quantity for each stroke of the lever after a few preliminary strokes have been given to fill the pipes. The piston is provided with a coiled spring P, which causes it to rise after having been made to descend by the lever G. The delivery pipe ends in a sliding tube K, which is shaped as a valve at the top L, and slides easily through the packed gland M under the valve L. The tube is perforated with several holes, and at the end N it is formed as a strainer. When it is required to fill a lamp the tube is inserted, and the lamp lifted, until the bottom of the cistern strikes the soft button and lifts the tube K and valve L off its seat; the oil is then free to pass down the tube into the lamp, the required number of strokes are given, and the valve is allowed to drop back on its seating. The tray O catches any overflow and returns it to the barrel. The pump is manufactured by Messrs. Dutton & Co., of Worcester.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

At the meeting of this Institution on the 15th inst. Major Cardew read a paper on "The Treatment, Regulation, and Control of the Electric Supply by the Legislature and the Board of Trade." The paper, which was of some length, was a new departure, both as regards the discussion before a scientific society of questions which are even more remote from their usual subjects than the commercial matters which are occasionally introduced, and as regards the still more unprecedented appearance of one of the chief officers of a Government Department to explain before a public body, not only some of the recent results of legislation, but the principles and method of treatment which they embody. "Ignorance of the law," says Selden, "excuses no man. Every man must be taken to know the law; to hold the contrary would be to confer a premium on ignorance, which would afford a defence to every possible transgression of the law." The electrical trade is, we think, greatly indebted to Major Cardew for the exposition of the recent Acts and Model Orders, and his paper, although the author disclaimed that it was in any sense official, will be studied with interest by those who have no time to wade through the wordy documents which formed its subject.

The author begged that questions of policy might not be discussed, but this request could not be taken to mean more than that he deprecated being placed in a defensive attitude. The tone of the discussion, of which a brief abstract will be found below, showed that strong views are held on the subject of over-legislation. This over-legislation is an instance of the socialistic meddling which was discussed in the House of Lords on Monday night. The Prime Minister then observed that no irremediable evil will be the result, though a certain amount of legislative goose-step will be performed, and that we may trust the nature of things to show that the State must not undertake work which can be done by anybody else, and that legislation must not undermine private rights or destroy confidence, upon which alone the machinery of capital and industry depends.

In the discussion which followed the reading of the paper,

Mr. R. E. Crompton expressed his opinion that the electric lighting industries had suffered considerably from over-legislation, and he disagreed *in toto* with Major Cardew's statement that the Act of 1882 did not do the amount of harm generally attributed to it. He admitted that over-speculation in electric light patents had a depressing effect, but he himself could vouch for the fact that the Act of 1882 prevented one large central station from being proceeded with. Otherwise the experience for which we had now to go to America would have been gained first hand. Under present circumstances it was necessary to keep the positions of sites for stations a secret, and this necessity caused hurried designs and workmanship, as well as increased cost. He firmly believed that the old method of obtaining private Bills as for gas works, would have been far more satisfactory to everybody than the present system of Provisional Orders, and he felt quite sure that the gas works clauses could have been easily modified to make them applicable to electric lighting stations. Whilst fully admitting that the Board of Trade had done all in its power to make the Acts workable, and that the thanks of all interested were due to the officials for the great efforts they had made, he could not help thinking that the tendency of modern legislation was to interfere too much and to show people how to do their

Digitized by Google

own work. The case quoted by Major Cardew as to consumers being entitled to the choice of two pressures, one about half the other, was, in his opinion, one of undue interference, for it was quite as much a pure commercial question as whether a grocer should make up his tea in pound or half-pound packages. Another case of injustice occurred where the supplier is required to provide larger terminals when a greater supply was needed by a consumer than he originally estimated.

Mr. G. Offor endorsed Mr. Crompton's remarks about the Board of Trade officials being always anxious and ready to deal practically with the questions which arose. He also thought that we suffered from over-legislation. One serious defect of the present system was the inordinate length of time required to obtain a provisional order, for the preliminary order must be applied for in July, whilst the confirmation of the order cannot be granted until August in the following year. Should an unexpected dissolution of Parliament occur in the interval, the consequences would be very serious to the applicants. He submitted that a great improvement might be effected by materially shortening the time between the application for, and confirmation of, provisional orders, or, better still, by avoiding the necessity of obtaining confirmation Bills. As this confirmation was not required for licences, he thought that orders might be treated similarly. As to the position of local authorities being more favourable than that of private companies under the Acts, he thought this a distinct advantage, for it would facilitate procuration of capital for carrying out lighting schemes, whilst private manufacturing companies would obtain the contracts without incurring all the risk.

Mr. J. Shoolbred thanked Major Cardew for the concise account of provisional orders which he had given to the Institution, and referred to the necessity for bye-laws and the question of overhead wires.

The discussion was then adjourned until the 22nd inst.

THE ARC LAMP ON ALTERNATING CIRCUITS.

The whole subject of the arc lamp on alternating circuits wants thrashing out. Many authorities hold that alternating arc lamps should be avoided because of their inefficiency. The power is distributed over two craters, so that the light is, roughly speaking, only equal to that of two direct-current arcs, each taking half the power. In addition to this, one crater is on the lower carbon, and wastes most of its light by dispersing it upwards into space. Special direct-current circuits are sometimes run for the sake of the arc lamps, as, for instance, in Chelmsford. The efficiency may be lower, though we do not remember having seen any tests; but still it is advisable to run arc lamps from alternating circuits, as any inefficiency is more than balanced by saving the cost of extra direct-current plant.

Alternating arc lamps may be run from 100 volt circuits two in series, or from 50 volt circuits in parallel, or in series circuits. The latter plan has been adopted by the Westinghouse Company, who have worked out a complete alternating arc system, beginning with the dynamo and ending with the lamp. An arc system worked out by the engineers of the Westinghouse Company is sure to have received the greatest attention in every detail, and to be good practically; but many of the points in it seem so curious that they awaken discussion.

The arcs are in series, on transformers; where convenient there are three or five lamps to a transformer, in other cases there is a transformer for each lamp. In a series system the transformers merely prevent the dangerous pressures from coming into the houses; they have no other effect of importance, and may therefore be left out of the discussion. There is, of course, a slight loss by resistance, which has some inappreciable regulating tendency. It may also be remarked that the loss of power in the iron does not go on when the lamp is not in use, as short-circuiting the secondary of a series transformer reduces the induction to very small values. The extraordinary thing is that the Westinghouse Company should work out a series system when they have, in most of the towns where they will instal arcs, a parallel system already running. The series dynamo is specially designed to give a "drooping" curve, but this result can be very easily obtained in parallel work by means of a choking coil, and the choking coil allows single arcs to be run off 100 volt circuits with steadiness and economy, an advantage, of course, unattainable on direct circuits. We can only hazard a guess that arc lamps have been tried two in parallel on a 100 volt circuit and did not work well, and that choking coils with closed iron circuits were also tried without success. It does not seem to be generally realised that a choking coil should always have an open iron circuit.

The need of a drooping curve for the satisfactory working of the lamps used is shown by the design of the dynamo, whose armature current reacts powerfully on the field; or, as it is commonly put, has a large coefficient of self-induction. This reaction is said to be so great that the armature current does not increase above the normal even on short circuit. This is, of course, impossible; still the armature reaction is very great. Now this reaction has an effect very similar indeed to that of a choking coil in the circuit; why then, should the lamps not be run off the parallel circuits with open iron circuit choking coils?

Another innovation is the change from 130 to 62 periods per second. Of course the pitch of the objectionable hum is thus lowered an octave, from tenor C to bass C in fact. There is also less trouble in making electromagnets. A given electromagnet which, with a frequency of 130, gives, with a certain pull, a back pressure of, say, 20 volts, gives the same pull with only 10 volts with a frequency of 62, or, in other words, it chokes less. Apart from these small matters we cannot see any reason for altering the frequency. The whole subject is so important that it is earnestly to be hoped that the Westinghouse Company will put the public in fuller possession of the considerations that have led to their latest departure.

ELECTRICITY AS A HASTENER IN THE TANNING OF HIDES.

It is somewhat remarkable that so little application has been made of electricity to industrial processes in which chemical operations are involved. If the metallurgical operations of electro-depositing and electric smelting be excepted, the Cassel gold chlorination, Hermite's bleaching, Webster's sewage, and Figgé's unsavoury process for "de-gumming" rhea fibre have alone been tried on any large scale. Regarding an electric current as a mode of conveying energy, it has to compete with heat and the various forms of chemical energy, the applications of which entail generally a comparatively small outlay for plant; but where a distinct local effect, or where the action of so-called nascent elements is required, it would seem that electricity might frequently be employed with economy.

Many of the most important chemical processes of the day have been worked out in the laboratory by the patient applications of chemical principles at the hands of skilled chemists, and in this respect the electric method of tanning is singular, since we have not been able to hear of even the existence of a chemical hypothesis to account for its results. The British Tanning Company have recently started at Rothesay Street, Bermondsey, London, S.E., a practical method of tanning "by electricity." The company was formed about a year ago to work in this country the patents of Worms and Ball, who, after many experiments, managed in Paris to successfully overcome the difficulties which Goulard and the earlier investigators in this direction had met with. It will be within the recollection of many of our readers that at the Paris Exhibition several specimens of leather tanned in France by this process were shown in the saddlery department. The English company at first started with a small plant of French manufacture, but they have recently erected a new series of drums, which have been at work for some weeks past, yielding very satisfactory results. In the present process, the hides, after the usual liming and depilating process, are transferred to large wooden drums, nearly 12ft. in diameter, and as many feet in length. These are mounted on a horizontal axis so arranged as to permit of being slowly rotated by steam power. Each drum is then charged with about 500 gallons of ordinary tanning liquor of about 20° strength, made from either oak bark or chestnut, and, after the addition of a small quantity of turpentine, is hermetically sealed. Thus far, the method differs but little from the various processes which have been tried with small success to substitute for the hand labour involved in daily turning the hides a mechanical movement to the tanning extract and suspended hides. In the electrical process which we had an opportunity of seeing at work last week a few feet of copper wire, forming the electrodes for a current which enters at one end and leaves at the other, are fastened within the flat sides of the rotating drums. The copper electrodes are provided on the shafts outside with rubbing contacts, consisting of ordinary dynamo brushes, to which the leads from a small dynamo are attached. At the Bermondsey works there are five such drums, and a current of 12 amperes at a pressure of 70 volts is used, or about 14 volts for each drum. The joint effect of this mechanical agitation of the pelts and liquor and the passage of this low density current is stated to reduce the time required to successfully tan half a ton of hides per drum from several months to four or five days. After working for some little time a slight heating of the liquor is noticed, and the electrolytic gases produced exert a small pressure within the drum, which is controlled by a spring valve, but no data seem to be forthcoming as to what influence this increase of temperature and pressure have upon the result. The former effect might of course be obtained more economically, while the latter is in this case small, and has been applied much more elaborately in the hydraulic process of Spilsbury in 1823, and the vacuum process of Knowles and Duesbury, both of which failed many years ago.

We are informed that the simple mechanical agitation has been found to reduce the time necessary for tanning to one half, the rest of the great economy being attained by the inexplicable electric action. It is obvious that it is extremely difficult even to devise experiments which would be successful in differentiating the part played by the various forms of energy which apparently influence the result, but until this is done a full explanation of the increased rapidity of the tannage is impossible.

A considerable stock of finished butts and skins were on view at the time of our visit; and in the opinion of experts the tanning process was stated to be fairly complete and well struck through, but the butts were generally more supple than is considered advisable for boot soles. The continual mechanical agitation in bulk would naturally open the pores of the hide; and it is suggested, somewhat vaguely, that the electric current has a similar effect, presumably in a manner akin to the action of a current on osmosis and dialysis, though in this case there is no definite direction, as the hides are being continually churned in the liquor. Turnbull, in 1845, patented a process in which endosmosis of the liquor through the pelts was hastened by forming them into bags, into which the ground tanning material was placed, together with water, and then immersed in a strong extract of catechu, but the method has not found favour with manufacturers generally. It is difficult to see what useful electrolytic action can take place, for it is not claimed, as in the bleaching process, that any chemical changes are produced, nor would such action favour any ferment of the liquor or dehydrating action.

The chemistry of the tanning process is still very obscure, and, as we have already pointed out, there is a great deal of systematic scientific research required before a satisfactory explanation of the new method can be given. Although the electric current does undoubtedly do a small amount of electrolytic work within the drum, it is probably confined to the water and inorganic salts present, as it has yet to be shown that complex molecules of the gallic and tannic acid type can be decomposed in this way. It must not, however, be forgotten that all tannins are characterised by a great avidity for oxygen, and it may be that a temporary oxidation of the active tanning principle renders it in a position to enter more readily into condensation with the gelatine of the pelt. It has been suggested that the action may be analogous of that of a mordant in dyeing, the ions liberated by the electric current determining the motion of the tannin molecules in the solution towards the gelatine. It is difficult to imagine that the electric current has any direct effect on the condensation of the gelatine and tannic acid in the production of leather, as there is no extraneous evidence to warrant the assumption that the electric current is capable of acting as a dehydrating agent. In the production of leather from the simpler molecules one would imagine that heat would be evolved, and that, therefore, it would be unnecessary to furnish additional energy to bring about the change.

The system at work at the British Tanning Company's place does not stand alone, but the results, unintelligible though they be, are confirmed in a highly satisfactory manner by a different application of electricity under the Groth patents, which have recently been tried on a less extensive scale by Messrs. Tebbitt Bros., also of Bermondsey. Here a circular vat (of somewhat smaller dimensions than the drums of the British Tanning Company) is provided, with a central shaft and eight strong arms of wood, four at the top and four at the bottom. On these the hides are firmly fastened, and the whole revolves like a huge paddle, the vat being stationary, like a brewer's mash tun. At opposite ends of a diameter, two vertical strips of copper are placed against the sides of the vat, and a current of about 12 amperes is passed. Here there is no appreciable heating, and, of course, no pressure. The hides, so far from being continually churned together, are not even subject to the ordinary daily handling, but remain strained flat during the whole operation. In stiffness and thorough tanning the resulting butts are admirable, and apparently are better adapted for boot soles and other purposes requiring a hard leather than that now being produced in the rival process. The copper electrodes waste away, as might be expected, but the British Tanning Company can discover no injurious result, nor can they detect its presence in the leather. Messrs. Tebbitt Bros., on the other hand, partly attribute the colour of their leather to the presence of copper, and propose to use an alloy in its place, though we should imagine that carbon electrodes

Digitized by Google

would overcome this difficulty. In specimens of the leather manufactured by this latter process, which we have inspected, the colour was much darker than that of the former, but we understand that the butts were tanned by a prepared extract, which is well known gives a darker colour than when a bark liquor is employed. One would imagine that in the Groth process the stretching of the pelts upon the wooden frames would facilitate a regular and uniform tannage, while in the alternative process the beating and flapping of the loose hides against one another and the sides of the revolving drum would have a tendency to soften the leather.

It seems a pity to ask too much of so promising a system. To reduce the time at one bound from many months to a few days is to spur a willing horse. Messrs. Tebbitt Bros. prefer to feed the hides with a weak liquor first, and are satisfied if the tanning is complete in two or three weeks. A strong liquor acts at once on the outer surfaces, and prevents the process from extending to the middle of the hide, and though we did not observe that this was the case at the British Company's place, we think that another fortnight in an ordinary pit would give greater firmness to their butts. The whole economy is one of time—there are no complications of new or cheaper chemicals, or utilisation of waste products; indeed, there is the introduction of motive power and electric machinery; but the advantage consists in the reduction of the large idle capital which lies in the tanner's yard in the form of costly liquor and half-tanned leather, besides the possibility of a rapid turnover and economy of space. The amount of energy expended in electricity is very small: the British Tanning Company use the current for twelve hours out of forty-eight, and its cost for the half-ton of hides tanned per drum at 8d. per Board of Trade unit would be only 3s. 4d.

More than forty years ago Peter Barlow wrote:—"Of late years considerable changes have taken place in the modes of tanning, so that this operation, which a few years ago took several months to complete, can now be done in as many days;" but he goes on to say, "the leather, however, made by this hastened process is considered to be less perfect than by the old method, an opinion which is supported by many eminent tanners and scientific men, among whom may be mentioned Sir Humphry Davy." While the former part of this quotation exactly expresses the result of the electric methods of tanning, we hope that history will not repeat itself, but that we have in these processes the beginning of a new and important industry. In the application of electricity to any industry, considerable time must necessarily elapse before "the trade" will give way its prejudices against a new process, and when, as in this case, there are alternative schemes before the public, the delay is likely to be prolonged by litigation. We believe that both processes are capable of yielding a valuable commercial leather, and that the manufacturers who adopt the new method will find that there are many advantages both in time, labour, and space over the older methods of tanning.

THE MANUFACTURE OF ALUMINIUM BY THE "HEROULT" PROCESS.

Some time ago (see *Industries*, Vol. V., page 406) we gave an illustrated description of the works of the Swiss Metallurgical Company at Neuhausen, where the Heroult process for the production of aluminium was first carried out on a large scale. The same process is now successfully established at Froges (Isère), near Grenoble, where it has been developed by the Société Electro-Metallurgique Française. At Froges, as at Neuhausen, hydraulic power is employed for driving the dynamos. The available supply is equal to 800 h.p., and is partly utilised by two turbines of 300 h.p. each, and a smaller one of 100 h.p. The dynamos are four in number, each yielding 6,000 amperes of 15 volts, and are worked by the two large turbines. The small turbine furnishes a current of 500 amperes, with a voltage of 65, which is employed for the lighting of the works and the motive power required for ventilating the foundry and working the smaller machinery.

In the illustrations, for which we are indebted to *Le Génie Civil*, Fig. 1 gives a general view of the crucibles in which the fusion and electrolysis of the alumina takes place. Fig. 2 shows the apparatus which is employed for the preparation of pure aluminium. The crucible is raised on isolating supports, and is lined entirely with charcoal. The negative electrode is made of metal, and fixed at the bottom of the crucible, while the positive electrode of carbon is introduced from the top and is capable of being raised or lowered into the molten alumina. The crucible is first charged with a small quantity of cryolite, which soon fuses and allows the current to pass, when electrolysis at once commences,

MANUFACTURE OF ALUMINIUM

By the "Heroult" Process at Froges, near Grenoble, France.

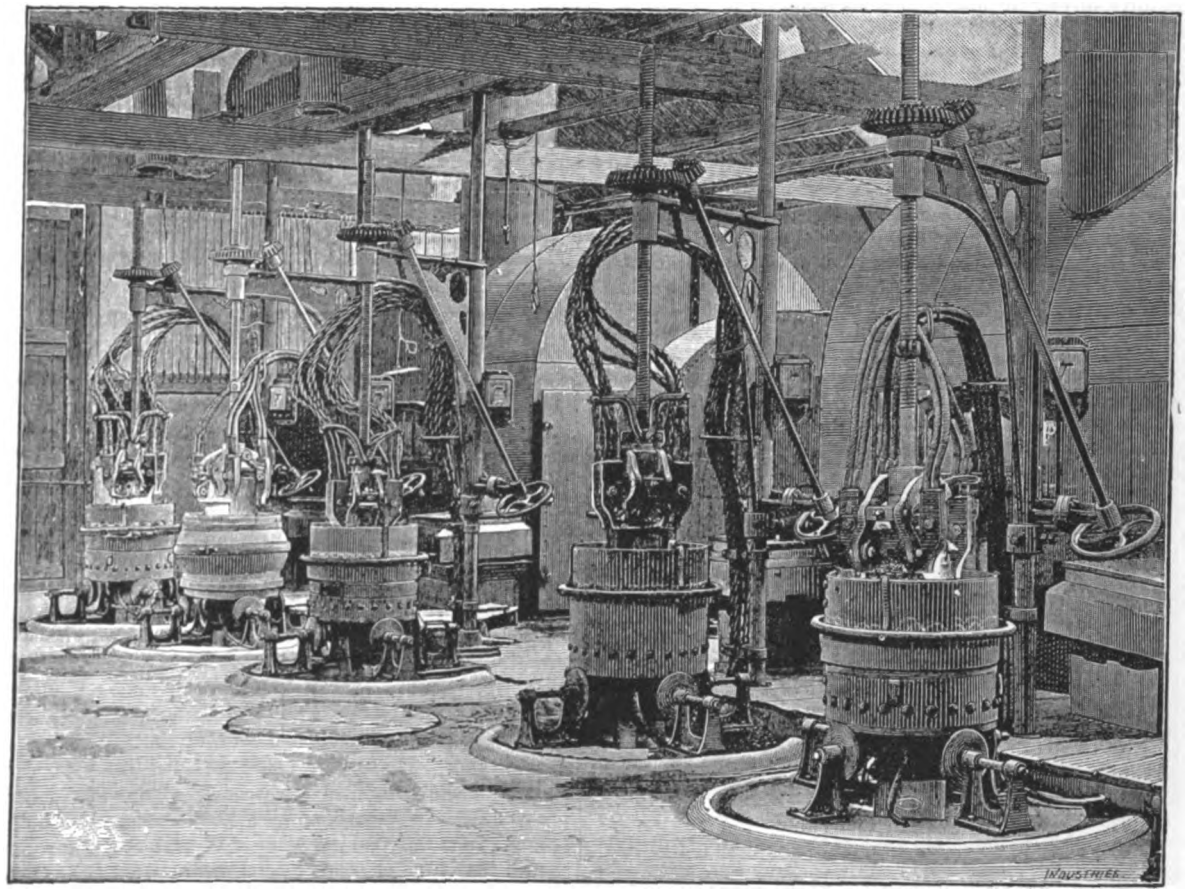

Fig. 1.—General View.

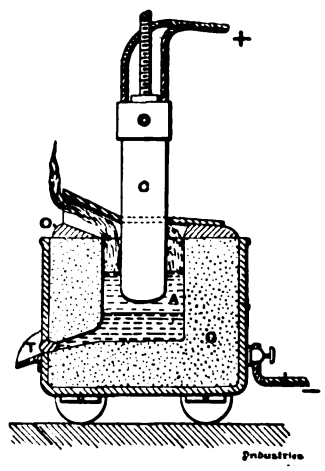

Fig. 3.

and the alumina can then be added from time to time. The metal accumulates at the bottom of the crucible, and is run off every twenty-four hours. When pure materials are used, the product is chemically pure, but in practice the percentage of aluminium in the casting varies from 97·5 to 99 per cent. For the preparation of ferro-aluminium and aluminium bronze a somewhat different arrangement is employed, which is shown in Fig. 3. Here, as in the other apparatus, the positive reducing anode is made of charcoal, and is movable. It consists of a series of plates of carbon bound together by copper bands so as to form a solid block about 1 metre in length, with a square base of ·25 by ·25 m. At C is shown the bottom of the crucible which contains the iron or copper A, which is gradually converted into alloy by the aluminium as it is produced. The opening in the side of the crucible at O serves to introduce the alumina from time to time and the metal to be alloyed. From it also issues the carbonic acid found in the reaction. At T is a plug of charcoal, closing an opening from which the molten alloy is run at the end of the operation. In working with this plant the current passes from the electrode C to the iron or copper, and is thus compelled to pass through the layer of alumina. This offers considerable resistance to the passage of the current, resulting in such an elevation of temperature that the alumina is fused to a perfectly fluid liquid, and is then capable of behaving as a simple electrolyte. The aluminium liberated alloys with the copper or iron, forming the negative electrode, and the oxygen disengaged at C rapidly burns up the carbon, forming carbonic acid, which issues from the opening O. This rapid burning away of the carbon electrode necessitates its frequent renewal, but the temperature at A is so high that all other materials are at once melted and thereby rendered unsuitable. The alloys obtained in this way contain from 8–30 per cent. of aluminium, and the yield of aluminium is approximately equal to 16 grammes per horse-power per hour. By substituting silica for alumina, the same plant can be employed for the preparation of a copper rich in silicon, from which the different silicon bronzes can be subsequently manufactured.

THE SOCIETY OF CHEMICAL INDUSTRY.

GLASGOW AND SCOTTISH SECTION.

On the 6th inst. Mr. George McRoberts contributed a paper on "Blasting Gelatine and some other Explosive Mixtures." Blasting gelatine contains 92 to 93 per cent. of nitro-glycerine and 7 or 8 per cent. of nitro-cotton, and has a similar composition to the smokeless powder patented by Sir Frederick Abel and Professor Dewar, and named "cordite." This smokeless powder had been adopted by Her Majesty's Government for use in the British army and navy. Several advantages were claimed for it. It gives an initial velocity in rifled muskets of about 2,000ft. per second, while the pressure within the barrel of the gun was less than that produced by ordinary black powder, and it is unacted upon by water. If these results were borne out there could be little doubt that a great future was in store for it, and that it would entirely supersede black powder both for the purposes of war and sport.

Dr. J. B. Readman continued his paper on "The Manufacture of Phosphorus," in which he pointed out that the present process was open to many objections, and was one which resulted in much loss of material. With these and other disadvantageous facts before him, he initiated some years ago a series of experiments to ascertain if a simpler and cheaper process of producing phosphorus could be found, dispensing with the use of sulphuric acid and also with the employment of retorts.

Notes.

TURKISH ARTILLERY.

A number of steel breechloading rifled cannons made from steel manufactured in the Turkish Arsenal have lately been put to severe tests at the proof ground on the plains of Hademkieu, which is a two hours' run from Constantinople on the Roumelian Railway. The guns consisted of a number of B. L. mountain guns on the Broadwell principle, an 8-centimetre B. L. Broadwell system, an 8-centimetre built up B. L. on the Krupp system. The mountain guns were shown to be quite satisfactory. 1,000 rounds were fired from the 8-centimetre Broadwell system, with full charges, and 1,025 rounds were fired from the 8-centimetre on the Krupp system. After firing, they were returned to the factories for examination and to be gauged. The Commission now report that after these severe tests there is no appreciable enlargement or any scoring in the bores or powder chambers, and they are considered excellent samples of modern artillery. A 12-centimetre B. L., built up on the Krupp system, is now approaching completion, and will be ready for proof in a few days. The guns have been finished and built up in the Imperial Ottoman Gun Factories with the Turkish military labour, under the personal and able superintendence of Colonel William V. Shelton and Colonel B. Atkinson.

TERCENTENARY OF THE MICROSCOPE.

The magnifying power of lenses was known from a very early date. Layard found a convex lens among the ruins of the palace of Nimrod, and there can be little doubt that the delicate carving on ancient gems owes much of its perfection to the use of magnifiers. Roger Bacon described the magnifying power of spherical segments of glass, and shortly afterwards spectacles are said to have been invented by an Italian optician. But it was not till the year 1590 that the idea of combining lenses and forming a microscope was carried out. This was done in that year by Hans Zansz or Jansen, and his son Zacharias, spectacle makers, at Middelburg, in Holland. The present year, therefore, brings us to the tercentary of the discovery, and the people of Antwerp have determined to celebrate the occasion with an International Microscopical Exhibition, in which the history and development and present condition of the instrument will be fully illustrated. The occasion will, no doubt, bring together a remarkable collection of instruments which are very interesting from a historical point of view, and others which represent the highest pitch of perfection in design and workmanship.

MINING ACCIDENTS IN 1889.

From advance summaries of the Reports of her Majesty's Inspectors of Mines we learn that the death roll for last year was longer than it has been for some years, containing as it does 1,128 names. The figures for 1888 were 960; for 1887, 1,051; and for 1886, 1,018. During last year there were ten fatal explosions of firedamp, involving the loss of 128 lives. In the previous year the deaths from the same cause only numbered 43, which accounts for an increase of 85, and the remainder must be attributed to minor casualties. These figures refer to all the mines in the kingdom, and when we examine the details of the figures we find that the increase was due entirely to accidents in coal mines, the fatalities in metalliferous mines being rather under the average. The increase is no doubt accounted for by the exceptionally busy year, and possibly a want of due care in consequence thereof. In the coal mines there were 848 fatal accidents and 1,064 deaths during last year, the number of accidents being 27 more, and the number of deaths 176 more than in the preceding year. One death occurred for every 530 persons employed, or, to put it another way, one life was sacrificed for every 178,227 tons of coal brought to the surface, as compared with one life for every 205,698 tons during 1888.

ANOTHER PROPOSED LABOUR CONFERENCE.

The Emperor of Germany seems determined to upset all preconceived notions regarding Imperial or Governmental ways of doing work. The recent Labour Conference at Berlin was an altogether novel step, but now it is reported that the Emperor proposes to summon delegates from all the trades of Germany, and that from among them he will choose the ablest to form an Operatives' Privy Council. Each member of that council, which will advise his Majesty on trade questions and assist him in controlling the working classes, will receive £100 a year and the title of Arbeitsrath. We give the Emperor credit for good intentions, but we are afraid that he is inclined to push matters too hurriedly, and we very much doubt whether such a council would have much weight with the working classes, who in their present temper would be very much inclined to look with suspicion on men who had become practically Government officials. We further doubt whether the best men, and those who were likely to do any good, would accept the position. We are of opinion that more good is likely to come from the free association of employers and employed than from any such official organisation as has been proposed.

PATERSON'S ELECTRIC TARGETS.

A new electric target system is being introduced by the Electric and Self-Indicating Target Company, of 9, Bucklersbury. The system consists essentially of two parts, one being the electric target, and the other the electric registering apparatus. The principle of the invention is as follows:—On a bullet striking the target, which is built up in sections having springs at their back, the particular section hit is forced back, together with its corresponding spring, by the force of the impact. The spring strikes a vertical lever, and causes it to fall into a horizontal position. By this means electrical communication is established through contacts and a battery with the registering apparatus placed at the firing end of the range. The registering apparatus has pointers or plates which are caused to appear behind a vertical slot, and according as one section of the target is struck by the bullet its corresponding indicator is caused to travel behind the slot, thus showing to the marksman where his bullet has taken effect. An electric bell is simultaneously rung. To interrupt the circuit and stop the bell a cord is pulled, a brush rises over the face of the target, removing the bullet splashes, and the lever is restored to its original position. A mechanical target on the spring system is also made by the firm.

BRASS WORK AND ARMS.

Although the City Companies occasionally receive a good deal of abuse, they frequently do some service to the industries they represent. The Armourers and Braziers' Company, for instance, lately offered prizes for armour and articles in brass bronze, and metals combined with brass, with a view to encourage artisans to turn out ornamental work. The Company used to exercise something like absolute powers over the production and sale, within five miles of the City, of arms, armour, and hammered brass and copper work. This control has, of course, ceased, but the Company has always been in touch with its trades. The articles submitted to the Company in connection with the competition were placed on view at the Hall of the Company in Coleman Street, E.C., on Tuesday last, and the Exhibition will close to-morrow. Most of the work is of excellent design and workmanship. It is well worth inspection, and electric light engineers will find some exceptionally tasteful electroliers, among which one in nickel and brass for five glow lamps carries off the palm. It has been designed by Mr. C. H. Mason, and carried out by Messrs. J. Longstaff and H. Ross, in the employment of Messrs. Strode & Co. The articles shown are of a very diversified nature, and include fire screens, clock cases, gas and oil brackets, *repoussé* work, a large picture frame in copper (by Mr. Holman Hunt), swords, hunting knives, and so on. It was intended to ask for exhibits from India, but time did not allow thereof. Instead, the South Kensington Exhibition authorities send a large collection of Indian work. The Company desire to exert an influence towards procuring better arms for our soldiers, and to bring about a more artistic and useful treatment of the brass and copper work, which is again becoming popular. In this they appear to be succeeding.

NAPHTHALENE AS A CAMPHOR SUBSTITUTE.

The *Oil, Paint, and Drug Reporter* points out that the extreme scarcity and high price of camphor in America has induced two or three American firms to place on the market a highly refined naphthalene suitable for the preservation of woollens, furs, and other articles from the destructiveness of insects. The naphthalene is produced in several forms, the more saleable being balls, tablets, scales, and granulated. As American coal is not so rich in naphthalene as the English varieties, our manufacturers will still supply the bulk of the crude article.

IMPROVEMENT OF THE PORT OF HOLYHEAD.

At a recent meeting of the Holyhead Local Board the offer of the London and North-Western Railway to the Board of Trade, to undertake the removal of the Platters Rocks, was considered. These rocks occupy an acre in extent, and are in a most dangerous position, depriving large vessels of the advantages of the shelter of the inner harbour. The London and North-Western Railway Company, which is very desirous of developing Holyhead, offered to remove the rocks to a depth of 25ft. at low water at a cost of half a million of money if the Board of Trade will permit the company to construct a deep water quay in another portion of the harbour, and extend their lease of their present works. The projected improvements would enable Holyhead to become a port of call for American liners, and prove a great advantage to the shipping trade. The Board of Trade, however, for reasons which were not known, had declined the offer of the railway company, but it was resolved to bring the matter before Parliament and to urge the Government to reconsider the matter.

THE LONDON POLYTECHNICS.

The Education Department has approved the scheme of the Charity Commissioners for dealing with the City of London Parochial Charities under the Act of 1883. The Commissioners propose to establish a City parochial foundation, to be administered by a central governing body of twenty-one members. The property is divided into two funds—the first to be devoted to the establishment of parks and open spaces and polytechnics, and the second to ecclesiastical purposes. The grants to institutions are:—Bishopsgate Institution, £40,000; Cripplegate Institution, £40,000; Regent Street Polytechnic, building grant, £4,000; ditto, by taking over the West London School of Art, £1,000; ditto, temporary maintenance grant, £6,750; People's Palace, £6,750; City Polytechnic (including the Northampton Institute, the Birkbeck Institute, and the City of London College), £51,000; Victoria Hall and Morley College, £6,000. The following annual payments are also proposed to be made:—Bishopsgate Institute, such a sum as, in conjunction with the residuary income of the Bishopsgate charities, will make up £2,000 a year; Regent Street Polytechnic, £3,500; People's Palace, £3,500; City Polytechnic, £5,350; Victoria Hall and Morley College, £1,000; Borough Road or Ironmongers' Institute, £2,500; Battersea Polytechnic, £2,500; South-Western Polytechnic, Chelsea, £1,500; the Joint Committee of the Working Men's College, Great Ormond Street, and the College for Men and Women, Queen's Square, Bloomsbury, £400; Bow and Bromley Institute, £150; Aldenham Institute, £150; and various other smaller sums to other Institutes, which are left to the discretion of the governing body.

Patent Record.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

5th May, 1890.

6899. Walker, W. ..... Expansion gear.
6903. London, J. A. ..... Machine for opening peat fibres.
6906. Dewar, W. ..... Guard for tramcars.
6908. Scholes & Walkden ... Looms.
6909. Riley, J. ..... Sleepers for railways.
6910. Dorrington & Coates... Gas engines.
6911. Hooper, H. W. ..... Iron and steel horse roughs.
6912. Fielding, J. ..... Gas engines.
6914. Fawcett, T. C. ..... Machinery for making bricks.
6915. Furnival & Clarke ... Book-backing machines.
6919. Holborow, H. G. ..... Engines for compressing fluids.
6928. Martyn, S. E. ..... Air compressors.
6938. Woodroffe, F. K. ..... Mills for grinding grain.
6941. Haddan, H. J. ..... Delivering condensed water free from surface scum (*Bison*).

6th May, 1890.

6951. Kellner, C. ..... Paper pulp boilers.
6955. Draper, Holmgren, Mount, & Barnes ... Removing and preventing incrustations in steam boilers.
6960. Neill, J. ..... Steel plated ingots.
6962. Ashberry & Barnes ... Mechanical clippers for sheep.
6963. Davage & Taylor ..... Manufacture of projectiles.
6972. Rouchetti & Cross ..... Fire-extinguishing apparatus.
6976. Pullen, T. M. ..... Looms for piled fabrics.
6978. Willcox & Whitehead Feeding printing presses.
6983. Bosshardt, F. ..... Cigarette making machines (*Enghien*).
6987. Tolladay, R. ..... Force pumps.
6990. Butler, E. ..... Petroleum engines.
6991. Dunn, Paterson, Riley, & Wilding ..... Cotton opening machines.
7000. Schmidt, L. ..... Drill grinding apparatus.
7001. Longsdon, A. ..... Hydraulic brakes for ordnance (*Krupp*).
7004. Nevius, J. H. ..... Hot-air furnaces.
7007. Henderson, C. ..... Boat disengaging gear.
7008. Askham & Wilson ..... Machines for making moulds.
7009. Askham & Wilson ..... Disintegrating apparatus.
7011. Fitzpatrick, H. D. ..... Grinding machines (*Lawles*).
7013. Jörgensen, J. ..... Lubrication of shafting.
7014. Wardle, W. W. ..... Rotary pump.
7015. Hill, J. ..... Automatic fire extinguishers.
7020. Fraser, Tavernier, & Casper ..... Indicator for steam engines.
7021. Lich, M. L. H. ..... Grinding machinery.
7026. Thompson, W. P. ..... Split pulleys (*Reeves Pulley Company*).
7029. Thompson, W. P. ..... Spinning machinery (*Jones*).
7031. Weiss, R. ..... Embroidery machines.
7034. Ermold, E. ..... Bottle-corking machines.
7035. Hayton, J. ..... Converting reciprocating into rotary motion.
7037. Stern, E. ..... Dynamite projectiles.
7041. Campbell, J. H. ..... Ammonia engines.
7042. Price, J. M. ..... Street railways.
7043. Lake, H. H. ..... Firearms (*Bofors Gullspang Company, Ld.*).
7046. Pogson, J. ..... Safety guards for tramcars.
7047. Speicher, J. ..... Railway joints.
7048. Whieldon, J. H. ..... Rotary measuring apparatus.
7049. Schulder, C. ..... Looms.
7050. Pitt, S. ..... Fish plates and chairs (*Weber*).
7051. Morris, H. B. ..... Looms.
7052. Kiddier, Kiddier, & Kiddier ..... Warp knitting machines.

7th May, 1890.

7061. Middleton, H. ..... War vessels.
7062. Wild, J. ..... Friction clutches.
7065. Blamires & Blamires ... Sounding and signalling apparatus.
7067. White, T. W. ..... Reducing the pitching of ships at sea.
7068. Foster, F. ..... Bottling apparatus.
7070. Heaton & Holden ..... Steel and iron.
7074. Wilson, A. ..... Self-locking safety bolt.
7083. Fairbairn, C. ..... Forging projectiles, &c.
7095. Westley, W. ..... Ring spinning machines.
7099. McTear, B. F. ..... Kilns for burning bricks.
7100. Lodge & Littlewood ... Looms.
7101. Gregory & Gregory ... Machinery for lasting boots.
7102. Pogson, J. ..... Sole plate for rail joints.
7105. Lord, W. T. ..... Steam engines.
7108. Bayly, J. P. ..... Nut lock (*Conway*).
7110. Bayly, J. P. ..... Harrow (*Mack*).
7114. Bayly, J. P. ..... Spring-actuated motor (*Dillon*).
7115. Astbury, J. ..... Ordnance.
7116. Astbury, J. ..... Breechloading guns.
7121. Ruffles, R. G. ..... Steam generators.
7129. Danton, J. D. ..... Iron.
7135. Thomson & Haigh ..... Carding engines.
7136. Henn, E. ..... Heating apparatus.
7141. Marshall & Wigram ... Slide valves.
7143. Moss & Hunt ..... Sewing machines.

8th May, 1890.

7145. Rylands, D. ..... Machinery for the manufacture of bottles.
7146. Stuart & Binney ..... Hydrocarbon engines.
7147. Bradbury, W. ..... Mules.
7149. Braithwaite, C. C. ..... Fluid pressure engines.
7151. Tucker, J. ..... Grain elevators.
7154. Wilkinson & Wilkinson Jacquard mechanism for looms.
7157. Wilson, J. ..... Appliances for shafting hammers.
7162. Hardie, T. G. ..... Boiler furnaces.
7163. Partington, E. ..... Paper refining engines.
7164. Mackay, F. N. ..... Grain conveyors.
7165. Mackay, F. N. ..... Apparatus for drying sludge.
7167. Morison, D. B. ..... Feed heaters.
7169. Duggleby, S. ..... Sifting machines.
7171. Schmidt, F. T. ..... Parallel vice.
7172. Carruthers, J. H. ..... Pumps.
7176. Greaves, W. McG. ..... Furnaces.
7177. Mewburn, J. C. ..... Combined gas and compressed air motors (*Proell, Kummer, & Fischinger*).
7179. Coram, J. C. ..... Machines for finishing tubes.
7187. Church, W. C. ..... Slide valves.
7192. Pringle, T. ..... Ships.
7197. Younghusband, S. S. ... Slide valve.
7201. Lorrain, J. G. ..... Forging metals.
7210. Pitt, S. ..... Steam heating apparatus (*Kieley*).

9th May, 1890.

7212. Newcome, H. J. ..... Elevator.
7214. Popplewell, T. ..... Rag-breaking machines.
7226. Thompson, W. ..... Prevention of collisions at sea.
7233. Parkinson, G. S. ..... Pneumatic propulsion of trains.
7234. Lea, E. C. ..... Sewing machines.
7241. Mossop, J. A. ..... Clipping machines.
7245. Haddon & Slade ..... Firearms.
7253. Hodge, W. ..... Converting iron into steel.

10th May, 1890.

7262. Tarbet & McDonald ... Sewing machines.
7263. Thomas, F. ..... Railway carriage coupling.
7264. Stones & Stones ..... Expansion valve.
7265. Edge, J. ..... Middlings purifiers.
7266. Kohl, A. ..... Alarm indicator for boilers.
7273. Hingelberg, G. R. ..... Diminution of air resistance of trains.
7274. Rivret & Colson ..... Carding machines.
7275. O'Donnell, Smith, & Timmis ..... Railway signalling apparatus.
7279. Shorrock, Hacking, & Feilden ..... Looms.
7282. Ambler, W. ..... Moulding tubular articles from molten metal.
7285. Lake, H. H. ..... Railway joints (*Continuous Rail-joint Company*).
7288. Downing, G. C. ..... Bench vice (*Sonty*).
7291. Paterson, J. M. ..... Marine boilers.
7294. Thompson, W. P. ..... Mortising and boring machines (*Young*).
7297. Frances, D. ..... Continuous brake.
7300. Bradford, T. ..... Ironing machines.
7303. Wanner & Rebmann ... Lubricating apparatus.
7304. Imray, O. ..... Machine gearing and couplings (*Mannesmann*).
7308. Robinson, J. ..... Steam boilers.
7312. Baudry-Diot, E. ..... Bridges.
7318. Bayly, J. P. ..... Drainage and sewerage system (*Hallock*).
7319-20-21. Bayly, J. P. ..... Buoyant propeller and water locomotive (*Pond*).
7324. Rivett, T. ..... Winding yarns.

ELECTRICITY.

5th May, 1890.

6924. Eagar & Milburn ..... Batteries.
6933. Von Peichl, J. ..... Mariners' compasses.
6939. Crawcour, W. H. ..... Telegraph and telephone wires
6943. Fischinger, E. ..... Arc lamps.
6945. Appleton, J. ..... Electric switch.

6th May, 1890.

7003. Duncan & Carpenter... Electric motors.
7044. Lake, H. H. ..... Conduits for electric conductors (*Brooks*).

7th May, 1890.

7125. Romanze, Weise, & White ..... Electricity meters and clocks.
7132. Lake, H. H. ..... Carbon electrodes (*Lacombe & Cie.*).

8th May, 1890.

7185-6. Thompson, W. P. ..... Electric welding (*Coffin*).
7196. Grefen, H. ..... Electric door lock.
7209. Saunderson, L. ..... Arc lighting. (4th December, 1889.)

9th May, 1890.

7219. Perry, J. ..... Electric supply meter.
7225. Baker, T. J. ..... Electric bell pushes.
7239. Woolley & Hunnex..... Electric switch.

CHEMISTRY.

5th May, 1890.

6931-2. Abel, C. D. ..... Colouring matters.
6936. Bamberg, G. ..... Extraction of gold.
6946. Pitt, S. ..... Colouring matters (*Cassella & Co.*).

6th May, 1890.

7018. Cole, W. ..... Indigo.
7019. Serre, C. A. ..... Soap.
7055. Sinclair, A. ..... Copper ores.
7058. John, J. Y. ..... Chlorine (*Marx & Weller*).

7th May, 1890.

7063. Fourness, H. ..... Water gas.
7117. Scott, H. ..... Soap.

9th May, 1890.

7247. Baudouin & Escarpit... Ammonia.
7252. Lindsay, R. C. ..... Illuminating gas.

10th May, 1890.

7260. D'Andria, M. N. ..... Oxide of iron pigments.
7277. Cruikshank, G. M. ..... Manufacture of gas (*Reissig, Landin, & Maccallum*).
7301. Lundholm & Hosie ..... Explosives.

MISCELLANEOUS.

5th May, 1890.

6905. Moore, F. W. ..... Non-conducting covering for steam pipes.
6940. Wood, E. T. ..... Hollow balls of celluloid. (9th November, 1889.)

6th May, 1890.

6952. Kellner, C. ..... Coating iron with Portland cement.
6982. Fleming, F. ..... Carding fibres.
6993. Kellner, C. ..... Manufacture of paper pulp.
6998. Taylor, I. F. ..... Fog signalling apparatus.
6999. Lancaster, W. J. ..... Levels.
7038. Lake, H. H. ..... Mechanical telephones (*Knight*).

7th May, 1890.

7075. Hunt & Mackey ..... Filtering apparatus.
7076. Morris, R. ..... Cartridges.
7138. Lawrence, W. ..... Softening water.
7142. Stern, H. ..... Decolorising oils.

8th May, 1890.

7198. Spencer, W. H. ..... Bleaching textile fibres.
7202. Cavailles, P. ..... Dyeing wool.

9th May, 1890.

7238. De Liebhaler, L. E. A E. D. ..... Removing rust from iron.

10th May, 1890.

7270. Challinor, C. ..... Fog signalling.
7314. Benners, E. H. ..... Grease cups.
7327. Thompson, F. O. ..... Pots for melting glass.

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given, give notice at the Patent Office, in the prescribed form of such opposition.

Year 1889.

1115. Chapman.
7488. Harrison.
7758. Peyman.
7894. Atkinson.
8097. Hart & Baynes.
8296. Wall.
8600. White & Carson.
8676. Wasserman.
8916. Milne.

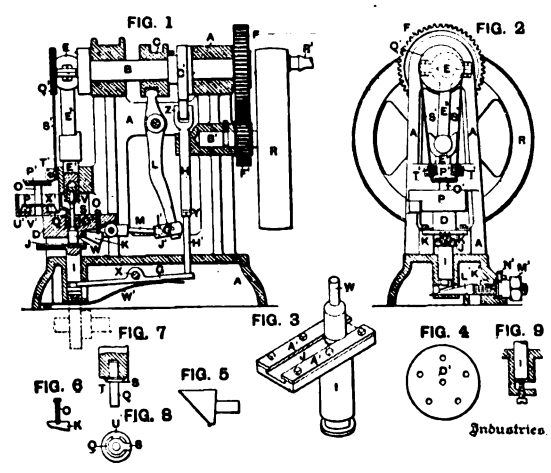
ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

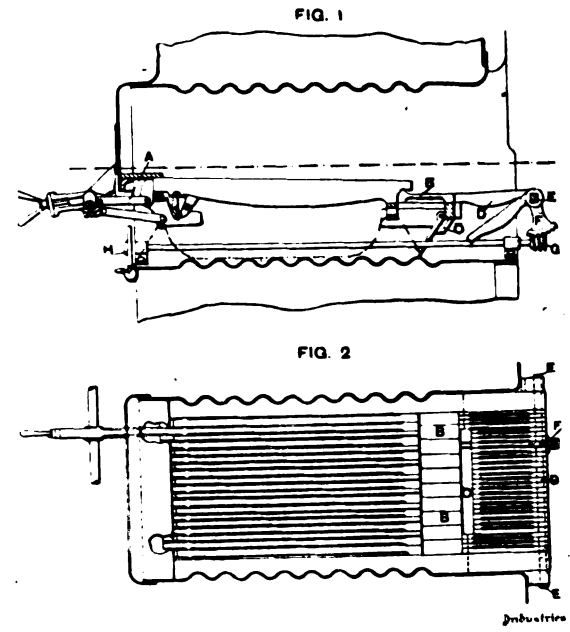


Restarting Tramcars, &c.—*E. Dredge, London.*—In this class of mechanism the power exerted to stop the tramcar is utilised for the purpose of restarting it. Combined with the starting mechanism in this invention is a brake which is pressed against the wheels by the impetus of the car. In the accompanying illustrations Fig. 1 is a longitudinal section of the tramcar, Fig. 2 an underside plan, Fig. 3 a transverse section on X X, and Figs. 4 and 5 details. On the axle B is a clutch E E¹, worked by means of the connections F G H and I, which are under the control of the driver. Connected to the drum of the clutch by the chains J is an open link chain C. The other end of the link chain C is secured to a crosshead D sliding upon the guide rods K. The chain also passes between two guide pulleys L. To the back of the crosshead D are attached rubber springs M. Upon the second axle A is a loose chain wheel N, having a ratchet wheel O upon one side as illustrated in Fig. 5. The ratchet wheel O is keyed to the shaft. The driver, when desiring to stop the car, throws the clutch E E¹ into gear, and causes the drum to wind up the chains J under the influence of the momentum of the car. The link chain C is thus drawn out, and the springs M distended. As the chain C is drawn out it engages with the teeth of the wheel N, and revolves it upon the shaft until it ultimately assumes the position shown by the dotted lines. To start the car the driver releases the clutch E E¹, and the springs will pull back the chain C. This will cause the wheel N, with which the chain is in gear, to rotate in the direction in which the car is to proceed, and, by reason of the pawl and ratchet arrangement, it will also drive the axle A in the same direction, and so propel the car. In pulling out the chain C during the stopping of the car, the crosshead D will strike against and push forward another crosshead P, which may also slide on the guide rods K, and is attached by a chain Q to the chain of the ordinary brake lever R. Thus it will be seen that the act of storing the power during the stopping of the car will also put on the brakes, and as the power is produced by the impetus of the car the action of the brakes will be more powerful than when worked by the driver. Claims: (1) In car-starting apparatus the combination of a friction clutch on one axle, with an open

link chain which is drawn out (against the tension of a spring or otherwise) by a drum on the said clutch, and a silent clutch or pawl and ratchet coupling on the other axle, as and for the purpose set forth; (2) the arrangement of car-starting apparatus, as herein shown and described; (3) the combination with a car-starting apparatus of a brake mechanism, whereby the momentum of the vehicle which is used to set the starting mechanism serves also to actuate the brake mechanism as set forth; (4) the arrangement of car-starting apparatus herein shown and described in combination with the ordinary brake mechanism of tramcars.—No. 14,986. September 23rd, 1889. 8*d*.

Steam Traps.—*J. Coulong, Hollin Bank, Blackburn.*—In a closed vessel provided with inlet for condensed steam and outlet for discharge of water is pivoted a bell-crank lever. To one arm is attached a ball float and to the other an adjustable weight. On the ball float arm and at a short distance from its pivot is attached a valve of the double beat type, the seatings being equal in diameter top and bottom. The arm carrying the weight is set vertically and the arm carrying the float horizontally when in the position ready for discharging water. When the steam and water enters the vessel the ball float rises, and, by lifting the double beat valve, opens it, permitting the water to escape. When the water again sinks to the normal level the lever and valve assume their previous positions The weight upon the arm keeps the valve tightly closed. Three claims are made.—No. 8561. May 23rd, 1889. 8*d*.

Compressing Machines.—*J. A. McFerran, Philadelphia, U.S.A.*—The machine is for compressing pulverised materials into the form of pills or tablets. Fig. 1 is a sectional side elevation of the machine, Fig. 2 an end elevation, and the remaining figures represent details. The die carrier D is oscillated by a cam C on the driving shaft B through the medium of the lever L. The compression die Q is carried by a plunger E¹ which is given a vertical reciprocating motion by the crank E. Adapted to the lower die is an ejector W operated by the eccentric C¹, lever G, and rod H. The hopper P is fitted with a stirrer U¹ which is revolved by the endless band S¹ driven by the pulley Q¹ fixed to

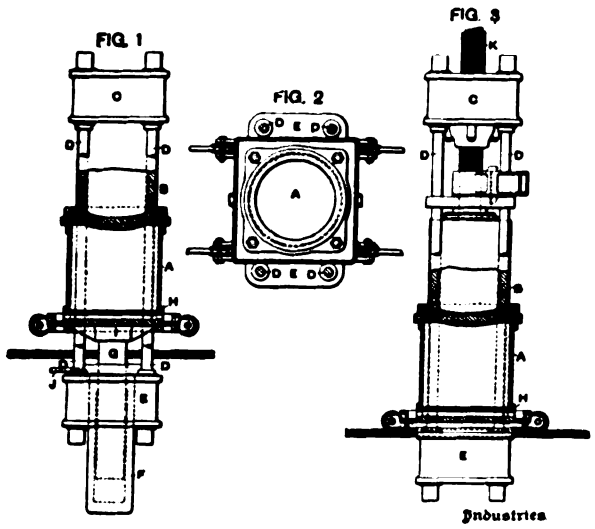


the pin of the crank E. Beneath the post I is a wedge-shaped adjustable block N by which the machine may be regulated for quantity. The cycle of operations is as follows:—As the driving shaft is revolved, the die carrier passes under the opening in the hopper P, thereby taking in a charge of material. The die carrier now returns to the position shown, and the compressing die Q descends, forcing the part W down until the post I rests upon its seating and the charge is properly compressed. When the top die commences to reascend the ejector comes into action and the pill formed is thrown out of the mould. Seven claims are made for the improved machine described and illustrated.—No. 5861. January 5th, 1889. (Application April 5th, 1889.) 8*d*.

Double-lift Jacquards for Looms—*W. J. Cheetham & S. Sutcliffe, Kirkstall, Leeds.*—Above both sets of knives is pivoted a clearing bar. To each clearing bar is attached a pivoted vertical lever connected to a spring hammer, having double inclined bearing surfaces working against a fixed roller. The uprights have a projection about half way of their length. These projections, when the uprights are lifted, engage with a fixed knife, which holds them up until they are required to drop. When the uprights are going down the projections are held off the knife, which is coming up by the clearing bar until they get past the centre. By this arrangement only one neck cord is required where two have been used before, and as there is no jerking of the cords they last longer. Three claims are made.—No. 9548. June 8th, 1889. 6*d*.

Bridges for Boiler Furnaces.—*T. Plant, Huntingdon.*—The bridge is constructed of several pieces, so as to permit free expansion and contraction of the parts, and at the same time provide means for the more perfect combustion of the fuel. The bridge up to the level of the fire-bars is solid, but it has pipes in it for supplying air to the upper structure. Above the level of the fire-bars the bridge is hollow. The front and back are formed of suitable bars of iron bolted upon the brick sides, so as to form together a chamber with open top. Into this chamber the pipes in the solid bottom lead and supply it with air and steam. On the top of the chamber is an adjustable plate inclined from the front to back of the furnace. In operation the flames strike the front of the chamber, and then rise and pass over the inclined plate and mouth of the chamber. The steam and air rising from the latter meets the flames and smoke, and thorough combustion ensues. Claims: (1) A fire-bridge formed of bars capable of yielding to expansion and contraction as set forth; (2) a fire-bridge having a hollow chamber surmounted by an adjustable inclined plate, into which chamber air and steam are conducted, so as to commingle and become heated therein, and meeting the gases from the flames above the chamber promote combustion of the fuel, all as described.—No. 10,994. July 8th, 1889. 6*d*.

Furnace Fire-Bars.—*T. Henderson, Liverpool.*—In former patent specifications the inventor has described forms of self-cleaning fire-bars. The present invention is an improvement upon them. The figures show respectively a longitudinal section through an elevation of the furnace, and a plan of the same. In

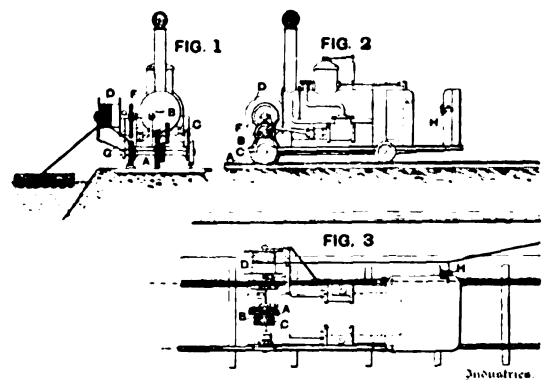


the front part of the furnace is a well-known mechanical method A of agitating the fire-bars, and causing the fuel to travel towards and over the dead-plate B, until it falls over into the ashpit at C. The present invention consists briefly in providing at the end of the furnace to which the clinkers travel a movable dead-plate, having small or no air passages. This device, termed the "clinker-plate," is mounted and arranged so that it may be tilted from time to time as desired. It is represented in the figures by D, its upper surface being a continuation of the dead-plate B. In this instance the clinker-plate is a series of fire-bars, and occupies about two-thirds of the width of the furnace. It turns about its rear end upon a shaft E, made to revolve by the toothed sector F and worm G, controlled by the hand-wheel H. Several modifications are made in the manner of working this clinker-plate. This improvement forms a ready means of discharging the clinkers from the furnace into the ashpit. Claims: (1) The arrangement within a boiler or other furnace of a tipping clinker-plate, forming a continuation of the fire-bars at either end of the furnace, and adapted to receive the clinker from the said bars, and also to discharge such clinker into the space below the bars each time it is tipped by means of suitable mechanism, operated or released from the front end of the furnace or from other convenient point, substantially as described; (2) the arrangement within a steam boiler or other furnace of a system of self-cleaning fire-bars, similar to that illustrated, only adapted to feed the fuel and clinker from the rear portion of the furnace towards the front, in combination with arrangements for quickly discharging or removing said clinker after it has reached the tail end of the fire-bars.—No. 8539. May 22nd, 1889. 8*d*.

Slide Valve Gear.—*E. M. Galloway & J. H. Beckwith, Manchester.*—The slide valve is operated by a cam fixed to the piston rod of the engine. In the groove of this cam runs a bowl mounted upon one end of a bell-crank lever, the other end of the lever being pivoted to the piston rod and the angular part of the bell-crank lever pivoted to the framing of the engine. As the piston makes its strokes the cam travels backwards and forwards, and the bowl working in the cam oscillates the bell-crank lever, and consequently works the valve. As the path of the bowl is in the shape of a rhomboid the bowl is kept against the proper face of the cam by a spring secured to a third arm of the bell-crank lever and to the reciprocating cam. This spring, as the cam reciprocates, pulls the bowl first against the top of the cam and then against the bottom, causing it to travel forward in the groove continually. Other means are shown and described for causing the bowl to travel correctly in its groove, and in a modification the cam is detached from the piston rod, but made to oscillate upon a stud by connecting it to the piston rod by a

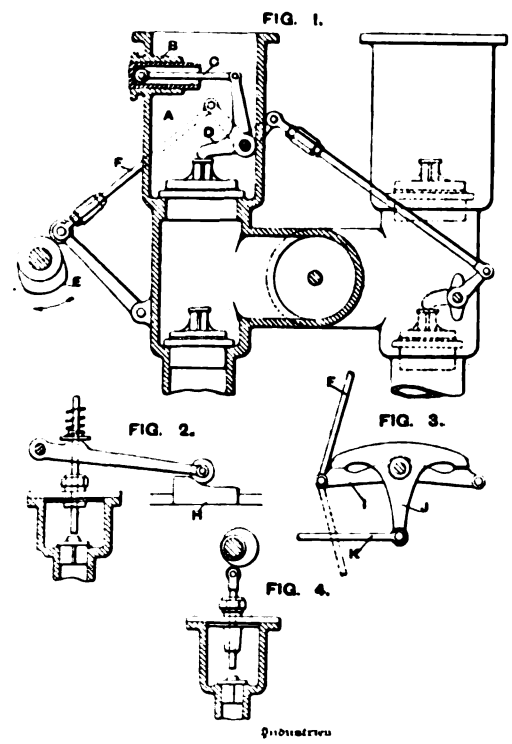
Digitized by Google

rod or link. Claims: (1) For working the slide valve of an engine or pump, the combination of a part reciprocating along with the piston and having a cam groove acting on a roller mounted on the arm of a lever linked to the slide rod as described; (2) in combination with the slide rod lever and cam groove referred to in the preceding claim, a spring or a roller pressed by the piston of a subsidiary cylinder and acting on the lever as the cam groove approaches each end of its stroke, so as to insure the complete movement of the lever as determined by the cam groove; (3) in combination with the slide rod lever and cam groove above referred to, a subsidiary cylinder having its piston connected to the slide valve of the main cylinder, and having its own slide valve worked by the reciprocating part as described.—No. 3659. March 7th, 1890. *6d.*



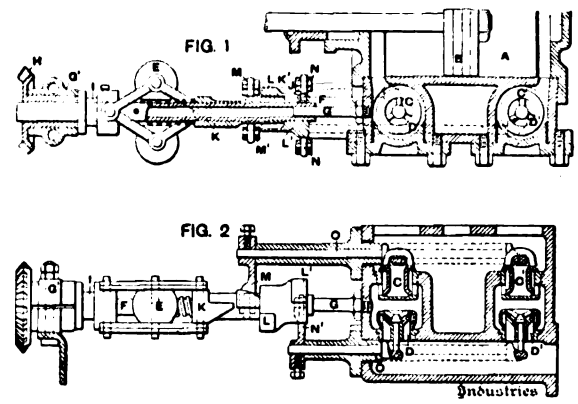
PRESSES FOR FRUIT, &c.—*R. Heaton, Malaga, Spain.*—The press described in this specification consists of a perforated vessel for the reception of the fruit, and provided with a piston or presser, which, entering the vessel, compresses the fruit. Fig. 1 is a sectional elevation of a press constructed according to the invention and adapted to be worked by hydraulic power, Fig. 2 is a plan of the same, and Fig. 3 is a sectional elevation of a similar press worked by manual instead of by hydraulic power. A is the receptacle of circular shape, whose walls and bottom are perforated. B is the piston or pressure adapted to enter the receptacle. The piston is secured to a crosshead C supported upon the standards D which are fast at their lower ends to the bed-plate E. A hydraulic cylinder F is connected to the bed-plate E, and its plunger G terminates in a head I designed to enter the recess of a carriage H. In the modification shown in Fig. 3 the presser is lowered into the receptacle by the screw K in the manner of a screw press. The operation of the apparatus is as follows:—After the receptacle is filled with the material to be pressed or squeezed, the carriage is pushed into the apparatus beneath the presser B, water under pressure is then introduced through the pipe J into the hydraulic cylinder F, whereby the plunger G is raised so as to press against the underside of the carriage and lift

the same with the receptacle towards the presser B, the upward movement being continued until the presser has entered the receptacle to a sufficient extent to produce the desired pressure. Claims: (1) Apparatus for pressing fruit, pulp, and other substances, comprising a perforated receiver which is mounted upon a carriage, a piston or presser adapted to enter the said receiver to press the materials therein, and means for moving the said receiver and the piston or presser relatively to each other; (2) the manufacture and use of the improved apparatus for pressing fruit, pulp, and other substances.—No. 3840. March 4th, 1890. *6d.*



PURIFYING WATER.—*L. A. Cheralet, Paris.*—The process is one in which the salts contained in the water is precipitated by heat. It is based upon the fact that if calcareous water be brought to boiling point the carbonic acid it contains (which acid keeps in solution the salts of lime and magnesia) is set at liberty with the steam, and the salts are thus precipitated. To entirely clear the water of calcareous matter it is necessary to keep the water at boiling point some length of time. The apparatus used for this purpose is composed of a series of vessels arranged one above the other and provided with overflow pipes leading from the upper vessel to the one immediately below it. The water to be purified is supplied to the top vessel, and descends by the overflow pipes from one vessel to the other. For heating the water to boiling point, steam is admitted to the bottom vessel, and, after percolating the water it contains, passes on up and through the water in the other vessel. The steam passes into each vessel from below through a central upright pipe whose top edge is slightly higher than the overflow pipe. Over the top of this pipe is a circular deflecting hood with serrated edges, the edges being turned downwards and submerged in the water. Thus the steam, as it passes in by the upright pipe, is deflected by the hood, and has to pass under its edges and through the water before escaping to the vessel above. When the appliance is thoroughly at work the water is kept at the boiling point in all the vessels, and the calcareous matter precipitate in them. Claims: (1) The bubbling of steam from engines in water to be purified, such bubbling to take place successively in the distilling column, modified to suit the deposition of calcareous matter; (2) the application of a box for scouring the steam by the shock of the latter against a plate without holes, in order to obtain water free from grease for the boiler; (3) the application of Mariotte's vessel to the purifying apparatus, in order to introduce the solution of carbonate of soda required when the water contains plaster; (4) the arrangement of a horizontal purifier and its application to steamboats, &c.; (5) its adaptation for heating water for steam boilers, such adaptation being intimately connected with the process of purifying water when waste steam is used for the purpose.—No. 8271. May 18th, 1889. 8d.

LOCOMOTIVES FOR TOWING PURPOSES.—*F. Koernig, Bromberg, Germany.*—The locomotive is designed for towing rafts and other vessels on rivers and canals. Fig. 1 is a front elevation, Fig. 2 a side elevation, and Fig. 3 a plan of the engine. The boiler and firebox and the steam cylinders are attached to the frame of the locomotive in the usual manner. The frame rests on two axles, each of which is provided with a toothed wheel and a plain wheel with double flanges. On the front axle there is, at the centre, a spur wheel A, into which gears a pinion B fixed on to the crank



shaft C, which is driven by the pistons. There is also a second pair of wheels, as shown, by which the crank shaft and the driving axle can be geared together to run at about the same speed. The four wheels thus constitute slow and fast speed gears. At one side of the locomotive there is journalled a rope drum D on the shaft of which is keyed a toothed wheel F which gears into a toothed wheel G mounted on the crank-shaft. The wheels F and G can be put out of gear with each other at will. The position of the drum D is such that the pull of the tow rope will not bring any appreciable lateral pressure on the toothed rail. Connected to the drum D there is a contrivance such as a calendar or mangle wheel for effecting regular winding up of the rope, as is well understood. On the rear part of the locomotive is fitted a hand crank and winch H by which the towing rope can be tightened or slackened. By this means, in cases of bends in the stream, it is possible from the locomotive to supplement the action of the rudder or entirely to effect the steering of the vessel which is being towed. Claims: (1) For towing rafts, ships, and other floating bodies, a locomotive having gearing interposed between the crank shaft and the driving axle such that the speed of the locomotive may be decreased when it is towing and increased when running light, the said locomotive running on the tow-path on a permanent way comprising a toothed rail next the waterway and a plain rail at the opposite side; (2) in a locomotive for towing rafts, ships, and other floating bodies, the combination with a driving axle having a plain double-flanged wheel running on a plain rail and a toothed wheel running on a toothed rail (the said axle being driven by fast or slow gearing from the crank-shaft), of a rope drum, driven from the engine, and designed by hauling in or paying out the rope to aid the steering of the floating body which is being towed; (3) in a locomotive of the kind referred to in claim 2 arranging the rope drum in such a position that the pull of the tow rope will not bring any appreciable lateral pressure on the toothed rail, and providing the said drum with an application such as the well-known calendar or mangle wheel for ensuring the regular winding up of the rope.—No. 5915. April 6th, 1889. 8*d.*

VALVE GEAR.—*A. Riedler, Berlin, Germany.*—The valves referred to are those used for pumps, compressers, and the like. They are operated by the motion of the piston and by the pres-

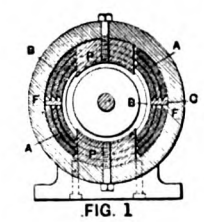
sure of liqnid in the valve chamber. In operating the valve gear of a double-acting pump as shown in Fig. 1 the constant liquid pressure within the valve chambers is utilised to weight down the valves. The piston B is, for this purpose, connected by the rod C to a bell-cranked lever D whose lower arm rests upon the top of the valve A. It will be seen that by this arrangement the force of the liquid against the inner surface of the piston B tends to keep the valve closed. This pressure is removed the instant before the valve is automatically opened. To release the pressure upon the valve a rotating cam E presses against the rod F and revolves the lever G about its spindle, to which is secured the lever D, and so the latter is raised from off the valve. The levers of two valves are coupled together as shown. A modification of the gear as described is illustrated by Fig. 2. In this case the pressure upon the valve is released by a reciprocating cam H. Fig. 3 shows a method of actuating the gears of a double-acting pump such as shown in Fig. 1. The rods F of the two sets of valves are connected to the arms of a lever I. An oscillating motion is imparted to the lever I by a T-shaped lever J whose upper arms strike the arms of the lever I as they are moved upwards and downwards by an eccentric rod K. Fig. 4 shows a form of value acted upon directly by a rotating cam. Six claims are made.—No. 14,021. September 5th, 1889. 8*d.*

ENGINE VALVE GEAR.—*S. Eddington & J. E. Stevenson, Chelmsford.*—The valves are of the double or equilibrium type, and are actuated by cams upon a shaft, to which the governor is also mounted. The cams for the admission valves are double (one for each direction of the engine); they are of a spiral form, and connected to the governors. The motion of the governors controls the extent to which the valves act. The figures show respectively a sectional plan and elevation of the gear. A is the cylinder, B the piston of an ordinary engine. C C^1 are the steam admission valves, and D D^1 the exhaust valves. E E are the governors carried on the hollow shaft F. The hollow shaft F is mounted in bearings G at right angles to and is driven by the crank-shaft through mitre gear H. The end of the governor nearest the crank-shaft is formed with a groove I, in which a fork engages from an ordinary reversing lever, by means of which the governors and cams can be moved with the shaft F. Attached to the opposite ends of the governors are the cams K K^1 for actuating the admission valves; these double cams are formed in one hollow block or piece sliding on the hollow shaft F. The cams L L^1 actuating the exhaust valves are, in the arrangement shown, fixed on the hollow shaft F by means of a set screw J or other device. The cams K K^1 and L L^1 actuate the admission and

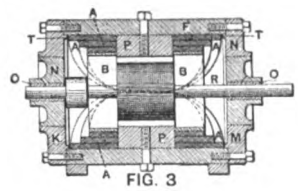
exhaust valves by means of levers M M^1 and N N^1 and cranked spindles O. The cams K^1 and L^1 are shown in gear, and in order to reverse the engine the shaft having the governors and cams mounted upon it is pushed forward by means of the reversing lever or the like, so bringing the cams K and L into gear. Claims: (1) In self-acting expansion engines constructed with equilibrium double beat or similar valves worked by cams mounting the governors and the cams actuating the admission and exhaust valves on the same shaft; (2) in engines constructed with equilibrium double beat or similar valves worked by cams arranging such cams and governors in the manner described in the foregoing specification and as illustrated for the purpose of reversing the engines; (3) the general arrangement of valve and reversing gear for engines substantially as described and illustrated.—No. 8565. May 23rd, 1889. 8*d.*

LIFTING JACK.—*J. P. Cito, Petange, & P. Funck, Luxemburg.*—This appliance is for raising railway rails and such like purposes. In a metal shoe or frame constructed with a flat bottom plate and two side plates, in shape sectors of a circle, is pivoted the raising lever. The lever is pivoted in the side plates near the apex of the sectors, and the circular portions of the sectors are made with ratchet teeth. In the long end of the raising lever is a cross-pin which engages in the teeth of the sectors as that end is lowered and holds it in the lowered position. To lower the long end of the raising lever, and consequently raise the shorter or loaded end, a loose hand lever is used provided with a circular cam head. In this head are secured eccentrically two small pins. When raising the load the pins are placed in the teeth immediately above those in which the pin of the raising lever engages. The cam face of the hand lever then rests upon the long end of the raising lever, and by pulling the hand lever over the eccentric cam face forces down the end of the raising lever until it engages in a fresh pair of teeth. The hand lever is then removed to the next pair of teeth, and the action repeated until the load is raised to the required height. Claim: An apparatus for lifting weights characterised by a lifting lever pivoted in a bottom frame upon its free end acting the eccentric cam of a hand lever to be placed in different notches of the frame in accordance with the height to which the weight is raised, whilst with the lifting lever is connected a link which in every case keeps the weight raised by means of its pin placed between the bent locking arm pivoted to the frame and arranged eccentrically to the pivot of the said lifting lever, the said link preventing the back movement of the arm and of the lifting lever.—No. 2704. February 19th, 1890. *6d.*

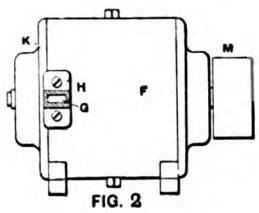
FURNACES.—*E. F. Paddon, London.*—All kinds of furnaces are referred to, the novelty in construction being the use of a perforated plate at the charging end of the furnace. The plate is a prolongation of the dead-plate, and is slightly inclined downwards towards the fire-bars. Under the perforated plate in the ashpit is a deflecting plate to cause air entering the ashpit to be directed upwards through the perforations into the furnace and over the fuel, thus forming a complete combustion. Claim: In furnaces the combination of a perforated plate with a plate or feather inclining downwards into the ashpit to divert the draught up through the perforations into the furnace as described.—No. 3591. March 6th, 1890. *6d.*



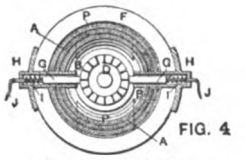
Digitized by Google



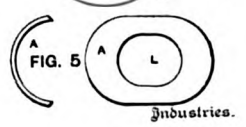
WATER HEATERS.—*E. Werdenberg, Bâle, Switzerland.*—According to the invention two concentric tubes, each formed with hollow walls and communicating with each other at the top and bottom, are placed vertically. The outer tube is curved over at its upper part to form a cap, and its lower end is enlarged so as to contain a greater body of water than the other parts. A space is left between the two tubes, and inside the smaller one is a flue pipe leading out at the top. Gas burners are placed on the lower part of the apparatus, and the heated products from these pass upwards between the two tubes, and then downwards within the smaller tube, and, finally, up again through the flue pipe away. The gas burners are Bunsen burners, and are arranged in a ring, and so that the flames strike the enlarged part of the outer tube, where is the largest body of water. Three claims are made.—No. 8864. May 28th, 1889. 8*d*.



ELECTRICITY.



COLLECTORS FOR DYNAMOS, &C.—*E. Holt, Manchester.*—The improved collector consists of a pair of wheels which rotate in contact with the commutator. The wheels are supported on the arms of a T-shaped frame mounted upon the spindle of the commutator, so that the centre of the wheels and the commutator shaft are in a straight line. The T-shaped frame can be rotated about the commutator shaft, so that the collector wheels may be placed at any angle. To permit the wheels being pressed against the commutator the wheels are flexibly connected to the frame, and a spring holds them against the commutator. The bearing blocks of the wheels are insulated from the frame, and are made elastic in order to take up the wear and form a good electrical connection. Claims: (1) The arrangement of rocker and current collector or conductor for dynamo and other electric machines as described; (2) in dynamo and other electric machines, the arrangement of two rollers pressed against the commutator by spring pressure, and rotated by contact with the bosses, or of said rollers for collecting and conducting the current from the commutator to the field magnet coils as described.—No. 19529. December 5th, 1889. 6*d*.



DYNAMO ELECTRIC GENERATORS AND MOTORS.—*G. E. Dorman, Stafford.*—A wrought or cast iron tube encloses the armature, field magnets, and other parts of the machine. The illustrations show Fig. 1 a transverse sectional view through the centre of a dynamo or motor, Fig. 2 a side view, Fig. 3 a central longitudinal section, Fig. 4 an end view with the commutator end bracket removed, and Fig. 5 views of a sectional coil of the field magnet coils. The tubular case F is closed at its ends by two covers K M, which also support the armature shaft. Around the pole pieces P are the field coils A, made for convenience in two or

FIG. 1

FIG. 3

FIG. 2

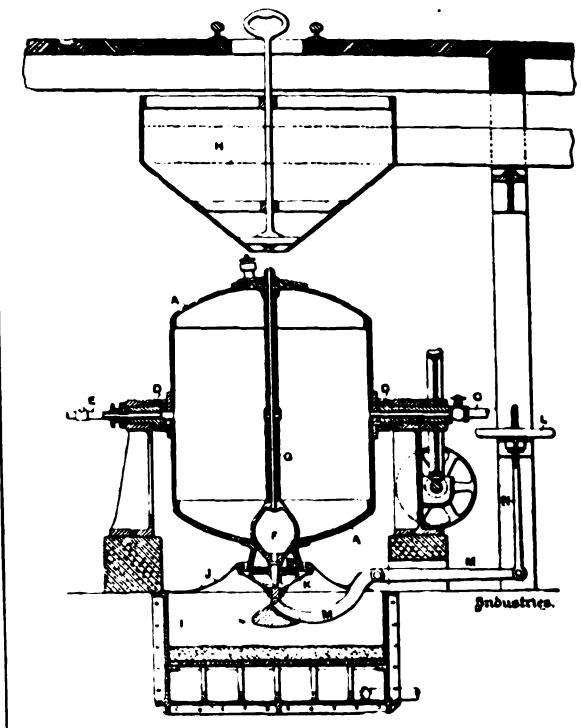
FIG. 4

FIG. 5

Industries.

more sections. The coils are first wound and taped, and then bent to the required curvature in a mould or die. The coils fill as nearly as possible the annular space between the armature and case, so as to bring them into proximity with the armature. D is the commutator, and G the brushes of the machine. The brushes G are supported in tubular cases H, having an insulating fibre sheath. In large machines an air propeller is arranged within the casing to draw in air through perforations in the pulley end cover for the purpose of cooling the interior of the machine. Claims: (1) In a dynamo electric generator or motor an iron tube, or equivalent structure, containing two interior pole pieces with field or exciting coils arranged around the said pole pieces, the coils being bent or shaped to conform with or fit the interior curvature of the said tube or equivalent structure; (2) in a dynamo electric generator or motor an iron tube, or equivalent structure, containing two interior pole pieces, with sectional field or exciting coils arranged around the said pole pieces, the said coils being bent into proximity to or to embrace the armature; (3) in a dynamo electric generator or motor an iron tube, or equivalent structure, containing two interior pole pieces, with field or exciting coils arranged around the said pole pieces, the coils being bent; (4) in a dynamo electric generator or motor an iron tube, or equivalent structure, containing two interior pole pieces, and bent exciting or field coils, with end plates or brackets completely enclosing one or both ends of the said tube.—No. 6568. April 17th, 1889. 8*d*.

ELECTRIC SWITCHES.—*F. B. Nicholson, London.*—The switch consists of a centre contact piece, turned taper and working in suitably constructed contact pieces after the manner of an ordinary gas or water taper plug tap. The contact pieces are so arranged that when the centre contact piece or plug is turned to one position the electric circuit is completed, whilst in another position it is broken. The plug is held down by a coil spring in contact with the contact pieces, and it is turned about its axis by a handle or key. Claims: (1) The construction, combination, and arrangement of the parts of a switch as described; (2) the constructing of switches with the contacts tapered and so arranged that by horizontal movement or rotation of either the central portion or the contact blocks the circuit shall be made or broken.—No. 9917. June 17th, 1889. 6*d*.



INCANDESCENT LAMPS.—*A. A. Goldston, Middlesbrough.*—The object of the invention is to provide incandescent lamps with improved cut-outs adapted to operate automatically when the carbons become destroyed. Each leading wire within the lamp has a contact piece attached to it, and between the two contact pieces is arranged a cone or wedge of insulating material. To the lower part of the insulating material is secured a metal piece which is adapted to complete the circuit between the contact pieces on the leading wires at the required moment. To the upper part of the insulating material, and to the upper inner part of the lamp is secured a helical spring, which thus has a tendency to lift the insulating cone or wedge, and complete the circuit between the contact pieces or the leading wires. The upward motion, however, of the cone or wedge is prevented by its shape, which tends to force apart the contact pieces, and so the ends of the carbon filament, by the motion upwards. The carbon filament is at first of sufficient strength to resist the action of the spring upon the cone, but as it gets weaker from wear its ends are forced apart, and the contact is made. Claims: (1) In an electric incandescent lamp having a light-emitting conductor of the kind hereinbefore described, the employment, in combination with contacts fixed to or formed integral with the leading-in wires within the bulb, of an independent movable short-circuiting or contact piece attached to or formed integral with a piece for exerting a wedge-like action upon the leading-in wires, but capable of movement so long as the light-emitting conductor is intact, but which piece when the conductor is ruptured is free to move under the action of a spring or weight; (2) in an electric incandescent lamp of the kind provided with cut-out mechanism the employment of steadying arms; (3) the manufacture of light-emitting conductors for electric incandescent lamps as described; (4) in an incandescent lamp provided with cut-out mechanism of the kind described, a guide stem upon which the movable contact piece slides; (5) the manufacture and use of electric incandescent lamps constructed as illustrated in the specification.—No. 6544. April 16th, 1889. 8*d*.

CHEMISTRY.

OBTAINING ALUMINIUM.—*G. Bamberg, London.*—In the production of aluminium from its chloride, or from the double chloride of aluminium and sodium, by means of zinc, it has been proposed to bring these bodies together, in the solid or liquid form, under heating, whereby zinc chloride is formed and aluminium is set free. Difficulties arise, however, in this process which have prevented its practical adoption. According to the present invention these difficulties are avoided by volatilising the zinc in the first instance, and then bringing the zinc vapour, together with the vapour of aluminium chloride, or of the double chloride of aluminium and sodium, at the temperature of a white heat under the exclusion of air. The chemical affinity of the zinc for the chlorine of the chlorides is thereby increased, and both the zinc and the chloride or chlorides are brought into intimate contact in the finest possible state of subdivision, so that a most effective reaction of the particles is established, resulting in the ready production of chloride of zinc and the setting free of the aluminium, which condenses to metallic form. In practically carrying out the invention, a suitable retort is nearly filled with zinc, previously melted, and of as pure a quality as practicable, and another retort is partially filled with the chloride of aluminium or the double chloride, or materials such as would produce the vapours of the chloride upon being raised above clear red heat (1,040° C.). These retorts are connected with a third retort or suitable mixing chamber by pipes or channels, preferably covered with a suitable non-conducting material, so that no sublimation of the chloride or condensation of the zinc should take place in them. The mixing chamber is maintained, under exclusion of air, as nearly as possible at a white heat at the part where the pipes from the retorts enter, while the further end should be at a lower temperature, so as to allow the particles of aluminium and zinc to run together therein in the form of a liquid to be drawn off to cool. The zinc chloride will escape at the furthest least-heated end as a vapour, and it can then be condensed to a liquid state by means of any of the usual cooling apparatus. The mixed zinc and aluminium is distilled, the zinc going off as vapour, which may be injected directly into the above mixing chamber again, to economise fuel, or it can be cooled down to solid form; the less volatile aluminium remaining behind in fluid metallic form is run off and solidified. One claim is made.—No. 7667. May 8th, 1889. 4*d*.

MAGNESIC CHLORIDE AND OXYCHLORIDES.—*T. M. Lyte, London.*—One of the chief impediments to the manufacture of chlorine from magnesic oxychloride is the necessity of drying the oxychloride as usually made and the consequent loss of chlorine as hydrochloric acid. When the magnesic oxychloride is produced in the anhydrous condition the loss is naturally avoided. The inventor produces anhydrous magnesic oxychloride in this state by one of the following methods. By the second method he also obtains anhydrous magnesic chloride. First method: Mixing pure anhydrous magnesic chloride in a fused state with dry magnesia and subjecting to heat. The magnesia, which is powdered and has been strongly burnt, is wetted and fashioned into balls. These balls when left for a short time set into coherent masses, and when heated become anhydrous, retaining the coherence but being porous and absorbent. Second method: Adding to anhydrous ammonic-magnesic double chloride sufficient magnesia to convert the ammonic chloride contained into magnesic chloride (and if oxychloride is produced, enough magnesia in excess to form the oxychloride desired) and expelling the ammonia by heat. The dry double ammonic-magnesic chloride is powdered and mixed with, say, about three-fifths of its weight of dry magnesia, also in powder, and heated to about the fusing point of anhydrous magnesic chloride when the ammonia is expelled. The heat must be applied gradually or the ammonic chloride will volatilise unchanged. Two claims are made.—No. 6172. April 10th, 1889. 6*d*.

TREATING METALLIC ORES.—*S. Alley, Polmadie, Renfrew.*—In treating metallic ores with chemicals, the apparatus usually employed suffers very much from corrosion due to the chemicals; the object of the inventors is to prevent this action and to make certain structural improvements in the appliance. A vertical section of the improved appliance is illustrated. The vessels are coated inside with vulcanised rubber, the vessels being made of iron or steel. The mixing or agitating vessel A is of cylindrical form. It is made with an opening B at one end for introducing and discharging the materials. The vessel is mounted upon hollow trunnions D, the passage C in one trunnion being for the introduction of steam to blow out the air and form a partial vacuum in the vessel, and the passage E for admitting water or a solution. The vessel is closed internally by a valve F pressed downwards by a spiral spring G. In order that the vessel A may be charged and emptied quickly a hopper H is

Industries.

fixed above and a receiving vessel I below it. The receiving vessel is built up of iron plates lined with india-rubber like the agitating vessel. It has a flexible rubber cover J with a mouthpiece K, which is raised to cover the mouth of the vessel A when discharging, to prevent the escape of gases. The mouthpiece K is raised by a hand-wheel L and its connections M N. The act of raising K opens the valve F. The receiving vessel I serves to filter the charge as it leaves the vessel A. Claims: (1) The improved combination of apparatus for treating metallic ores or compounds with chemicals constructed and arranged substantially as hereinbefore described and as shown in the accompanying drawings; (2) a mixing or agitating vessel for treating metallic ores or compounds with chemicals, made of a cylindrical or other convenient form, with an opening at one end, and with the parts near the opening inclined, the said vessel being arranged to rotate about an axis at right angles or inclined to the axis of the vessel, substantially as hereinbefore described; (3) constructing vessels to be used for treating metallic ores or compounds with chemicals, of iron, or steel, or other suitable matter, coated with rubber, substantially as hereinbefore described.—No. 9592. June 11th, 1889. 8*d*.

MISCELLANEOUS.

FILTRATION OF WATER, &C.—*G. W. Hacksley, Sheffield.*—The first part of the invention refers to the method of precipitating the impurities, and the second part to the manner of cleansing the filters. The chemicals for precipitating the impurities are admitted to the water as it passes through the suction pipe of the pumps which are employed to force the water through the filters. The chemicals are thus thoroughly mixed and diffused through the water, and the precipitate will be caught and kept back by the filters. This improved way of dealing with the water is more expeditious than the use of settling tanks. The filters are arranged in series conveniently placed and connected with inlet and outlet pipes. By the arrangement of the connecting pipes and stop cocks, the water, as it is filtered in one or more filters, may be directed to flow in a contrary direction through other filters, and so remove through a sludge pipe the impurities collected in them. By using filtered water for this purpose the filters are not fouled upon their clean sides. Instead of using filtered water, steam may be employed, or steam and water. If some of the encrusted deposit is exceptionally difficult to remove, steam is applied until the crust is thoroughly heated, and the filtering medium charged with steam. The steam is then blown off. This process, if repeated once or twice, will break up the deposit and cause it to crumble to pieces and pass off through the sludge pipe. Five claims are made.—No. 9512. June 8th, 1889. 8*d*.

Copies of the British specifications may be obtained on application to H. READER LACK, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at* ½*d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

ON THE CRITICAL POINTS OF IRON AND STEEL.*

(*Concluded from page* 484.)

INFLUENCE OF FOREIGN ELEMENTS.—In the first place, I must express my thanks to the metallurgists who have kindly procured samples for me, notably to Professor Roberts-Austen and to Mr. Hadfield in England, and to Messrs. Jordan, Brustlein, and Ledeboer in France. Thanks to their help, I have been able to study, more or less completely, the influence of the following elements:—Boron, nickel, manganese, copper, chromium, tungsten, silicon, arsenic, phosphorus, and sulphur.

Boron.—A single sample was examined, prepared by Professor Roberts-Austen, who obtained it by casting iron and crystallised boron together *in vacuo*. The curves of cooling, each of which is the mean of two concordant tests, are plotted in Fig. 6. The bulges in the curve are not very distinct on account of the extreme smallness of the sample, which did not weigh more than four grammes. Two liberations of heat were noted:—a_{r3}/m, of which the maximum is produced between 815° C and 805° C.; $a_{r2}+(m-1)a_{r3}/m$, of which the maximum is produced between 735° C. and 725° C. The two liberations of heat are fairly equal, notwithstanding that in the iron a_{r3} is three to four times stronger than a_{r2}. It follows that the boron has lowered a_{r3} for a portion from 40° C. to 50° C., and for the rest from 120° C. to 130° C. up to a_{r2}. This action is analogous to that of carbon. Moreover, the sample contained no carbon, or merely a negligible proportion, as the curve has no distinct point a_{r1}. The liberation of heat observable between 980° C. and 940° C. during the progress of cooling down from 1,200° C. represents the solidification of a small quantity of borate of iron, formed by the surface oxidation of the metal.

Nickel.—A single sample was examined, containing—

Carbon	0·337
Silicon	0·047
Sulphur	0·022
Phosphorus	0·223
Manganese	trace
Nickel	5·970

It was obtained by melting together in a graphite crucible lined with magnesia—

Iron (rivets)	80 grammes.
Spiegeleisen (20 per cent. Mn.)	10 ,,
Nickel (in cubes)	4 ,,

The lid of the crucible having melted, the atmosphere of fusion was highly oxidising. All the manganese disappeared, and the metal was very red-short. The test was made with two rods, 5 by 5 by 25 millimetres, cut from the ingot. The cooling (Fig. 6) indicates a single station, $a_{r(3\text{-}2\text{-}1)}$ at 650° C., accompanied by a slackening commencing at 675° C. and ending at about 590° C. In a steel containing the same amount of carbon, the points a_{r3} and a_{r2} would be united into a single slackening $a_{r(3\text{-}2)}$ altogether independent of a_{r1}. Thus, the nickel has considerably lowered the changing-point of the iron, and the change of the carbon has similarly been lowered. The recent researches of Hopkinson in England, and of H. Le Chatelier in France, have shown that in steel containing 25 per cent. of nickel, the critical point is lowered below 0° C. during the cooling, whilst the inverse point during the heating remains near 600° C. These facts are exceedingly curious. Nickel being a polymorphous element like iron, the study of the alloys formed by these two metals will be particularly interesting to pursue.

Manganese.—I have examined the products shown in Table IV., page 506. No. 3 is the same as that already utilised in the carbon series. Each sample of steel was submitted to two successive coolings from 1,100° C. The samples of ferro-manganese were not cooled from a higher temperature than 900° C. They present, it is true, between that temperature and their melting point a certain number of special perturbations which are connected with the liquation of different constituents, and which do not bear upon the facts studied in this paper. The results are given in Table V., page 506. In proportion to the increase in the percentage of manganese, the temperature of recalescence is lowered, and that of the allotropic change of the iron is affected in the same way. Ferro-manganese exhibits nothing more than doubtful traces of arrestation. Thus, the more manganese in the metal, the longer is the iron maintained in the β-condition, and the carbon in the condition of hardening carbon. This effect is very similar to that produced by a more rapid cooling on a non-manganiferous steel containing the same proportion of carbon. In fact, the presence of manganese is equivalent to a more or less complete hardening, and this conclusion is in accord with the known properties of manganese steel. It is known that manganese lessens the malleability, increases the tensile strength, the tendency towards oxidation, the electrical resistance, and the ratio of the residual magnetism to the total magnetism. These properties, however, are due to β-iron, the proportion of which in the cooled steel increases with the percentage of manganese, and not to the manganese itself. Hadfield's highly manganiferous steels, according to the researches of Barrett and Hopkinson, behave like ferro-manganese—that is to say, they do not exhibit recalescence. In these metals all the iron is in the β-condition, which is the normal and stable form of iron above 860° C. But β-iron above 860° C. is not magnetic, and this should be the case with Hadfield's manganese steels and with ferro-manganese. This being actually the case, there is a very striking experimental confirmation of the theory.

Copper.—Professor Roberts-Austen has obtained for me three samples prepared by Dr. Edwin J. Ball and Mr. Arthur Wingham, which have been described in a paper read before this Institute (see Table VI., page 506). The bars were filed from the small cast ingots, and were not regular in section throughout their length. This was, however, of no consequence. The curves are plotted in Fig. 6, each curve representing the mean of two tests. The results are given in Table VII., page 506. In the metal containing 0·847 per cent. of copper, the three points a_{r1}, a_{r2}, a_{r3}, are quite distinct; but a_{r3}, the normal position of which is at 855° C., has already been lowered 40° C. to 50° C. When the percentage of copper increases, a_{r3}, with the exception of a small residue remaining near the normal position, becomes confounded with a_{r2} at about 720° C. Similarly a_{r1} is also lower. It is evident that copper acts

* Paper read by Monsieur F. Osmond, of Paris, before the Iron and Steel Institute on the 8th inst.

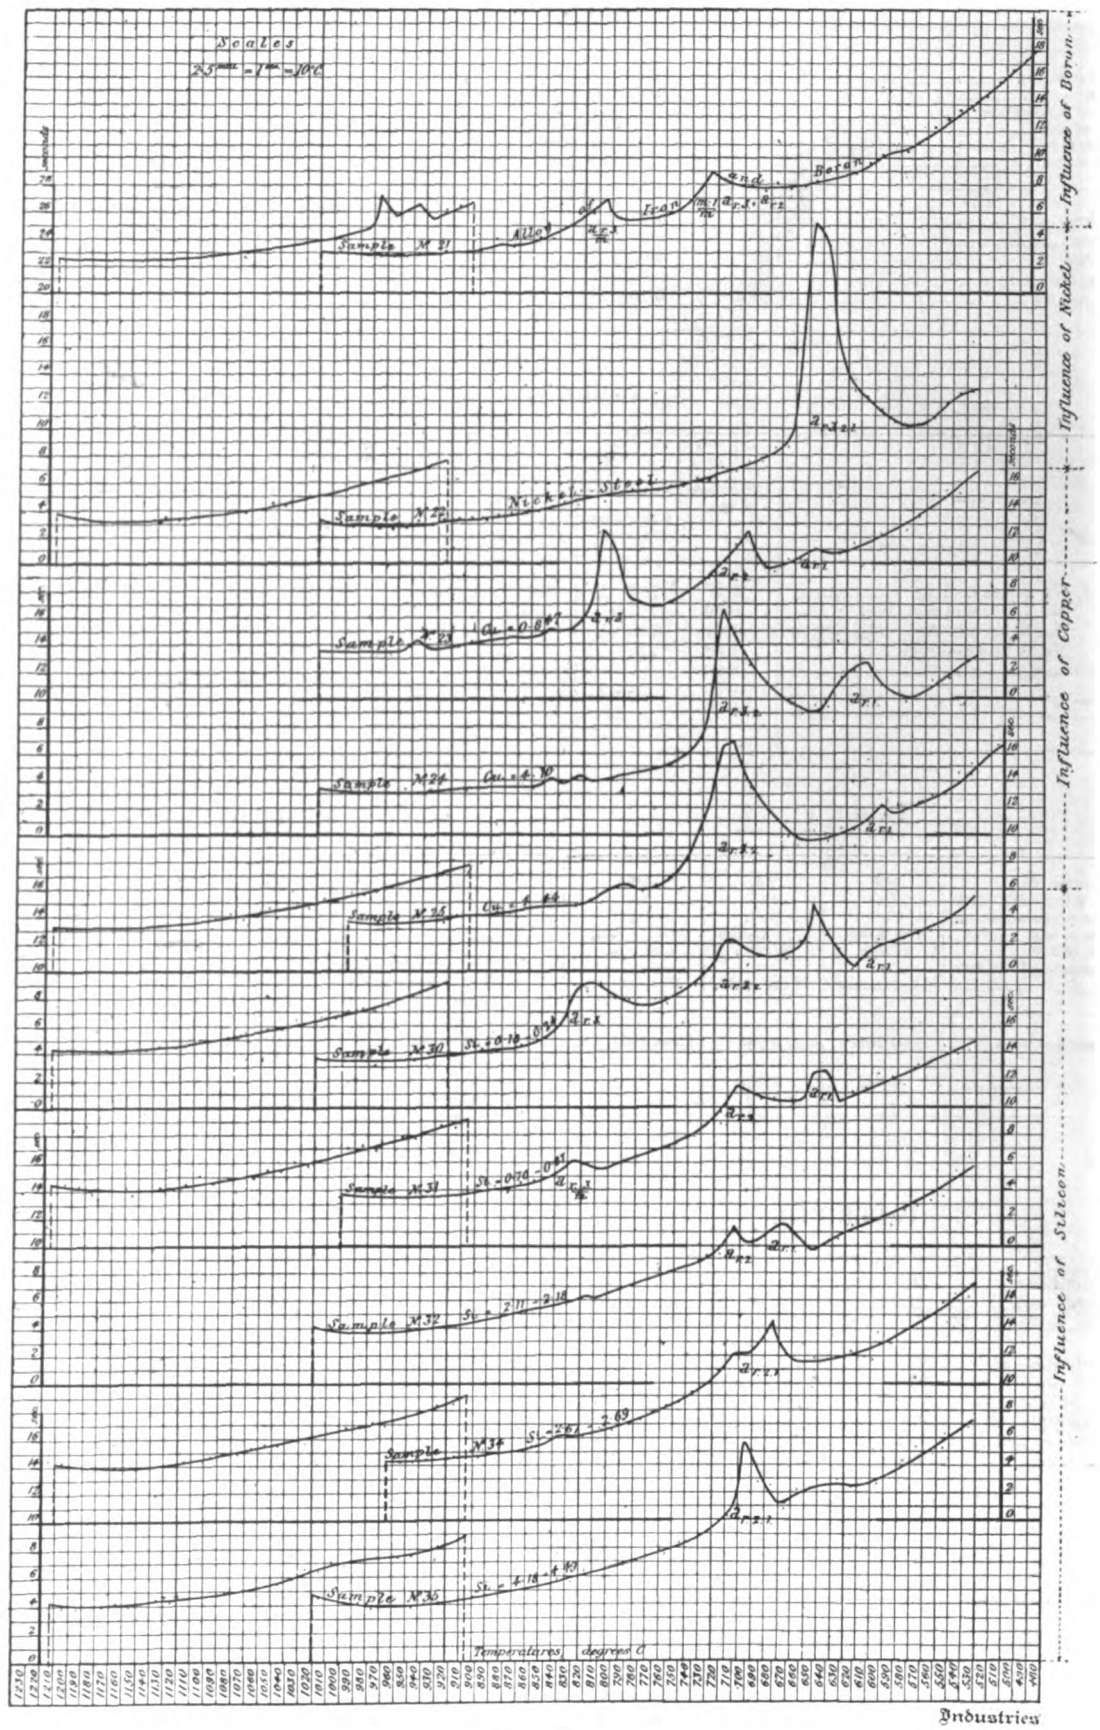

FIG. 6.

in the same manner as the elements previously studied, but in a less energetic manner; 4 per cent. of copper having nearly the same effect on the change of the iron as 0·20 per cent. of carbon.

Chromium.—Three samples were examined. These are numbered 14, 15, and 16, and were obtained from the steelworks of J. Holtzer et Cie., at Unieux. They are in the form of forged square rods, 8 millimetres in side and 60 centimetres in length. Their approximate chemical composition, given by M. Brustlein, is as follows:—

Nos.	Carbon.		Chromium.
14	0·33	...	1·00
15	0·50 to 0·50	...	2 00
16	2·00	...	10·00 to 12 00

In soft chrome steel, the molecular modification of the iron $a_{r(3\text{-}2)}$ begins at about 770° C., exhibits its maximum at about 727° C. (about 720° C. in another test), and is not completely finished at the moment when the change of the carbon commences. The latter gives its maximum at 680° C.

If these results are compared with those given by the sample No. 3 containing no chromium, but with approximately the same percentage of carbon, it is seen that the maximum of $a_{r(3\text{-}2)}$ is slightly higher for chrome steel than for ordinary steel.

Samples 15 and 16, cooled from 1,100° C., present but one perturbation, $a_{r(3\text{-}2\text{-}1)}$, under the form of highly accentuated recalescence.

	No. 15.		No. 16.
The thermometer stops at	676°	...	694°
And continues its rise at	690°	...	716°

By another cooling of No. 16 (the hardest sample) from 800°, the recalescence is changed into a stay at the exceptionally high temperature of 744° C. On the whole, the figures given show that the presence of chromium considerably raises the temperature of a_{r1}. This influence is the opposite to that of manganese; and if manganese is equivalent to hardening, it may be said that the action of chromium on iron has some analogies to that of annealing. If chrome steels reunite in a remarkable degree certain opposite properties, and have the property of being but slightly brittle in proportion to their hardness, we are led to believe that

they owe their hardness to chromium itself, and their consistency to the comparative freedom from β iron. It must be noted that the influence of the initial temperature of cooling on the position of a_{r1} is greater in chrome steels than in carbon steels.

Tungsten.—Four samples, prepared by Mr. F. W. Harbord, have been procured for me by Professor Roberts-Austen. The test-pieces were cut from forged bars, the dimensions being 5 by 5 by 40 millimetres. The chemical composition is as shown in Table VIII. The curves are plotted in Fig. 7, the results being given in Table IX. The points a_{r3}, a_{r2}, and a_{r1} remain distinct throughout. If tungsten steels are compared with steels not containing that element, it is seen that—(1) a_{r2} preserves its normal position and amplitude (for the fall of a_{r3} in Sample 29 is sufficiently accounted for by the percentage of manganese); (2) the same remarks apply to a_{r2}; (3) When the percentage of tungsten is sufficiently high, a_{r1} is considerably lowered. Thus, tungsten does not, up to a proportion of 1·50 per cent., have any appreciable action on the allotropic change of the iron, although it causes the change of the carbon to take place at as low a temperature as 530° C., as I have had an opportunity of proving in another sample of tungsten steel which contained manganese, and was much harder than those of Mr. Harbord. Hitherto we have invariably seen the two changes of the iron and carbon displaced in the same direction under the influence of a foreign element. Tungsten has a hardening action on iron, and is analogous to that of the hardening process, not *per se*, but by the aid of the carbon which it maintains in the form of hardening carbon. These are remarkable properties, quite peculiar to tungsten. It has others; thus, in the hard steel, of which I spoke previously, the fall in a_{r1} is produced only after heating to a sufficiently high temperature. In cooling from 750° C., a_{r1} appears at 670° C., and is separated from $a_{r(3-2)}$; in other words, the action of tungsten in this case becomes analogous to that of chromium, and exactly opposite to that first observed.

Silicon.—Mr. Hadfield has kindly sent me a fine series of samples selected from amongst those employed in his researches, and described in his important paper on alloys of iron and silicon read before this Institute at the meeting in September, 1889. These samples might have been prepared expressly for my researches, for the silicon in them is the only variable. Even had the variations in iron and manganese been regular and of little importance, I should also have obtained good results. All the bars were forged, and measured 6 to 7 millimetres square and 12 centimetres long. Their chemical composition, according to Mr. Hadfield's analyses, was as in Table X. The curves, each of which is the mean of two concordant tests (except that for No. 30), are plotted in Fig. 6, and the results are given in Table XI.

The action of silicon on each of the critical points is easily seen.

1. On a_{r3}. With increasing silicon, a_{r3} tends to rise and to approach the normal position occupied by it in pure iron (855° C.). At the same time the amplitude of a_{r3} rapidly diminishes. It is very much weakened even in the metal (No. 31) with 0·80 per cent. of silicon, and is reduced practically to zero in the richer samples. Moreover, it is not a case of simple displacement; a_{r3} is not found again on the curves to the right, where a_{r2} and a_{r1} preserve their normal intensity, nor to the left, where I attained with the metal No. 34 the temperature of 1,400° C. Silicon prevents the molecular change of the iron, and maintains the iron in the α-condition in the region where, in the absence of silicon, it invariably assumes the β-condition.

2. On a_{r2}. Silicon appears to slightly lower a_{r2} from 725°–710° C. to 710°–700° C., but this effect is imperfectly marked. I may here repeat that a_{r3} appears to represent the end of a_{r2}—that is to say, the allotropic change of the iron, for the molecules immediately dependent on the carbon.

3. On a_{r1}. Silicon gradually raises a_{r1} in a very appreciable manner from 660°–650° C. to 710°–700° C., so that a_{r1} and a_{r2} are caused to coincide in Sample 34. This action is analagous to that of chromium, and the opposite to that of manganese, of nickel, and of copper. These experiments seem to show that, in the metals examined, the silicon is alloyed with the iron, and does not form with it definite compounds. Indeed, during the cooling of the sample No. 33 from 1,320° C., and of No. 34 from 1,400° C., no abrupt and well-defined liberation of heat is observed which might correspond to the solidification of a melted portion, as is the case in pig iron. (*Annales des Mines*, 8th Series, Vol. XIV., pp. 39–59.)

Arsenic.—Three samples were examined. These were prepared by Mr. F. W. Harbord and Mr. A. E. Tucker, and formed part of the series described in a paper read before this Institute. The test-pieces were cut from forged bars, and have the dimensions of 5 by 5 by 40 millimetres. Their chemical composition is shown in Table XIII. The curves, each of which is the mean of two tests, are plotted in Fig. 7, and the results are given in Table XII. Like silicon, arsenic causes a_{r3} to rise towards its normal position, and diminishes its intensity. It is probable that, with a higher percentage of arsenic, a_{r3} also disappears. The action of 0·50 per cent. of arsenic on a_{r2} and on a_{r1} is not appreciable.

Phosphorus.—Two samples were examined. Their chemical composition was as in Table XIV. The curve for the puddled iron is exactly similar to that of electrolytic iron, except that a_{r3} is gradual and not abrupt. The influence of the phosphorus is not yet felt in an appreciable manner, especially as probably an important portion of the phosphorus is in the inactive form of phosphate of iron in intermixed slag. On the other hand, the basic Bessemer metal previous to the after-blow gives, during the cooling from 1,350° C., but a single critical point, and this is very indistinct, at 680° C. (a_{r1}). a_{r3} and even a_{r1} have disappeared—that is to say, the iron preserves the α-condition at high temperatures. Phosphorus, therefore, acts like silicon.

Sulphur.—A red-short basic Bessemer steel, useless in practice, was examined. Its chemical composition was as follows:—

	Per cent.
Carbon	0·48
Silicon	0·08
Sulphur	0·28
Phosphorus	0·16
Manganese	0·51

The dimorphous change of the iron, $a_{r(3-2)}$, presents its maximum between 740° C. and 730° C., and joins recalescence a_{r1}, producing a

Digitized by Google

station at 671°. On comparing these figures given by Sample No. 7, which contains the same proportion of manganese, with 0·32 per cent. of carbon, and only 0·02 per cent., we get:—

	Maximum of $a_{r(2\text{-}3)}$.		a_{r1} (station).
Normal steel	705°–697°	.....	640°
Red-short steel.....	740°–720°	.....	671°

It is thus evident that the presence of sulphur has raised the position of the two critical points some 30°. Thus the influence of sulphur, in so far as it may be determined from a single sample, appears to be similar to that of phosphorus and of silicon.

Professor Roberts-Austen, by studying the effect produced on the mechanical properties of gold by the addition of an equal weight (about 0·20 per cent.) of seventeen foreign elements, has discovered a curious relation between the results obtained and the position occupied by the added metals in the periodic classification ("Philosophical Transactions of the Royal Society," Vol. CLXXIX., 1888, pp. 339–349). Recognising that a similar relation ought to exist in the case of iron, Professor Roberts-Austen, in his British Association lecture at Newcastle, said: "In the case of iron, it is difficult to say what property of the metal will be most affected by the added matter. Possibly the direct connection with the periodic law will be traced by the effect of a given element in retarding or promoting the passage of ordinary iron to an allotropic state, but the future of steel will depend on the care with which we investigate the nature of the influence exerted by various elements on iron, and the thermal treatment to which it may most suitably be subjected." Struck by the originality of these views, and by the importance they might acquire for the iron industry, I revised my early experiments with the object of explaining them, and I also undertook new ones. All the experiments I have described in the last section of this paper, and the general conclusions resulting from them, fully confirm Roberts-Austen's law. The names of the elements, whose action on iron is known, may be arranged in Table XV. in two columns in the order of their atomic volumes. The elements in Column I., whose atomic volumes are less than that of iron (7·2), delay during the cooling, other things being equal, the change of β-iron (hard) into α-iron (soft), and that of hardening carbon into carbide carbon. For these two reasons they tend to increase, with equal rates of cooling, the proportion of β-iron existing in the cooled iron or steel, and, consequently, the hardness of the metal. They are, in fact, equivalent to a more or less energetic hardening. To this list hydrogen might be added, the atomic volume of which is very low, and which renders electrolytic iron hard and brittle, as is well known. Perhaps it would be better to say, with Graham, *hydrogenium*, rather than hydrogen, for hydrogen gas does not appear to have any distinct action. On the other hand, the elements in Column II., the atomic volumes of which are greater than that of iron, tend to raise, during the cooling, the change of the iron towards the normal position that it occupied in pure iron. Moreover, they render the inverse change more or less incomplete during the heating, and hasten during the cooling the combination of the carbon with the iron. Reservations must, however, be made in the case of tungsten. This element exhibits, as we have seen, a certain number of anomalies, and may deviate from the law under certain conditions. Thus they maintain the iron in the α-condition at raised temperatures and *a fortiori* in the cooled metal, and are theoretically a source of softness and malleability, like annealing. If, however, several of them increase the tensile strength and hardness of iron, it is by reason of their personal properties or of that of their compounds, but not by reason of their increasing the proportion of β-iron. In short, they directly play the part of the hardening element which was reserved to β-iron in carbon steels. Thus the foreign elements alloyed with iron act, first, in advancing or retarding, during the cooling, the allotropic change of that metal, in rendering it more or less incomplete, in one direction or the other, according as their atomic volume is greater or less than that of iron. In other words, foreign elements of low atomic volume tend to make iron assume or preserve the particular molecular form in which it has itself its lowest atomic volume, the converse being the case with elements of great atomic volume. These conclusions are in accord with what is known of the influence of foreign elements on the magnetic properties of iron. Indeed, experiments that I have made on this subject (*Génie Civil*, 4th July, 1885), show that, within the limits in which carbon, silicon, sulphur, phosphorus, and manganese may vary in the manufacture of steel rails by the acid and basic Bessemer processes, these elements may be divided into two groups as regards permanent magnetism. In the first group, carbon and manganese increase the permanent magnetism; in the second, silicon, phosphorus, and sulphur have no action on permanent magnetism. Without entering into minuter details, which belong rather to physics than to metallurgy, it is evident that we again find, as regards magnetism, a grouping of the foreign elements into two series. The elements in the first series have a lower atomic volume, and the elements in the second have a higher atomic volume than that of iron.

THE HUDSON TUNNEL AT NEW YORK.

DIRECT communication between New York and Jersey City has long been acknowledged as a pressing necessity. New York, with its population of about 1½ millions, is situated on Manhattan Island, and separated from the mainland by the Hudson River. With one exception, that of the New York Central, which crosses the river at Albany, 143 miles distant, the whole of the railways leading to New York have their termini in Jersey City; in other words, a railway mileage estimated at nearly seven times that of the United Kingdom is barred by the Hudson River from direct access to the commercial centre of the United States. The present ferry service, of course, has all the drawbacks inseparable from this means of communication, such as the cost and delays of transhipment; the difficulties and dangers due to fogs, ice, and storms; and the risks of collision in a crowded navigation. The exact figures representing the traffic between New York City and Jersey City are not known; but it has been estimated that the number of passengers carried per annum exceeds 75,000,000, and the freight carried equals 60,000,000 tons.

It is, therefore, no wonder that the project of building a railway between the two cities has occupied the serious attention of engineers and capitalists. Several years ago an attempt was made to drive a double tunnel through the mud and silt of the river. In 1880 the water unhappily burst into the workings when about 100 yards had been driven, and drowned twenty men. On the resumption of operations a pilot tunnel, or iron tube 6ft. 6in. in diameter, was employed, and it was advanced 30ft. or 40ft. in front of the main tunnel. The silt and water was prevented from crushing the plating and flooding the tunnel by compressed air, which was pumped into the tunnel at a pressure of about 20lb. per square inch. After excavation the silt was mixed with water and ejected by compressed air. When, however, about one-eighth of the distance had been successfully driven, operations were suspended owing to financial difficulties, and the project fell into abeyance.

Some years later efforts were made to resuscitate the enterprise, and the abandoned works were visited in 1888 by Sir Benjamin Baker, K.C.M.G., who was furnished with information by the Company's representative as to the nature of the soil, cost and rate of progress of the executed tunnelling, and other details. In the same year a joint report, based upon this information, was presented by Sir John Fowler, Bart., and Sir Benjamin Baker to the directors of the Company, estimating the time for completion at eighteen months, and the cost of finishing the northern and southern tunnels at £180,000 and £250,000 respectively. According to this plan, the two parallel tunnels will be each 5,600ft. in length under the river and, with their approaches, about three miles in length. The tracks will reach Broadway by easy gradients only 16ft. below its level at the New York end, and will also rise by easy gradients to the street level at Fifteenth Street, at the Jersey City end. Early in the following year an issue of £300,000 six per cent. mortgage bonds, forming the first part of a total authorised issue of £550,000, was made in London for the purpose of carrying out the scheme, and the contract was shortly afterwards let to Messrs. S. Pearson & Son, of Westminster, Mr. Hutton, of New York, being the engineer, and Messrs. Fowler, Baker, and Greathead the consulting engineers.

Before passing to a detailed account of the shield now to be employed in the execution of this important enterprise, we may briefly state in general terms that the

THE HUDSON TUNNEL SHIELD.

CONSTRUCTED BY MESSRS. WILLIAM ARROL & CO., DALMARNOCK IRON WORKS, GLASGOW.

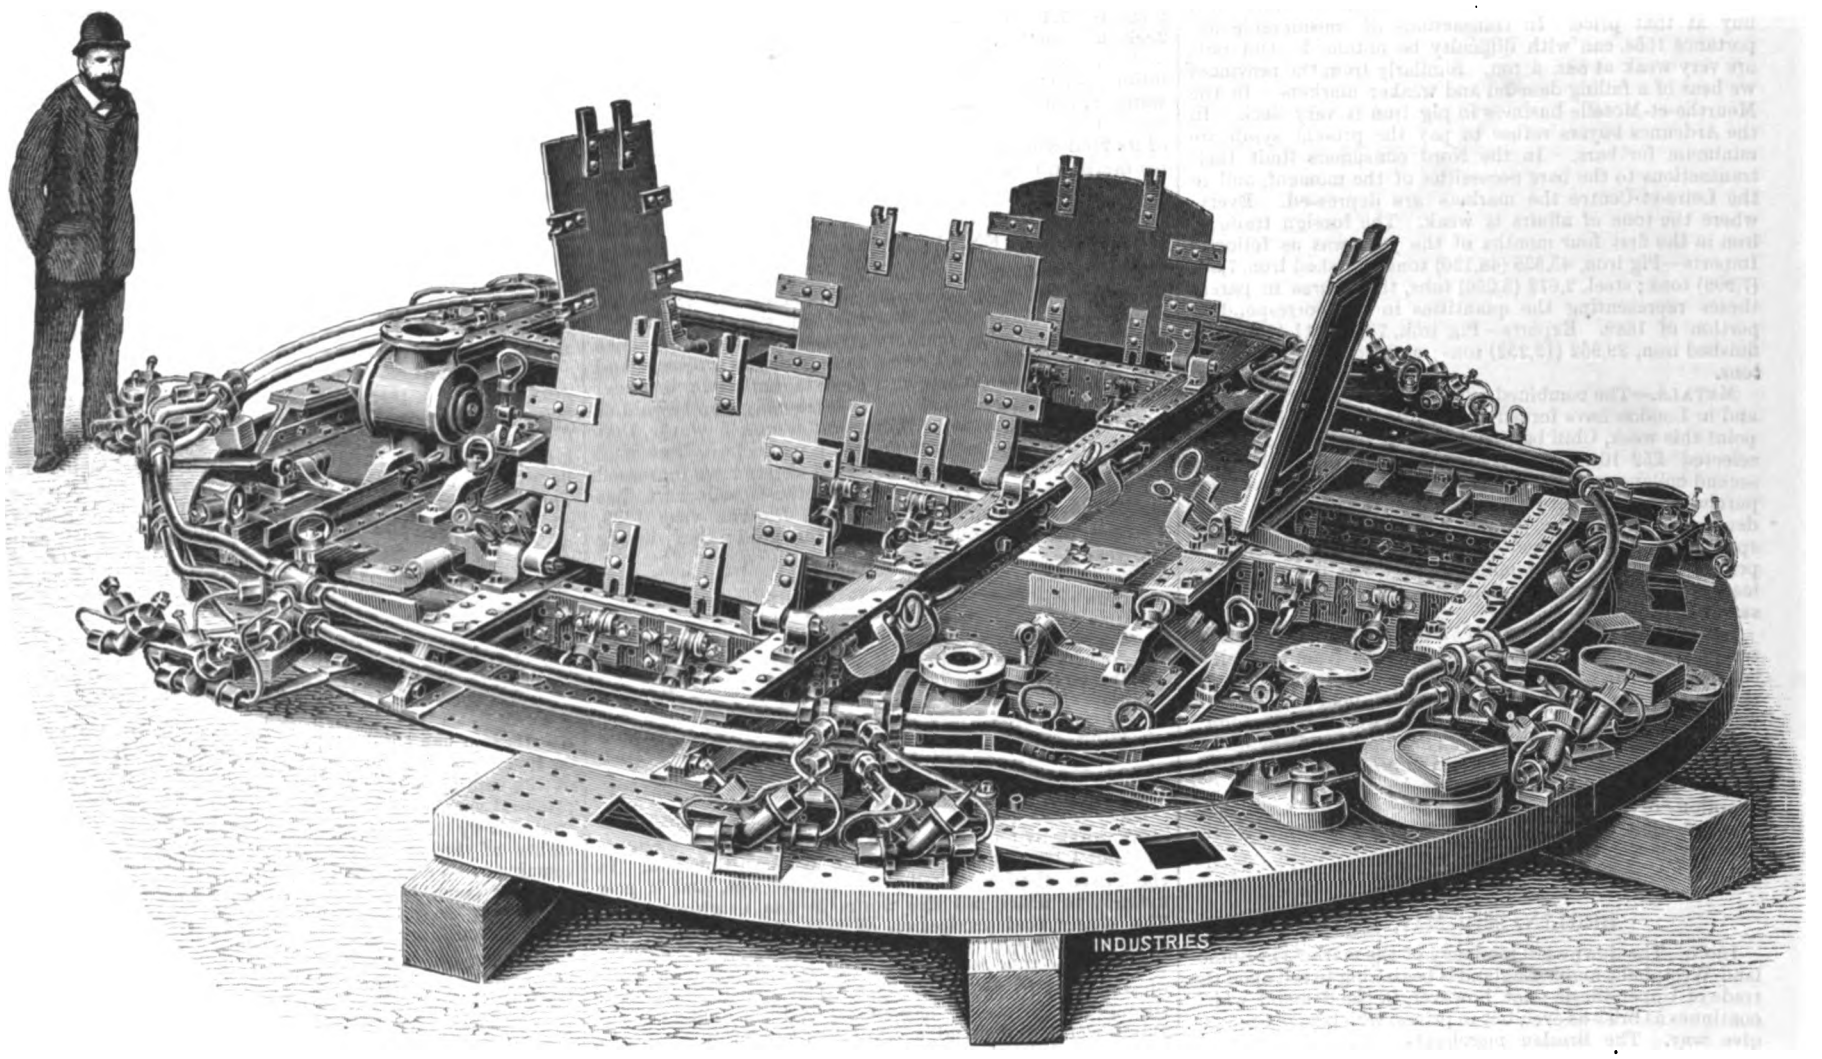

FIG. 3.

shield is supported against external pressure by vertical girders. The face of the shield is formed as a cutting edge, and horizontal shelves extending across the shield are similarly armed to pass through the material met. Behind the cutting edges the shield is closed by a diaphragm of plates completely separating it into two compartments. In this diaphragm doors are placed which can be opened to admit the material being excavated, and the pressure of compressed air in the tunnel prevents the admission of water. When harder and water-tight material is traversed the doors are opened, and the excavators attack the face of the heading. When a sufficient quantity of material has been removed, hydraulic rams attached to the shield advance it by acting against the lining of the tunnel already completed and in position, and a fresh section of lining is at once added. The illustrations which we give in Figs. 1, 2, and 3 herewith, show the shield in several stages of erection in Sir William Arrol's Dalmarnock Works, near Glasgow. We need not add any detailed description of the views, as they are sufficiently self-explanatory.

We will now turn to details of the shields under consideration. The external diameter is 19ft. 11in. by 10ft. 6in. from cutting edge to tail of shield. The outer skin is made up of two thicknesses of $\frac{5}{8}$in. steel plates, with internal covers, and packing pieces between the covers, all of a similar thickness. A division of plates, $\frac{5}{8}$in. in thickness, is placed 5ft. 8in. from the cutting edge, and completely divides the shield into two compartments, being pierced by nine doors, of which hereafter. Two horizontal girders between the doors and the cutting edges divide the shield horizontally, the double $\frac{1}{4}$in. webs of these girders being connected to the door-plates and vertical diaphragms by 6in. by $\frac{3}{4}$in. angles. The two vertical diaphragms, which divide the shield similarly throughout its entire height, are built of 4in. by 4in. by $\frac{1}{2}$in. angles and a $\frac{1}{4}$in. web. The face of the shield is thus divided by these horizontal and vertical girders into nine cells, access to each of which is gained through a door from the after compartment of the shield. The inner skin of the shield is composed of $\frac{1}{2}$in. plating, and extends from the plates forming the division of the shield carrying the doors to within 2ft. 4in. of the cutting edge, and is separated from the outer skin by a distance of 1ft. 5in. Sixteen diaphragms of $\frac{1}{2}$in. plates 3ft. 2in. by 1ft. 5in., with 4in. by 4in. by $\frac{1}{2}$in. angles running completely around on each side, are spaced equidistantly around the shield between the two skins, and arranged to coincide with the attachments of the horizontal and vertical girders already described at their respective junctions with the inner skin. The doors are nine in number, of $\frac{5}{8}$in. plates; seven are square and dished, covering openings ranging from 2ft. 6in. by 2ft. to 2ft. 3in. by 1ft. 9in., the two remaining ones being triangular and about 2ft. square; the clips, hinges, brackets, &c., being stout iron forgings, and calling for no special remark. The doors are faced at the bearing surface with indiarubber $\frac{1}{4}$in. in thickness. The $\frac{5}{8}$in. plates forming the vertical division of the shield are stiffened by six vertical girders 6$\frac{1}{2}$in. in depth, and each made up of four 3in. by 3in. by $\frac{1}{2}$in. angles, with a top flange plate 6$\frac{1}{2}$in. by $\frac{1}{2}$in. and a $\frac{1}{2}$in. web. Sixteen cylinders of cast steel are placed between the two skins equidistantly around the shield. They are 3ft. 4$\frac{1}{4}$in. over all, with external and internal diameters 10$\frac{3}{4}$in. and 8in. respectively. The rams have an internal diameter of 3$\frac{1}{2}$in.

The cylinders and rams were cast by the Steel Company of Scotland at their Newton Works, and prior to despatch were tested to a pressure of 2 tons per square inch, all cocks, tees, valves, &c., being similarly tested to a like pressure. The shields have been made by Messrs. William Arrol & Co., Dalmarnock Iron Works, Baltic Street, Glasgow, to the order of Messrs. S. Pearson & Son, 10, Victoria Street, Westminster. The hydraulic segment erecter, which will follow up the shield in the tunnel, placing the cast-iron lining segments in position as the tunnel advances, has been manufactured by Messrs. Fullerton, Hodgart, & Barclay, Vulcan Foundry and Engine Works, Paisley. A finished view of this apparatus we hope shortly to be enabled to place before our readers. It may be stated in conclusion that Mr. Moir, late of the Forth Bridge, is carrying out the works as Mr. Pearson's agent in New York.

THE NAVIGATION OF THE EUPHRATES.

THE Turkish Government has lately been considering the question of the possibility of navigating the Euphrates in all seasons. The engineers charged with the labour of investigating this point have completed their report, and have expressed the opinion that no very serious obstacle stands in the way of the project. Midhat Pasha, while he was Governor-General of Bagdad, established a service of steamers which were of great advantage to the trade of the province, but which were promptly suppressed as soon as the Governor had changed his residence. The engineers estimate that the only works necessary would be the removal of the remains of old sluices, the dyking of the fords, and the destruction by means of dredges of the moving banks of sand stirred up by the current. The necessary outlay for these improvements would be half a million francs, without counting the cost of the floating material. It is proposed to raise this sum by proportional charges on the revenues of the Imperial property in Aleppo, Mosul, and Bagdad. It is understood to be the intention of the Sultan to establish a regular service by means of a sufficient number of steamers, and to give back to Aleppo part of the trade of Bagdad now drawn away by the Suez Canal. The projected works will be the precursors of the great railway which must ultimately unite the Mediterranean to the Persian Gulf. It will also insure a proper movement to the agricultural products of those provinces, which, at present, in abundant years, are heaped up in warehouses until they spoil for lack of means of transport to other markets. If the project becomes realised, it will be worked from the office of the administration of the Imperial land property in Constantinople.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 27th May, 1890.

IRON.—The firmness in the iron markets, which never had other than artificial causes, is fast giving way. The Paris merchants find themselves unable to maintain the price of bars and joists at 160s. Not even small consumers will buy at that price. In transactions of considerable importance 156s. can with difficulty be obtained. Old rails are very weak at 88s. a ton. Similarly from the provinces we hear of a failing demand and weaker markets. In the Meurthe-et-Moselle business in pig iron is very slack. In the Ardennes buyers refuse to pay the present syndicate minimum for bars. In the Nord consumers limit their transactions to the bare necessities of the moment, and in the Loire-et-Centre the markets are depressed. Everywhere the tone of affairs is weak. The foreign trade in iron in the first four months of the year was as follows: Imports—Pig iron, 43,838 (48,130) tons; finished iron, 7,564 (7,998) tons; steel, 2,672 (3,056) tons, the figures in parentheses representing the quantities in the corresponding portion of 1889. Exports—Pig iron, 70,959 (11,444) tons; finished iron, 29,952 (12,232) tons; and steel, 12,190 (9,312) tons.

METALS.—The combined efforts of speculators in Paris and in London have forced up the prices of copper another point this week, Chili bars being now quoted £55, and best selected £59 10s. But consumers, knowing well that a second collapse must soon come, continue to restrict their purchases to the bare necessities of the moment. The demand for tin on the part of consumers is languid, but speculators have succeeded in giving an upward turn to prices. Lead, after dropping a point, has recovered the loss. Spelter is again higher, but the demand for consumption is light.

THE CAIL ENGINEERING WORKS.—The question of transferring the Cail Engineering Works from the neighbourhood of Paris to Douai has been definitely settled. At the general meeting of the shareholders, held last week, it was unanimously decided to retain the works at Grenelle.

THE LABOUR COUNCIL.—The Special Commission formed to examine and report on the proposed constitution of a Council or Board of Labour has recommended the adoption of the scheme, and expressed its unanimous decision that it should be made a department of the Ministry of Commerce.

BERLIN, 26th May, 1890.

IRON.—The downward tendency of the markets in Rhineland-Westphalia and in England is beginning to tell upon the trade of Upper Silesia; not, however, in the demand, which continues as brisk as ever, but in prices, which have begun to give way. The Breslau merchants have reduced their rates to 197s. 6d. for bars, a price that is below the manufacturers' quotations. Common plates may be bought for 205s. to 220s., and tin sheets from 225s. to 242s. a ton. Clearly the tendency of the market is downward, in spite of the activity at present existing. The contracts of the Donnersmarkhütte with the Upper Silesian Rolled Iron Association for the supply of pig in the next three years are on the bases of from 46 to 50 per cent. of the price of bars. This makes forge pig about 85s. for the price of bars now current, and would leave it at about 54s. 6d. in the case of bars dropping as low as 115s. from the 195s. to 200s. at which they now stand. The tenders for 1,495 tons of steel rails for Breslau gave 160s. a ton at the works as the lowest offer. This tender was made by Krupp, of Essen. The lowest offer from the Upper Silesian works was 166s.

PIG IRON PRODUCTION.—The total production of pig iron in Germany, including Luxemburg, in the month of April amounted to 398,457 tons, against 416,948 tons in March, and 372,742 tons in April of 1889. This makes the total for the first four months of the year 1,551,497 tons, against 1,455,265 tons in 1889, an increase of 6·6 per cent. The consumption of pig in the first quarter of the current year, as represented by the production plus the imports less the exports, amounted to 1,209,767 tons, against 1,061,408 tons in the corresponding quarter of 1889.

METALS.—The metal market continues animated; but the animation is largely due to speculative business. The influences, however, which are being brought to bear are of a nature to force up prices, and accordingly we find the present quotations all round above those of a week ago. Mansfeld refined copper, £62 to £63; English brands from £58 10s. to £62; Banca tin, £103 to £106; Clausthal refined lead, £15 to £15 10s., and W. H. Silesian spelter, £25 to £26 a ton.

THE DISTILLING INDUSTRY.—The official statistics relative to the distilling industry of Germany show a production of pure alcohol in the half year comprised between October 1st and April 30th amounting to 2,479,161 hectolitres. The quantity of spirits, raw and refined, exported in the first quarter of the current year amounted to 204,724 cwt., against 40,266 cwt. in the corresponding portion of 1889.

GLASSMAKERS' ASSOCIATION.—The general meeting of the Association of German Glassmakers will this year be held in Berlin on June 2nd.

NEW QUICKSILVER MINES.—An important discovery of cinnabar deposits has been made at the village of Kurusz, in the district of Dagrestan in Poland. The ore assays 74·7 per cent. of mercury. Preparations are being made to work those deposits at once.

A LARGE PUMPING ENGINE.—A steam engine approaching completion in the Sächsische Maschinenfabrik vormals Rich. Hartmann, Chemnitz, is among the largest that has ever been turned out from these works. The engine, which is constructed on the compound system, is intended for drainage purposes at the Mansfeld copper mines near Eisleben. The high-pressure cylinder measures 1,590 millimetres internal diameter, and the low-pressure cylinder measures 2,480 millimetres; the stroke of the piston is 2,660 millimetres. The diameter of the fly-wheel is 11·4 metres, and its weight 56,000 kilogs. With 11¼ revolutions per minute the engine will raise 16 cubic metres of water 275 metres high, and under ordinary circumstances yields 1,600 indicated horse-power. This engine is the fifth of its kind which has been made by the Sächsische Maschinenfabrik in recent years.

VIENNA, 26th May, 1890.

THE IRON MARKET.—The stagnation noticed in the iron market last week continues, but without shaking the prices. This circumstance shows that the important decreases of prices in the foreign markets are not yet able to influence the home market. This circumstance causes a reserve and a distrust of speculation, and the stagnation in business will become more marked. The same may also be said of the Hungarian market, with the difference, however, that sheets are in good request and ship plates have been sold in large quantities. Prices of tinned sheets have increased by 10fl. per ton. The Alpine Montan-Gesellschaft has issued its report and balance-sheet for the year 1889. The following are the figures of the production during last year:—

	Tons.		Tons.		
Brown coals.....	745,575	...	36,039	increase	over 1888.
Ores	1,051,144	...	184,727	,,	,,
Pig iron	190,742	...	2,253	decrease	,,
Foundry goods..	10,911	...	2,041	increase	,,
Ingots	76,292	...	4,727	,,	,,
Sheets	13,227	...	155	,,	,,
Rails	19,544	...	13	,,	,,
Wires	8,371	...	402	,,	,,
Steel goods	21,828	...	2,974	,,	,,

The company pays a dividend of 5½ per cent.

THE COAL MARKET.—The Bohemian coal market is extraordinarily animated. The traffic on the Elbe amounts to about 1,300 waggons daily from Western Bohemia. In the Pilsen district a strike has broken out, and it now extends to nearly all the works in the neighbourhood. The yearly coal production of this district amounts to 2,000,000 tons from six large esatblishments. A year ago the strike in this district was terminated by an increase of wages by 10 to 15 per cent. The general movement throughout the empire has encouraged the colliers of the Pilsen works to demand a fresh increase of wages and a reduction of the time of working.

DÜSSELDORF, 27th May, 1890.

IRON.—Business in the iron market continues slack. The prospect of lower prices for coal keeps consumers of iron out of the market in expectation of better terms. This expectation is strengthened by the growing importance of the imports of foreign iron. Spiegel pig has receded in price 2s. a ton. For other sorts, the quotations remain unaltered. The latest official list issued is as follows: Ordinary spiegel pig, 100s.; best Rhenish-Westphalian forge, 78s.; Siegen forge, 80s.; foundry No. 1, 82s.; Thomas pig, 68s.; and Bessemer, 82s. a ton. The demand for bar iron continues to shrink both on home and on foreign account. Joists are still freely dealt in, but the demand is scarcely so brisk as it was a week ago. Hoops, on the contrary, are more inquired for. Plates are in fairly good demand for home consumption; but the export trade is languid. This remark applies equally to wire. The Association of German Iron Founders report business brisk, and the near prospect satisfactory, and announce that no reduction in the price of castings will be proposed in the present state of trade.

COAL.—The expected collapse in the coal market has not yet occurred, but there is a distinctly marked downward tendency in prices. That the danger is serious is shown by the fact that a great meeting of mining shareholders in this district is to devise means for preventing any excessive fall in prices. The means adopted will probably be a restriction of the production by dismissing the least efficient hands. It has caused surprise to learn that in the district of Saarbrück, the price of coal at the fiscal mines has for some sorts been raised within the last week 9d. and 1s. a ton. Here the tone of the market is greatly depressed.

LINEN YARNS.—The situation of the market for linen yarns is not altogether satisfactory. The demand has fallen off considerably of late, and prices are maintained with difficulty. Moreover, these prices are not sufficiently remunerative. A slight improvement is noticeable in the trade of the last week. Buyers are operating more largely, but not above the requirements of the moment. The labour agitations have shaken the confidence in the stability of the industrial situation. The general meeting of the Association of German Linen Goods Manufacturers is to be held in Berlin on the 4th of June.

LILLE, 27th May, 1890.

IRON.—The tendency of the iron market is this week unmistakably feeble. For some time past the volume of business has been shrinking, but the manufacturers have firmly maintained their prices. Now, however, their attitude is less resolute, and we hear of important concessions being made to buyers. Coal cannot, it is believed, be long maintained at its present high prices, and with cheaper coal we must have cheaper iron. This is the reasoning of consumers, and a consequence is that not a ton is bought that is not wanted for immediate use. The pig iron market is lifeless.

TEXTILE MANUFACTURES.—Business in linen goods at Armentières continues above the average of the last three years. Buyers operate freely, and the tone of the market is in all respects strong. The demand on export account is moderately brisk. The declared value of the linen and hempen goods exported from France in the first four months of the current year amounted to £147,800, against £114,120 in the corresponding period of 1889. At Roubaix business in woollen goods remains languid. For raw wool the market is dull and somewhat weak. The declared value of the woven woollen goods exported in the first four months of the year amounted to £4,880,200, against £4,772,320 in the corresponding months of 1889.

FLAX AND YARNS.—The market continues active for home-grown flax, and prices have further advanced in a slight degree. Business is moderately brisk in Russian produce, notwithstanding the continued rise in prices due to the higher rates of exchange. Tows are in good demand on home account, but they are not much inquired for for export. The situation remains unchanged for yarns; spinners easily dispose of the whole of their produce. Jute yarns, which are in brisk demand, are again higher. The declared value of the linen yarns exported in the first four months of the current year amounted to £151,320, against £143,080 in 1889.

AMSTERDAM, 26th May, 1890.

TRAMWAYS IN AMSTERDAM.—The Town Council of Amsterdam has rejected, by a large majority, the proposal of several members to acquire the whole tramway system of the capital and to work it on behalf of the town. The proposal was in the form of an amendment to the Bill, introduced by the town authorities, extending the concession rights of the existing tramway company. The Bill still remains to be considered.

WORKMEN'S INSURANCE IN ROTTERDAM.—The Town Council of Rotterdam has just passed an important enactment providing for the compulsory insurance of all workmen whilst employed at public works. It is provided that no contractors' tenders shall be accepted by the town authorities unless the contractors shall have agreed to a proviso giving the town authorities the right to deduct certain sums of money from the contract price for the insurance of the workmen against accidents or death. In the case of an accident causing the death of a workman, the contractor must agree to pay to his nearest relatives a sum of one thousand guilders, unless the contractor can prove that death was due to the man's own negligence; a similar sum is to be deducted from the contract amount also where an accident takes place disabling the workman for life. In all other accidents the town authorities shall have the right to fix a reasonable amount of compensation to the injured artisan. These proposals were not accepted by the Town Council without some sharp opposition; several members objected to them because they could not be generally applied, and others voted against them as tending to demoralise the workman and to make him careless and improvident.

THE ROYAL STEAMBOAT COMPANY.—This undertaking has had a very flourishing time of it during 1889, and the directors will distribute a dividend of 12 per cent. among the shareholders. The company has now a fleet of twenty-three steamers, valued at nearly 2¼ million guilders. Two hundred and forty-four journeys were made in 1889, extending from the Baltic and the North Sea to the Mediterranean and the Levant. Some of these lines were extended last year, and an attempt was made to establish a direct line of steamers with South Africa, but it could not be called successful. In 1889 the company carried 290,860 tons of goods for 2,712,676 guilders. The net profits were 233,086 guilders, after providing for depreciation and reserve. The company had no accidents last year. Several new steamers are building. The rise in the price of coal has affected the company's profits somewhat, and the directors have been compelled to make new contracts in England, where coal is cheaper than in Germany. Latterly experiments have been made to mix the coals with peat, in the proportion of two-thirds coal to one-third peat. The results are stated to have been highly satisfactory.

COPENHAGEN, 24th May, 1890.

INSURANCE OF WORKMEN.—The insurance of labourers against accidents by the employers is becoming a very general thing in Scandinavia. Among others, the Malmö Woollen Manufactory has insured 740 men for an aggregate sum of 1,125,000kr.

THE STATE TELEPHONE IN SWEDEN.—The second large State telephone connection right across Sweden,

Digitized by Google

between Stockholm and Malmö, will be completed during the month of August, and will probably be opened for public use in the following month. It was originally the intention to connect this line with intermediate stations, such as Vexiö, Norrköping, Nyköping, &c, but this has now been altered, so that the first line will be direct between Stockholm and Malmö, and afterwards a secondary line, with intermediate station service, will be installed. The State telephone between Norrköping and Linköping has just been completed, and the State telegraphs are altogether pushing ahead with their telephonic installations with much energy.

NEW LIGHTHOUSE AT THE SCAW.—When the new Houstholm Electric Lighthouse was lighted a few months ago mention was then made of the inefficiency of the Scaw Lighthouse, and the Danish Government has now decided to build a new lighthouse and provide a couple of fog-horn installations in this dangerous neighbourhood. The first lighthouse was built at the Scaw in the year 1561, and the present one dates from 1853. Although this has a comparatively powerful light, a large number of shipwrecks take place, and during the last eleven years over ninety vessels have been stranded within a few kilometres of the lighthouse. The position of the new lighthouse is about 14,000ft. to the W.N.W. of the present Scaw lighthouse, and it will be placed as near the shore as practicable. The machinery for the two new sirens will be placed in the lighthouse, from which pipes lead to the sirens. The cost is calculated at about £7,000, of which £750 is for the lenses, £400 for the tower, £500 for the lantern, and £2,000 for boilers and machinery. One siren will be placed in the immediate vicinity to the north-east, and the other about 1 kilometre from it, in the south-western direction.

THE COPENHAGEN WATER WORKS.—Some extensive works are going on at present in connection with the Copenhagen Water Works. One of the reservoirs is being enlarged. The ground is now ready, but on account of the bricklayers' strike the work on the building cannot commence for the present. The deepening of the reservoir situated outside the town is also being proceeded with. During the summer, Copenhagen receives most of its supply of water from artesian wells in the vicinity of the Sändersö Lake, and it is only when the former cannot supply the necessary quantity that the surface water from the lake itself is used. As this class of water is not well adapted for drinking, it is only used in cases of emergency. During the winter, Copenhagen gets its water from another lake—the Damtuss Lake. From the springs and the lakes the water is led to the large reservoirs, close to the water works; from there it passes through the filters, and is then pumped into the high level reservoir at Söndermarken, from whence it passes through the pipes all over the town. The Söndermarken reservoir has hitherto not only been dug out, but also surrounded by large dams. These will now disappear, and by the deepening of the reservoir the top will be level with the ground. The cover will consist of concrete arches, resting upon brickwork pillars, or, if the bricklayers' strike should make this impracticable, pillars of concrete. On the top of the cover there will be shrubberies, &c., but it is not thought advisable to make this area accessible to the public.

THE SWEDISH-NORWEGIAN RAILWAY COMPANY.—With regard to the Norwegian section of this railway, of which no portion has been completed as yet, it is reported that a new syndicate will apply to the Norwegian Government for an extension or a renewal of the concession for the building of a railway from Ofoten to Luossavoura, or even as far as Gellivara.

MADRID, 26TH MAY, 1890

COAL IN SPAIN.—The total amount of coal imported into Barcelona last year was 371,000 tons. Of this quantity 323,000 tons came in British steamers from Great Britain, 3,000 tons in British sailing vessels from Australia, and the remainder in foreign vessels from Great Britain. The quantity continues to increase yearly, although the native coal from San Juan de Abadesas is largely used in the interior of Catalonia for steam purposes, and in spite of the increasing importation of French coal. There is no doubt that Australian coal would be largely used for gas-making purposes if it were not so costly owing to the high freight that has to be paid on it.

A FORTHCOMING EXHIBITION.—An exhibition of appliances for sprinkling vines with chemicals is to be held in Barcelona this year.

THE LEON COBALT AND COPPER COMPANY.—A new company has been formed in England under special circumstances to work mines in Spain. This venture deserves some attention, as it marks the beginning of a new era in mining in Spain. The Spaniards generally, after getting possession of a new mine, hand it over to foreign capitalists, who form companies of which the working capital is all foreign. The Spanish vendors receive shares as payment. The case of the Leon Cobalt and Copper Company is a new departure. The Spanish holders of these mines, which cover some 350 hectares, offered them for sale in England, and a company was organised in London with a capital of £50,000. The bankers, the Union Bank of Spain and England, offered these shares for sale in Spain, with the unprecedented result that the demands for shares at Madrid and Bilbao alone have been double the required capital. It is not yet known what applications there have been at the branches of Barcelona, Valencia, and Seville, nor in the mother establishment at London. The explanation of this is that the Spanish capitalists, especially those of Bilbao, have shown more confidence in the English management of mining business than in their own, and that they are more willing to put their money with them than in a mining business of a purely Spanish character.

STRIKES IN SPAIN.—The strike in the coal district of Asturias has come to an end without any concession on the part of the owners of the mines, and the workmen have resumed work after an average loss of £1 per head. They could not claim shorter hours, because none of them work more than six or seven, and many less. They could not claim higher wages, because they work on contract, and they can make from 1s. 6d. to 3s. per day, according to their ability and the time they stick to their work. At Bilbao the strike has had a different end. There the contractors, as a rule, supply the workmen with victuals at exorbitant prices, and the profit made by the contractors in many instances depends on the prices of these victuals. In fact, the workmen of the mines were the slaves of the contractors. The effect of the strike has been to do away with these practices. The strike at the Belmez collieries is not yet over.

NEW YORK, 17TH MAY, 1890.

IRON AND STEEL.—The iron trade is in about the same condition. Prices are holding their own, and a fair amount of business is being done. In pig iron there has been a good bit of inquiry, but this has not resulted in much business. Buyers are bidding very low, and sellers are not willing to shade prices. The supply continues large, and as long as present prices can be obtained is likely to continue so. In view of the present cost of production sellers cannot stand much lower rates, so that it is likely that the present state of the market will continue until the market improves in the fall. Prices are $18 to $18·50 per ton for No. 1 foundry for small sales, $17 for No. 2, and $16 for grey forge. Southern iron is about $1 less. In manufactured iron the demand is only fair. The business in bar iron is heavy, but as there is considerable competition, it is not easy to get orders ahead, and prices are pretty low. Actual prices are about 1·85c. to 1·90c. per lb. The plate market is irregular, as most makers are anxious for more work, and low figures must be quoted to obtain desirable orders. The outlook for structural iron is not very good, as the amount of business is less than was expected, and prices are being shaded considerably. There is considerable inquiry for steel rails, especially from the west, but as the competition is very sharp the orders will probably be placed at very low figures. In other forms steel is in little demand. Nominal prices for billets are $31 to $33 50 delivered, but these prices would probably be shaded considerably on orders for immediate delivery.

THE METAL MARKETS.—The copper market is strong, and several large sales have been made at 14¼c. to 14⅜c. per pound. The event of the week has been the sale of 8,000,000lb. of Lake Superior ingot to consumers at probably the lower figure. Casting brands are quieter, but the demand is good, prices ranging from 12⅜c. to 12½c. per pound. The tin market has been active, chiefly on speculation, and prices have varied from 20c. to 20·50c. per pound. A large amount of business is being done in lead at advancing prices. Sales to consumers have increased, and there is considerable speculative dealing. Sales have been made at from 4c. to 4·075c. per pound. Spelter is quiet; prices are variable, and the supply is not very heavy. Antimony is in fair demand, and prices are quite irregular.

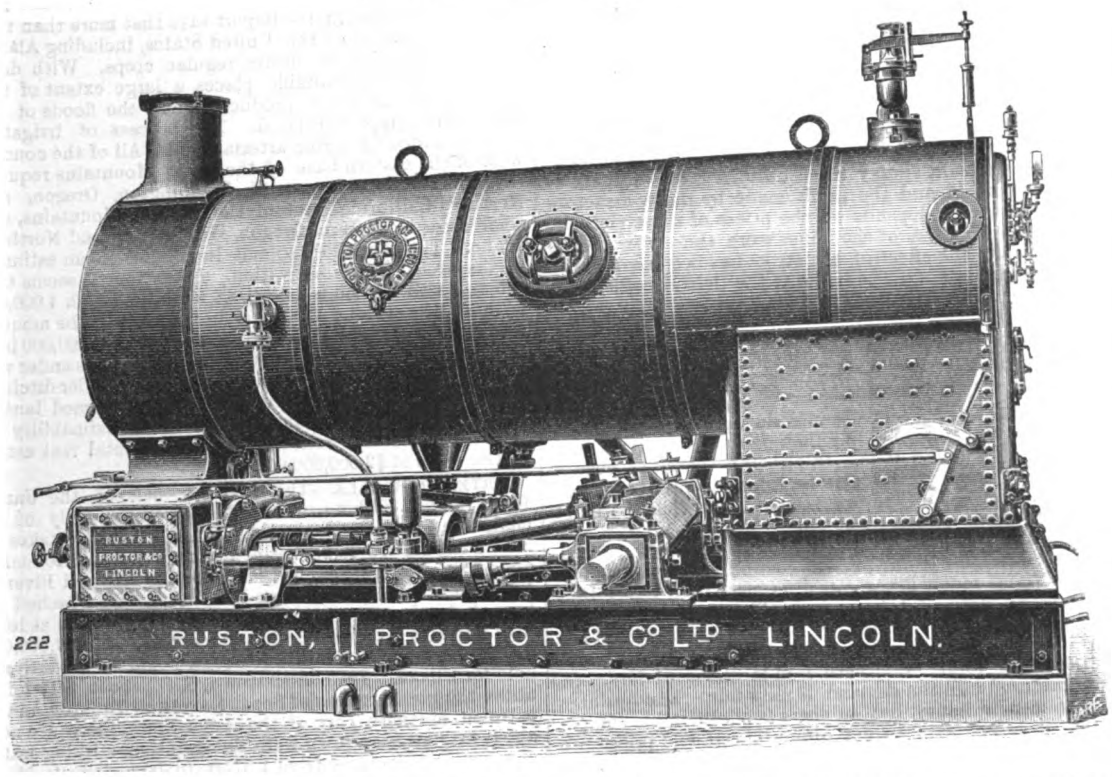
THE COAL TRADE.—The anthracite trade is in a little better condition. Prices are somewhat improved, and the demand has increased. The companies are still standing by their agreement to limit production, and it is probable that if the tonnage can be kept down until the end of June the companies will have the trade in good shape for the rest of the year. Bituminous coal is in an unsettled condition. While prices are nominally kept up to the schedule rates, quite a number of contracts have been taken at a lower figure.

A NEW DRY DOCK.—The new Simpson dry dock has been opened at the New York Navy Yard. The construction was commenced in December, 1887. The dock is built on piling throughout, the floor piling being driven in rows and spaced 3ft. by 4ft. On these heavy Georgia pine timbers are placed lengthwise of the dock, and on these again transverse timbers are placed 4ft. apart. Upon these timbers the working floor of Georgia pine planking is laid, running lengthwise. The keel blocks are supported by four rows of piles capped with heavy timber. The heads of all foundation piles are enclosed in a continuous bed of Portland cement concrete, which also fills all the spaces between the timbers, and rises to the working floor. Open concrete drains lead to the drainage culvert and well. The steps have a rise of 8in. and 10in. tread, and are backed with clay puddle, and are of creosoted Georgia pine. The iron caisson bears against rubber packing attached to the sill and abutments the whole length of the keel and stem, no grooves being used. The dimensions of the dock are:—Full length over coping, 530ft.; full length from inside caisson, 500ft.; width on top amidships, 130ft.; width of floor at entrance, 53ft.; width on top at entrance, 85ft.; depth of gate sill below coping, 30ft. 6in.; depth of gate sill below high water, 25ft. 6in. The pumping machinery consists of two 42in. centrifugal pumps driven by vertical engines, each with 28in. cylinder diameter by 24in. stroke. There are three steel boilers, 13ft. diameter by 11ft. long. The pumps have a capacity of 80,000 gallons per minute, and are capable of emptying the dock in about forty minutes. There are eight flood-gates 22in. in diameter operated by hand wheels on the pump deck of the caisson.

IRRIGATION IN THE UNITED STATES.—The Senate Irrigation Committee in its Report says that more than two-fifths of the area of the United States, including Alaska, requires irrigation to insure regular crops. With dams and reservoirs at suitable places a large extent of this region could be made productive and the floods of the lower Mississippi alleviated. The process of irrigation could be aided by boring artesian wells. All of the country west of the eastern base of the Rocky Mountains requires irrigation except a part of Washington, Oregon, and Northern California, west of the Cascade Mountains, and small areas in Eastern Oregon, Washington, and Northern Idaho. The committee submit in conclusion an estimate of the areas under cultivation. From this it seems that the area under ditch is 13,560,000 acres, of which 4,000,000 is in California and 3,000,000 in Colorado. The amount cultivated by irrigation is 7,763,000, of which 3,300,000 is in California and 1,600,000 is in Colorado. Projects under way and partly completed will bring the acreage under ditch up to 15,000,000 acres. The total value of reclaimed land is nearly $700,000,000. Allowing for the reclaimability of 100,000,000 acres of arid land, we have a total real estate of the value of $2,500,000,000.

ARTESIAN WELLS.—The Artesian belt of the James River Valley, Dakota, is the largest water body of its character known to the world. The James River takes its rise in the Devil's Lake basin, and runs for over 400 miles almost due southward until it enters the Missouri River at Yankton, where the artesian belt has so far reached its largest development. The area thus embraced is at least fifty miles in average width. It contains about 7,000,000 acres, of which certainly 98 per cent. could be made available for tillage. From Jamestown, N.D., about fifty miles above the northern line of South Dakota to Yankton, in the extreme northern part of the same State, there are now about fifty artesian town wells in operation, striking water at a depth that ranges from 1,577ft. in Jamestown to 610ft. and 600ft. at Yankton and Frankfort. There are in all nearly or quite one hundred flowing wells in South Dakota, though all but those named as town wells are usually of small bore, and were sunk for farm purposes only. The remarkable features of this belt of artesian water are its quantity, force, and continuance. The pressure of the principal wells is from 25lb. to the square inch at Highmore to 170 at Yankton, where five wells supply the town with water for domestic uses, town purposes, and as power for manufacturing. The flow of water per minute ranges from 4,000 gallons at Columbia, 3,500 at Aberdeen, 1,500 at Yankton, down to 14 at Highmore. The cost of sinking such wells ranges from $2,700 to $7,300. If the business were systematised, the cost may probably be not over $1,500 each. The altitude ranges from 1,906ft. at Yankton to 1,000ft. above sea level at Grafton.

THE NORTH AND SOUTH AMERICAN RAILWAY.—The Two Americas railway project has been reported upon by a committee of the Pan-American Conference. The committee recommends the appointment of an international commission of engineers, three appointed by each nation, to study the possible routes, determine their true length, and estimate the cost of each. At the present time the city of Mexico is 3,680 miles from New York, *vid* El Paso and the Mexican Central Railroad, and 3,026 miles *vid* Laredo and the Mexican National Railway. A line is in operation 183 miles south of Mexico, and a concession granted for its extension 585 miles further to the borders of Guatemala. A line is also being surveyed for an extension from the border to the city of Guatemala. Lines are projected through Salvador and Honduras, and Nicaragua has a railway system 90 miles long. About 35 miles of an existing Costa Rican may be used in the 210 miles through that State. In the extreme South, the railways of the Argentine Republic are within 120 miles of the Bolivian border, and concessions have been granted for lines to connect with the railway systems of Bolivia and Peru. With these lines built there would be a line 2,190 miles long, from Buenos Ayres to Cuzco, in Peru. Beyond Cuzco, northward to the railways of Costa Rica, a line 2,200 miles long would be required, on which practically nothing has been done. In fact, between Mexico and the northern terminus of the Argentine railway system, a distance of 4,900 miles, there are only 230 miles of railway in operation.



PHILADELPHIA, 16TH MAY, 1890.

FAST RAILWAY RUNNING.—The building of a new bridge over the Schuylkill River has enabled the Philadelphia and Reading and the Baltimore and Ohio Railroads to reorganise their traffic between New York and Washington. The running time of nearly all the trains has been shortened by ten minutes, and a new "flyer" has been added to the service. The northward train leaves Washington at 10 a.m., and Philadelphia (136 miles away) at 12·52, and arrives in New York (226 miles) at 3 p.m. This is the fastest train in the United States.

THE EDINBURGH EXHIBITION.

Compound Undertype Engine Exhibited by Messrs Ruston, Proctor, & Co., Engineers, Lincoln.

THE EDINBURGH EXHIBITION.

PRIME MOVERS.—II.

Messrs. Ruston, Proctor, & Co., Lincoln, have put down an engine which is used for driving the line of shafting in the machinery hall. This engine is a 25 h.p. compound fixed engine, class N, cylinders 10in. and 16in. diameter and 18in. stroke. It is fitted with automatic gear and a high speed governor, and is altogether excellently finished, substantial, and serviceable. The leading exhibit of this firm is, however, an improved compound undertype engine, 16 h.p. nominal (see illustration given above). This engine is also fitted with automatic expansion gear, and is extremely compact. Like others of its type, the engine is placed beneath the boiler. The cylinders are respectively 8in. and 12¾in. in diameter. The stroke is 16in. The cylinders are jacketed, and covered with wood lagging. A patent ejector is employed to drain the steam jackets. The connecting rods are of best scrap iron, and are fitted at both ends with gun-metal bushes. The admission valve of the high-pressure cylinder is automatically regulated by the governor. The variation may be from 1 per cent. to 50 per cent. of the stroke, according to the power required. The gear used is an arrangement of the slot-link gear, a double-ported expansion valve being connected by a radius rod to a rocking slot link, to which motion is given by a separate eccentric. The governor is of the Porter type, and is directly connected to the expansion gear. The feed pump is worked by a separate eccentric; the plunger, valves, and valve seats are of gun-metal, and the delivery pipe is of copper. The feed pump works continuously, the water not required by the boiler being returned to the feed tank. The water heater consists of a branch from the exhaust, connected by a copper tube to the "return" pipe of the pump; the water in the feed tank is by this means raised to nearly boiling point. The crank-shaft is of steel, and is sufficiently long to carry a fly-wheel or pulley at either end. The crank-shaft has three bearings lined with gun-metal. An outside pedestal and sole-plate are also provided. The fly-wheel is 5ft. 8in. diameter, and is turned to carry a belt. The engine runs 135 revolutions per minute. The boiler is of the ordinary type, the plates both of the boiler shell and fire-box being of Siemens-Martin mild steel. The working pressure is 120lb. per square inch. A rapid-action starting valve—admitting steam directly from the boiler to the low-pressure steam chest—is also supplied when the engine is required for hoisting or other purpose for which sudden stopping and starting are necessary.

CLYDE SHIPBUILDING FOR APRIL.

The increasing number of vacant berths in many of the Clyde shipyards, together with the almost total cessation of inquiries for new work, is a matter for regret, as it betokens an approaching period of slackness in this most important industry. Nothing significant was booked during the month, and no very great increase in the way of new business can be expected until the freight markets improve or a falling off in prices for labour and material takes place. The work in hand, however, is vigorously being pushed forward to completion, and the large number of general traders now on the stocks cannot but have a further depressing influence on the existing rates of freights. The past month is credited with an output of twenty-six vessels having a combined tonnage of 42,875 tons, an amount which has rarely been exceeded in the history of Clyde shipbuilding. Considerable interest is attached to two of the vessels contributing to this large tonnage—the "Adder," a fast paddle steamer, constructed by the Fairfield Shipbuilding and Engineering Company, for Messrs. G. & J. Burns, Glasgow, to conduct a daylight service between Scotland and Ireland; and the paddle steamer "Duchess of Hamilton," built by Messrs. William Denny & Bros., Dumbarton, for the service of the Caledonian Steam Packet Company, between Ardrossan and Arran. The "Adder" has a length of 280ft. between the perpendiculars, with a beam of 33ft., and is provided with a set of diagonal compound engines having cylinders of 51½in. and 93in. respectively, with a stroke of 6ft. The guaranteed speed for this vessel is 19 knots. The "Duchess of Hamilton" is 250ft. by 30ft. by 10ft. 6in. moulded depth. She is provided with powerful compound surface-condensing engines, is fitted up in luxurious manner, and has a promenade deck extending her whole length. She represents quite a new departure in Clyde river steamer construction, and when completed will be the fastest and best-appointed craft running on the river.

The following are the particulars of the vessels launched:—

Single Screw Steamers.

"Asphodel," steel, 2,700 tons, and engined with triple-expansion engines by Messrs. A. Stephen & Son, Linthouse, to the order of Mr. J. B. Murray, Glasgow, and intended for general trade.

"Banda," steel, 3,300 tons, built by Messrs. Charles Connell & Co., Scotstown, and fitted with triple-expansion engines by Messrs. David Rowan & Sons, Glasgow, for the Hamburg-Calcutta line of steamers, Hamburg.

"Brand," steel, 2,000 tons, 3,500 tons carrying capacity, built by Messrs. Robert Duncan & Co., Port Glasgow, and supplied with triple-expansion engines by Messrs. Muir & Houston, Glasgow, for Mr. Gunnar Knudsen, Porsgrund, Norway.

"Brazilian," steel, 3,203 tons, built and fitted with triple-expansion engines by Messrs. D. & W. Henderson & Co., Partick, for the South American trade of Messrs. J. & A. Allan, Glasgow.

"Clyde," steel, 5,650 tons, 7,000 i.h.p., built and engined with triple-expansion engines by Messrs. R. Napier & Sons, Govan, for the West Indian, Brazil, and River Plate service of the Royal Mail Steam Packet Company, London.

"Lord Bangor," steel, 3,000 tons, built by Messrs. Russell & Co., Greenock, and fitted with triple-expansion engines by Messrs. Dunsmuir & Jackson, Govan, to the order of Messrs. Dixon & Sons, Belfast.

"Priam," steel, 2,800 tons, 1,500 i.h.p., built and supplied with triple-expansion engines by Messrs. Scott & Co., Greenock, for the China trade of the Ocean Steamship Company, Liverpool.

"Prince," iron, 400 tons, built by Messrs. J. Fullerton & Co., Paisley, and engined by Messrs. Muir & Houston, Glasgow, for the general coasting trade of Messsrs. J. & J. Hay, Glasgow.

"Ping Suly," steel, 3,150 tons, 2,500 i.h.p., built and fitted with triple-expansion engines by Messrs. Barclay, Curle, &c., to the order of the China Shippers' Mutual Steam Navigation Company, London, and intended for their service between London and China.

"Rotokino," steel, 2,000 tons, built by Messrs. William Denny & Brothers, Dumbarton, and fitted with quadruple-expansion engines by Messrs. Denny & Co., Dumbarton, for the Union Steamship Company of New Zealand.

"Sama," steel, 700 tons, 700 i.h.p., built and fitted with triple-expansion engines by Messrs. Hanna, Donald, & Wilson, Paisley, for Mr. J. Christensen, Bergen, and intended for the West Indian fruit trade.

"Wodonga," steel, 2,400 tons, 3,000 i.h.p., built and fitted with triple-expansion engines by Messrs. A. & J. Inglis, Pointhouse, for the Australasian United Steam Navigation Company, for trade in Australian waters.

Twin Screw Steamers.

"Apa," steel, 600 tons, built by Messrs. Robert Duncan & Co., Port Glasgow, and fitted with Rankin's patent disconnecting twin-screw engines by Messrs. Rankin & Blackmore, Greenock, to the order of Paraguayan Development Company, and is intended for service on the River Plate.

"Bute," No. 2, iron, 400 tons, built by Messrs. Scott & Co., Bowling, and fitted with compound surface-condensing engines by Mr. W. Kemp, Govan, to the order of Messrs. Hill & Co., Glasgow.

"Duckenfield," steel, 1,200 tons, 1,200 i.h.p., built and fitted with quadruple-expansion engines by Messrs. Fleming & Ferguson, Paisley, to the order of Messrs. J. & A. Brown, New South Wales, for their colonial trade.

"Hornby," 180 tons, built by Messrs. M'Knight & Co., Ayr, and supplied with compound surface-condensing engines by Messrs. Ross & Duncan, Govan, to the order of the Alexander Towing Company, Liverpool, for towing purposes.

Paddle Steamers.

"Adder," steel, 1,000 tons, built and fitted with compound surface-condensing engines by the Fairfield Shipbuilding Company, Govan, to the order of Messrs. G. & J. Burns, for their mail and passenger service between Scotland and Ireland.

"Duchess of Hamilton," steel, 580 tons, built by Messrs. William Denny & Bros., Dumbarton, and engined with compound surface-condensing engines by Messrs. Denny & Co., Dumbarton, to the order of the Caledonian Steam Packet Company, for their Clyde passenger traffic.

"Marchioness of Breadalbane," steel, 250 tons, built by Messrs. John Reid & Co., Port Glasgow, and fitted with compound tandem engines by Messrs. Rankin & Blackmore, for the passenger traffic of the Caledonian Steam Packet Company.

Yachts.

"Tessa," 6-ton racing yacht, built by Mr. James Adams Gourock, for Mr. F. B. Jamieson.

"White Heather," steel, 636-ton steam yacht, built by Messrs. John Reid & Co., Port Glasgow, for Mr. R. Cecil, Leigh.

Sailing Ships.

"Andromeda," steel, 1,900 tons, built by Messrs. Robert Duncan & Co., Port Glasgow, for Mr. G. F. Smith, St. John, New Brunswick.

"Chicharra," steel, 460 tons, schooner, built by Messrs. Blackwood & Co., Port Glasgow, for the River Plate coasting trade of Messrs. J. & A. Allan, Glasgow.

"Dumbarton Rock," steel, 1,700 tons, built by Messrs. Russell & Co., Port Glasgow, to the order of Messrs. James Cornfoot & Co., Glasgow.

"Garnet Hill," steel, 2,200 tons, built by Messrs. Russell & Co., Port Glasgow, to the order of Messrs. J. R. Dickson & Co., Glasgow.

"Portugo," sister ship to the "Chicharra," and constructed for the same service, by the same builders, for the same owners.

THE "GLOBE" SEPARATOR.

It is highly desirable that the steam which is used for engine purposes should be quite dry and devoid of watery vapour. Many boiler makers provide apparatus, the object of which is to separate the moisture from the steam as it issues from the boiler; but many of them are expensive, and not all of them are certain in their action. Mr. A. G. Brown has recently designed, and Messrs. John Musgrave & Sons, Globe Works, Bolton, are now manufacturing, a new form of separator, which, on account of its simplicity of action and construction, combined with its efficiency, bids fair to have an extensive application. Below will be found illustrations of this apparatus and of its arrangement in the boiler. It consists of a cylindrical vessel, which is placed within the steam space immediately below the steam pipe. It has around its upper portion four orifices, arranged tangentially to its

Exterior View of Separator.

The Separator as Fixed in Boiler.

circumference. The orifices have also a slight downward inclination, so that the several entering currents of steam shall be clear of each other. The steam is thus given a rapid spiral movement, and the whole forms a sort of inverted vortex. Owing to the higher specific gravity of the moisture the latter is thrown against the sides, and from there it trickles downwards. The lower end of the separator is closed by a valve, which oscillates on knife-edged bearings made of hard brass. This valve is very nearly balanced, and a small addition of weight at one end is sufficient to move it. The valve is thus caused to open periodically and the water to fall back into the boiler. The opening of the valve does not allow either steam or water to pass into the separator. The nozzle of the steam pipe is placed just above the water valve, so that the steam has to traverse the whole length of the vessel before finding an exit.

Notices of Meetings.

NEXT WEEK.

Royal Institution.—Friday, June 6th, at 9 p.m. Professor W. Boyd Dawkins, M.A., F.R.S., on "The Search for Coal in the South of England."

Physical Society.—Monday, June 6th. (1) "The Effect of Change of Temperature on the Villari Critical Point of Iron," by Mr. Herbert Tomlinson, F.R.S.; (2) "The Diurnal Variation of the Magnet at Kew," by Messrs. W. G. Robson and S. W. J. Smith.

Society of Chemical Industry (London Section).—Monday, June 2nd, at 8 p.m. Messrs. Cross and Bevan's paper on "Some Considerations on the Chemistry of Hypochlorite Bleaching" will be read and discussed.

Society of Engineers.—Monday, June 2nd, at 7.30 p.m. A paper will be read on "Pick's System of Manufacturing Salt in Vacuo," by Mr. Perry F. Nursey.

Institution of Civil Engineers.—Tuesday, June 3rd, at 8 p.m. Annual general meeting, to receive the report of the council, and to elect the council and officers for the ensuing year.

Chemical Society.—Thursday, June 5th, at 8 p.m. Note on "The Preparation of Pure Crystalline Copper," by Mr. C. C. Duncan.

PRICES CURRENT, 28th May, 1890.

Quotations at per ton, unless otherwise specified.

„	English Ingots	99	0	0	„	.....	

Messrs. Carrick & Brockbank, Manchester, report as follows:—

Copper continues in a strong position, with a tendency to higher rates. The demand for consumption is reported good, and the decrease in stocks this month is expected to be heavier than for some time past. There is still an active speculative inquiry which helps to strengthen values. The London market opened strong on Tuesday, with an active business in Chili bars at £54 2s. 6d. to £54 10s. cash. Manufactured is firm at £66 sheets and £69 bottoms.

Tin quiet, with values unchanged. Although the business done during the week has been small prices have been maintained.

Lead continues inactive, without quotable change in price.

Spelter is a shade easier, but mainly owing to the holidays. The stocks are very low, and it is difficult to get prompt deliveries from smelters.

SHIPBUILDING NOTES.

On the 19th inst. Messrs. Richardson, Duck, & Co. launched, from their yard at South Stockton a steel screw steamer of the following dimensions:—Length over all, 307ft. 4in.; breadth, extreme, 40ft.; depth of hold, 20ft. 2in. The vessel has been built to the order of the Commercial Steamship Company, Limited, of London. She has a half poop aft, with accommodation for captain, officers, and passengers, a raised quarter-deck, and a long bridge from the after engine-room bulkhead to the stem. The engineers are berthed in a deck-house on the quarter-deck, and the crew on the 'tween decks alongside the fore hatch. She has a double bottom all fore and aft on the cellular principle, capable of containing about 560 tons of water ballast. She is fitted with an Emerson Walker's steam windlass, a large donkey boiler, four horizontal steam winches, and every modern improvement for the loading and discharging of cargo. The engines have been built by Messrs. Blair & Co., Limited, of Stockton, and have cylinders 22½in., 37in., and 61in. diameter, by 42in. stroke. As the vessel was leaving the ways she was christened "Darlington."

On the 20th inst. there was launched from the yard of the Tyne Iron Shipbuilding Company, Limited, of Willington Quay-on-Tyne, a steel screw steamer which has been built to the order of Messrs. Jennison, Taylor, & Co., of Sunderland. She is of the following dimensions:—Length, 300ft.; breadth, 41ft.; depth, 22ft. 2in. The engines, which are to be supplied by the Wallsend Slipway and Engineering Company, Limited, are of the triple expansion type, and the cylinders are 23in., 38in., and 61in. diameter, by 42in. stroke. On leaving the ways the vessel was named the "Mendelssohn."

HOME INDUSTRIES.

LONDON, 29th May, 1890.

The Money Market.—The supply of money is largely in excess of the demand just now, and exceedingly low rates are the rule. Even for the Stock Exchange settlement this week lenders have been unable to obtain more than two per cent. for accommodation, for which higher rates are charged as a rule than any other. Discount rates are still low, but with a firmer tendency through fears of further gold withdrawals. No change of importance has occurred in the silver position, but the partisans of that metal are for the moment less sanguine about the promised American legislation. The stock markets have hardly got into full swing after the holidays, as the incidence of the settlement so soon after the Exchange had been closed for a couple of days tended to restrict business all the week. American and Canadian railway securities have been fairly steady without much feature. Among foreigners, Egyptian and Turkish stocks continue in favour, and South American securities have some vogue. Copper shares have risen very considerably, but gold mining shares are quiet. Miscellaneous and industrial securities have shown no characteristic of interest.

Companies.—The following companies have been registered since our last report:—San Francisco Breweries, Ld., with a capital of £1,000,000; Indian Consolidated Gold Mining Co., Ld., with a capital of £275,000; The Planing-Saw Co., Ld, with a capital of £50,000, to acquire certain patent rights; John Brodie & Co., Ld., with a capital of £20,000, to carry on the business of shipbuilders and engineers; Eagle Matting Co., Ld., with a capital of £2,000; Bissol Tin Smelting and Arsenic Co., Ld., with a capital of £50,000; Aberystwith Marine Pier Co., Ld., with a capital of £5,000, to acquire this pier; Neuhaus's Combination Machine Co., Ld., with a capital of £5,000; Emma Co., Ld., with a capital of £125,000, to acquire the New Emma Silver Mining Co., Ld.; Mexican Portland Cement Co., Ld., with a capital of £20,000, to acquire certain patents for the manufacture of cement in Mexico; Congo Exploration, Ld., with a capital of £20,000; Shildon Coal Co., Ld., with a capital of £11,000, to purchase the Shildon Colliery, Durham; Buenos Ayres Western Railway, Ld., with a capital of £6,900,000; Rowland & Marwood's Steamship Co., Ld., with a capital of £275,000; The Berlin National Brewery, Ld., with a capital of £30,000.

Railway Receipts.—The gross receipts of the twenty-three principal railways in the United Kingdom for the week ending the 18th inst. amounted, on 16,159¼ miles, to £1,333,497, and for the corresponding period of 1889, on 16,031 miles, to £1,273,712, an increase of 128¼ miles, or 0·8 per cent., and an increase of £59,785, or 4·7 per cent.

Railway Extension in the West of England.—On the 2nd prox. the Plymouth, Devonport, and South-Western Junction Company's new line from Lidford to Tavistock, Devonport, and Plymouth will be opened for traffic by the South-Western Railway Company, whose trains will run over the line in connection with their through services from London and with the north of England *vid* the Midland Railway and Templecombe. Considerable accelerations in the journey between London and Plymouth are announced, the time occupied being as follows:—To Exeter, 3¾ hours; Devonport, 5¼ hours; and Plymouth, 5 hours and 20 minutes. These fast trains will be extended through the north of Devon to Barnstaple, Bideford, and Ilfracombe. The quickest train at present running between Waterloo and Plymouth performs the journey in a few minutes under six hours; it will be seen, therefore, that the acceleration stated is very considerable.

The Explosive "Fortis."—An addition is about to be made in this country to the list of high explosives suitable for use in practical blasting, the new compound being known as "Fortis." It was invented some three years since, and as soon as it was developed into practical form a factory was erected in Belgium, where it has since been manufactured on a commercial scale, and meets with a steady demand from mine and quarry owners. "Fortis" is made of various strengths suitable for the different requirements of mining, and is a black powder containing some six or seven ingredients, the chief of which are nitrate of potash, sulphur, and tan. In a series of experiments carried out by Mr. C. Napier Hake, in the Mount Sorrel granite quarries, "Fortis" was found to do two-and-a-half times the work of blasting powder. The new explosive is being introduced in this country by the Fortis Powder and Explosives Company, of 17, Coleman Street, London.

Mining in Devon and Cornwall.—The last annual report of the Inspector of Mines for Devon and Cornwall has been laid before Parliament. The total number of persons employed was 13,464, or 275 less than the previous year. The quantity of minerals wrought from the various mines of the two counties was 118,201 tons, of which 12,464 tons consisted of tin ore, 7,688 tons of arsenical pyrites, 7,618 tons of dressed copper ore, 4,758 tons of arsenic, 3,200 tons of iron ore, and 1,200 tons of barytes. Of the rest 81,051 tons consisted of clays, stone, and slate, and there were, in addition, small quantities of zinc ore, ochre, and copper. The number of deaths by accident in 1889 was 23, being one less than 1888, and the number per 1,000 was 1·70. The average for the past seventeen years was 1·63. The inspector thinks that many of the accidents underground are due to the negligence of the miners themselves. There were four prosecutions, followed by the conviction, of mine managers during the year. Tin mining has progressed steadily during the year, in spite of market fluctuations. Amongst the several lodes which have shown a marked improvement, the most important is that being worked at the Carn Brae mine, which has caused the shares to rise 500 per cent. value. Dolcoath mine adit, although sunk to a depth of over 400 fathoms, still continues to make large returns, and the lode at this great depth shows no sign of decreasing in value.

The Mining Exhibition.—The date for the opening of this Exhibition at the Crystal Palace has been changed to the 16th July. It promises to be international in more than name, as it is announced that products of France, Belgium, Germany, Spain, and many other European countries will be represented, in addition to the United States, Canada, Mexico, various South American Republics, Australia, South Africa, Borneo, &c. The Governments of New South Wales, South Australia, and Western Australia have taken space officially.

Her Majesty's Inspectors of Factories.—The Civil Service Commissioners have just issued a new scheme for the examination for inspectorships of factories. Hitherto candidates who could produce a certificate of having been actually employed in a factory or workshop for seven years as employer, manager, foreman, or workman were exempt from a part of the prescribed examination, but the new scheme applies to all candidates, the advantage given to practical men who have been engaged in factories already being that the maximum limit of age is extended from thirty to thirty-eight years. The subjects of examination are—(1) Handwriting; (2) spelling; (3) arithmetic, including vulgar and decimal fractions; (4) English composition; (5) theoretical and practical acquaintance with factories and workshops, including a knowledge of their sanitary requirements; (6) applied mechanics, including elementary mechanical drawing; (7) (*a*) the Factory and Workshop Acts of 1878, 1883, 1888 (Scotland), 1889, and the Truck Acts (1 and 2 Will. IV., c. 37, and 50 and 51 Vict., c. 46), also certain other Acts practically administered by the Inspectors of Factories, such as the Education and Protection of Children Acts; (*b*) an acquaintance with the history of factory legislation in the United Kingdom. Candidates must pass to the satisfaction of the Civil Service Commissioners in all these subjects. When two or more candidates are nominated for one vacancy the competition will be in subjects 5, 6, and 7. The limits of age are twenty-one to thirty, with an extension up to thirty-eight in favour of candidates who have been occupied as master, manager, foreman, or workman in a factory or workshop for at least seven years, and have acquired practical acquaintance with the working of factories and workshops. An official nomination by the Home Secretary is required before examination.

The Automatic Photograph (Foreign and Colonial) Company.—So large an application was made for the shares of the Automatic Photograph Company that the promoters are now putting upon the market another company to carry on automatic photography in foreign countries and in the colonies. It is not necessary to enter here into the question as to the possibility of executing a photograph for a penny in a minute; the only reason we refer to the subject is to point out that in the prospectus of the company the promoters only quote the opinions of the non-technical press.

MANCHESTER, 29th May, 1890.

The Iron Trade.—The market for iron does not improve, and buyers are very scarce. There are a few parcels sold, but prices have to be reduced to effect the sale. Finished iron especially is weak, and orders are very bad to obtain. Many of the old contracts are almost completed, and makers have some difficulty in replacing them. Users cannot be induced to buy ahead.

Greater Manchester.—The Local Government Board has granted a provisional order for the extension of the boundaries of the city of Manchester. An inquiry was held in February last by Commissioners of the Board, who heard the evidence presented and reported to the Board. The effect of the order is to largely increase the area of Manchester, and to include within it certain industrial districts, which are sure to become populous and wealthy in a few years. The present acreage of Manchester is 5,927, its population 378,000, and its rateable value £2,416,330. The additions to be made will raise these figures to 12,788, 480,700, and £2,766,392 respectively. The city corporation is carrying out large water and drainage works in which the surrounding townships will participate, and the burden of which will be jointly carried. Provisional orders have also recently been granted for an important street improvement, and for the clearance of certain congested districts preparatory to the erection of better dwellings.

Sewage Experiments.—The Salford Corporation are at present investigating the subject of sewage purification at their works at Mode Wheel. The lime system has been in operation, but its results have not been altogether satisfactory. Accordingly they are trying the International Sewage Purification Company's system, which is in operation at Acton and other places, and in which salts of iron are used. The system of Mr. William Webster, which is the property of the Electrical Purification Association, is also to be tried later on. The "Amines" system, in which fish brine is the chief agent, is also to be experimented with. The Salford Corporation appear to be making a determined effort to solve a very difficult problem.

The Engineering Trades.—The holiday season has not led to as much cessation of work as usual. Engine builders and millwrights are busy with repairs, in addition to the large volume of new work which they have in hand. The remarkable feature of the trade is the great activity observable in the tool trade. Although there is a general report of fewer orders in other departments, the volume of orders for tools shows no sign of diminution. Railway tools of all sorts are in request, and heavy machinery for treating large forgings are also well ordered. In fact, the activity is remarkable, and there is hardly an exception to this state of things. Textile machinists are also well engaged, and new orders are coming in freely. There are a number of new mills projected, and replacements are also being made in large quantities. Various kinds of humidifiers are being introduced at present, some of them having features of novelty in their mechanism. Mr. Chas. Lancaster, of Manchester, has just perfected an instrument for graphically recording the humidity in a shed.

The Linen and Jute Trades.—The season thus far has on the whole been satisfactory, although in some departments complaints have been freely made as to the unfavourable results of the year's business. Roughs and other goods of a similar make have moved off very slowly, and stocks both here and at Belfast have accumulated, while prices have weakened. Many looms employed in the production of roughs have either been idle or turned on to other fabrics. Of late, quotations have been slightly firmer, and hopes are entertained that matters will improve. There is the more reason for anticipating that such will be the case owing to the fact that cotton roughs have now lost the hold they at one time possessed in the market. This week business has been extremely quiet owing to the holidays, the leading distributors having been closed on Monday, while during the remainder of the week they close at noon. Apart from this circumstance, the general feeling in the linen department is dull, as buyers keep down deliveries as much as possible until after the June stock-taking. The American demand is not as active as was anticipated, and the future course of business with that quarter is not regarded in a hopeful light in consequence of the cablegrams with reference to the discussion on the McKinley Bill in the House of Representatives. The Yorkshire trade is of an average character, and sales of Barnsley linens in the warehouses of this city are fairly maintained. Leeds crashes which are of a superior quality continue to meet with favour.

Projected New Railway.—An agitation has been commenced for the construction of a new line of railway to Windermere. It is proposed that the existing branch of the Midland Railway which connects with the Furness Railway should be extended to Bowness. The object is to obtain easier access to the lake district from Bradford and Leeds, the inhabitants of which can only reach it by a circuitous and slow route. The attention of the directors of the two lines named has been called to the subject.

GLASGOW, 29th May, 1890.

Pig Iron.—As the dealers and brokers were anxious to be relieved from attendance upon a rather listless and wearisome market, the Glasgow pig iron market was closed from the evening of the 21st to the morning of the 27th inst. On the resumption of business on the last-named day a cheerful feeling was manifested. So far as Scotland is concerned there is very little wrong with the trade, but the low price at which Middlesbrough iron is now obtainable threatens to interfere materially in the near future with the present good demand for G.M.B.'s, while special brands are only in moderate request, and are offering daily at drooping prices. A very important change will be brought about in the pig iron trade if a proposal be carried out which the Board of Management of the British Iron Trade Association are said to have in contemplation. This is the controlling of speculation in pig iron warrants by legislation. While, no doubt, serious disturbances are often introduced into the trade by outside "bulling" and "bearing," the difficulties in the way of preventing speculative transactions in pig iron or in anything else would be very considerable. If, however, it were by any means effectively managed, it is probable that in the main it might contribute to the steadying of prices, although there is something in the contention that speculation as often steadies prices as it disturbs them.

Coal Trade.—The fears of a serious drop in prices are so far being falsified, only, however, because the output is being sedulously limited. The result is that prices, both for local consumption and shipping, are steady.

Engineering.—Orders in the engineering world are at the moment rather scarce. The only one of any note is for steel for bridge building, booked by the Steel Company of Scotland. Tube makers have met a falling market by increasing the discount by 5 per cent. There is a general feeling of indifference among buyers, and orders are difficult to secure even at concessions in price. This applies to all the branches of the iron trades.

General Trade.—Though manufacturing industry goes on as usual the exchanges are at a standstill, owing to the English holidays. Shipping business, too, is very dull, owing to there being no London market. Freights are, however, generally steady. The disengaged tonnage is reported as about 24,000 tons register. Two furnaces are about to be blown out—one at Gartsherrie, and one at

Digitized by Google

Eglinton. This will leave 84 furnaces in blast, as compared with 82 twelve months ago.

CONGRESS OF FLOUR MILLERS.—Dr. John Forbes White, of Dundee, has been elected President of the forthcoming Congress of British Flour Millers. The meeting is to be held in Edinburgh about the middle of July.

(From our own Correspondents.)

LIVERPOOL, 28TH MAY, 1890.

ENGINEERING AND SHIPBUILDING.—Although most of the shops and yards on both sides of the river are now exceedingly busy, most of them have had to stop for a few days during Whitsuntide, this being now a recognised holiday time in the district—much more so than formerly. Advantage has been taken of the stoppage to overhaul the machinery and plant, and to effect any necessary repairs, painting, &c. Owing to the beautiful weather the town has been crowded with excursionists from all parts of the country; the traffic across the river by the different ferries, especially to New Brighton, has been enormous, and great credit is due to the Landing Stage officials for the admirable manner in which the traffic was managed, not a single serious accident having been reported. The Welsh and Manx steamers were all crowded, and extra boats to the latter place were put on, all of them being well filled. Considerable interest is centred upon the Welsh competition, but the new boat, "St. Tudno," has proved herself to be a fast boat, and accomplishes the journey to Llandudno in nearly three-quarters of an hour less time than the old boats.

FOREIGN MEAT IMPORTS.—Sixteen steamers arrived in the Mersey during the past week with 6,040 cattle, 1,042 sheep, and 33,401 quarters of beef. Notwithstanding these enormous arrivals, the totals show a decrease of 4,167 quarters of beef, but an increase of 1,015 cattle when compared with the returns for the previous week.

SHEFFIELD, 28TH MAY, 1890.

IRON AND STEEL TRADES.—Most of the works are closed this week. The exceptionally fine weather and the recent good times have given the workmen the means of enjoying a longer holiday than usual. In all the heavy branches of iron and steel work will not be resumed for a week or ten days, as it will be impossible to complete the necessary repairs to the presses, rolls, hammers, and furnaces. The recent fall in prices has caused an influx of railway work to Sheffield, sufficient to find employment to the mills throughout this year. The English Colonies, India, and South America are the chief customers.

THE COAL TRADE.—On Saturday the Duke of Portland turned the first sod of a new colliery shaft at Whitwell, the property of the Shireoaks Colliery Company. This company already raise 350,000 tons of coal per annum from the same coal field.

NORTH STAFFORDSHIRE, 28TH MAY, 1890.

THE IRON TRADE.—Owing to the Whitsuntide holidays the ironworks of the district are at a standstill, and in many cases will not resume operations till next week, advantage being taken of the stoppage to carry out any necessary repairs. There is, on the whole, a somewhat firmer feeling in the trade, and an advance in prices is looked for. Consumers are showing more readiness in giving out their orders and specifications. In the case of pig iron prices have reached a point below the present cost of production, and blast furnaces are being blown out in consequence. The restriction in the output will naturally have a tendency to harden prices.

LEICESTER, 28TH MAY, 1890.

WOOL, SPINNING, AND YARN TRADES.—Owing to the action of the holidays, and to a considerable uncertainty as to fixity of prices, trade has been markedly limited in volume in the wool market since our last report. During the last few days there has been a tendency towards more confidence, but users content themselves with merely supplying their present wants. Trade of a speculative nature is quite absent. Skin wools are not so much in demand, and in these wools there is some stock accumulating. Spinners have their machinery fairly well employed on old contracts, but new business is difficult to obtain, as buyers are very cautious and spinners are trying for rather better rates. As a rule the new business is for immediate wants.

HOSIERY TRADE.—There is a decided improvement in this industry, and orders are being placed freely for heavy woollens, both on home and shipping account. The fancy department is also more active, and the workpeople generally are having fuller employment.

BOOT AND SHOE TRADE.—Up to the end of last week the various factories were engaged to their utmost capacity in filling orders before the holidays. This week but little will be done, but there is every prospect of a resumption of the brisk business on recommencing work. Leather merchants are making a good turnover in supplying consumers' present wants, but buyers will not do any speculative business.

ELECTRIC LIGHTING.—The Corporation have received a draft of the Provisional Order of the Board of Trade in response to their application. It insists on the Corporation providing the light for the whole of the borough. It also compels the Corporation, within two years from the date of the Act confirming it, "laying down suitable mains for distributing the supply" in the area asked for, and also that they do so in any street in the borough within six months of the receipt of a requisition from six or more owners or occupiers. The minimum supply is 20 "units" per quarter. The price is fixed at 8d. per unit, the object being to bring the light within the range of all classes.

SWANSEA, 28TH MAY, 1890.

REOPENING OF IRON MINES.—The Mwyndy Iron Ore Company have just reopened the Llanharry Iron Ore Works, which have been closed during the last fifteen years.

TINPLATES.—The heavy shipments of tinplates, which have reduced stocks by nearly 40,000 boxes, have imparted firmness to this market. Prices show no advance on recent quotations, and common iron cokes can be bought at from 13s. to 13s. 3d., with an advance of from 6d. to 9d. per box for Siemens quality. Nevertheless, the position of makers has materially improved, the competition of the West Coast houses with local manufacturers having brought down the price of steel bars to below £5—a decided reversal of the condition of affairs that obtained only a few weeks ago, when the steelmakers were having it all their own way. It is hence a matter for regret that the attempt to introduce a revised list should now form a new source of trouble. The following are the employers' prices, which the men seem determined to resist:—Rolling, 3s. 5d. per dozen; doubling, 2s. 9d. per dozen; furnacing, 2s. 7d. per dozen; behinding, 1s. 3d. per dozen; shearing, 1s. 1d. per dozen (all 116 sheets to the box); tinning, 3d. per box; washing, 3d. per box; washing by apprentices, list sizes, 2d. per box for the first 5,000 boxes, and 2½d. for the second 5,000 boxes (all 114 sheets to the box); dipping in patent pots, 1½d. per box; greasing, 1d. per box; sorting 6s. 3d. per day, for three sets when working. Boxing payment according to circumstances. XX plates, and all above, to be paid for at the rate of 140lb. per box in mills and tin houses. The disturbance of the standard by establishing 116 sheets to be paid for in mills, as against 114 sheets per box in tin houses, is objected to by the men, who are also against the re-introduction of the apprentice system. The Old Lodge Tinplate Works, Llanelly, are now in active operation. The works possess six mills, and are fitted up with the electric light, having also the very latest improvements in other respects.

BARROW-IN-FURNESS, 28TH MAY, 1890.

HEMATITE PIG IRON.—There is less activity this week in the iron trade, owing to the observance of the holidays as well as to the want of spirit on the part of buyers. The reduction of stocks is a feature which sooner or later will help to stiffen the market, but before that can be done buyers and merchants must be satisfied that the bottom of the decline in prices has been reached. During the week business has been done in hematite warrants at 53s. 3d. cash, but makers, who are still unable to produce pig iron at this figure, are quoting 57s. per ton for mixed numbers of Bessemer net f.o.b. Further restrictions in the make of iron are to be carried into effect shortly.

STEEL.—A better feeling is reported this week in rails and shipbuilding material. Prices for rails are firmer at £5 per ton for heavy sections. The reduction in the selling price of ship plates and angles is evidently resulting in the strengthening of the inquiry for terms of delivery; plates are now at £6 17s. 6d., and angles at £6 7s. 6d. per ton. Tinplate bars, billets, slabs, and blooms are a quiet trade, but there is activity in hoops and wire.

IRON ORE.—There is less doing in hematite iron ore, and the tonnage raised shows a falling off. Prices are steady at 10s. to 12s. at mines.

SHIPBUILDING AND ENGINEERING.—The local yards have suspended operations for the week, but when work is resumed there will be great activity in both departments. The work in the engineering department renders it necessary to work night and day.

MIDDLESBROUGH, 28TH MAY, 1890.

PIG IRON.—It is thought that the bottom price of pig iron has been reached, and that henceforth things will improve. The market opened yesterday with buyers offering 41s. for No. 3 G.M.B., but 41s. 6d. had to be paid, and where brands were specified even more. Warrants were quoted at 40s. 3d., but in the light of an improved prospect holders decline to part with them at that. In hematite East Coast brands have been bought at 55s., which is a good deal lower than the quoted price, and is less than West Coast can be delivered for here.

SHIPMENTS OF PIG IRON.—The shipments have improved of late, and have tended much to strengthen the market. Last week they amounted to 24,845 tons, against 19,975 tons during the similar week last year. As makers have not been holding off so much as they did, the stocks in the public stores have not been drawn upon so much for shipment.

MANUFACTURED IRON AND STEEL.—The finished products are unchanged. The holidays have been fully taken advantage of, as orders are not being pressed for, and manufacturers are in no hurry to complete. Even the low prices seem not to affect the demand. In all probability buyers are waiting to see the price of the raw material settled ere they commit themselves to the finished article, to be sure that they have bought for the best. Iron ship-plates are from £5 10s.; angles, £5 7s. 6d.; bars, £5 17s. 6d. per ton; steel ship-plates from £6 15s.; angles, £6 10s.; heavy rails, £4 17s. 6d. per ton, all 22 per cent. f.o.t. at works.

ADVANCE IN WAGES.—In the face of a falling market, manufacturers, in accordance with the sliding scale arrangement of the Board of Conciliation and Arbitration, have to give an advance of 3d. per ton on puddling and 2½ per cent. on all other forge and mill wages, to take effect from the 2nd of June. The average net selling price per ton of manufactured iron for the two months ending April 30th was £6 16s. 5·73d., as against £6 12s. 2·39d. for the two months preceding.

NEWCASTLE, 28TH MAY, 1890.

THE IRON TRADE.—In spite of the dulness in the finished iron trade, and the substantial reduction in values which has taken place during the past few weeks, the fact is now announced that wages have to be advanced 2½ per cent. This is owing to an arrangement by which wages, instead of being governed by the present state of the market, are regulated by the ascertained average selling price of finished iron during the preceding two months. The ascertainment for May and June will be made in July, when a very different result may be looked for.

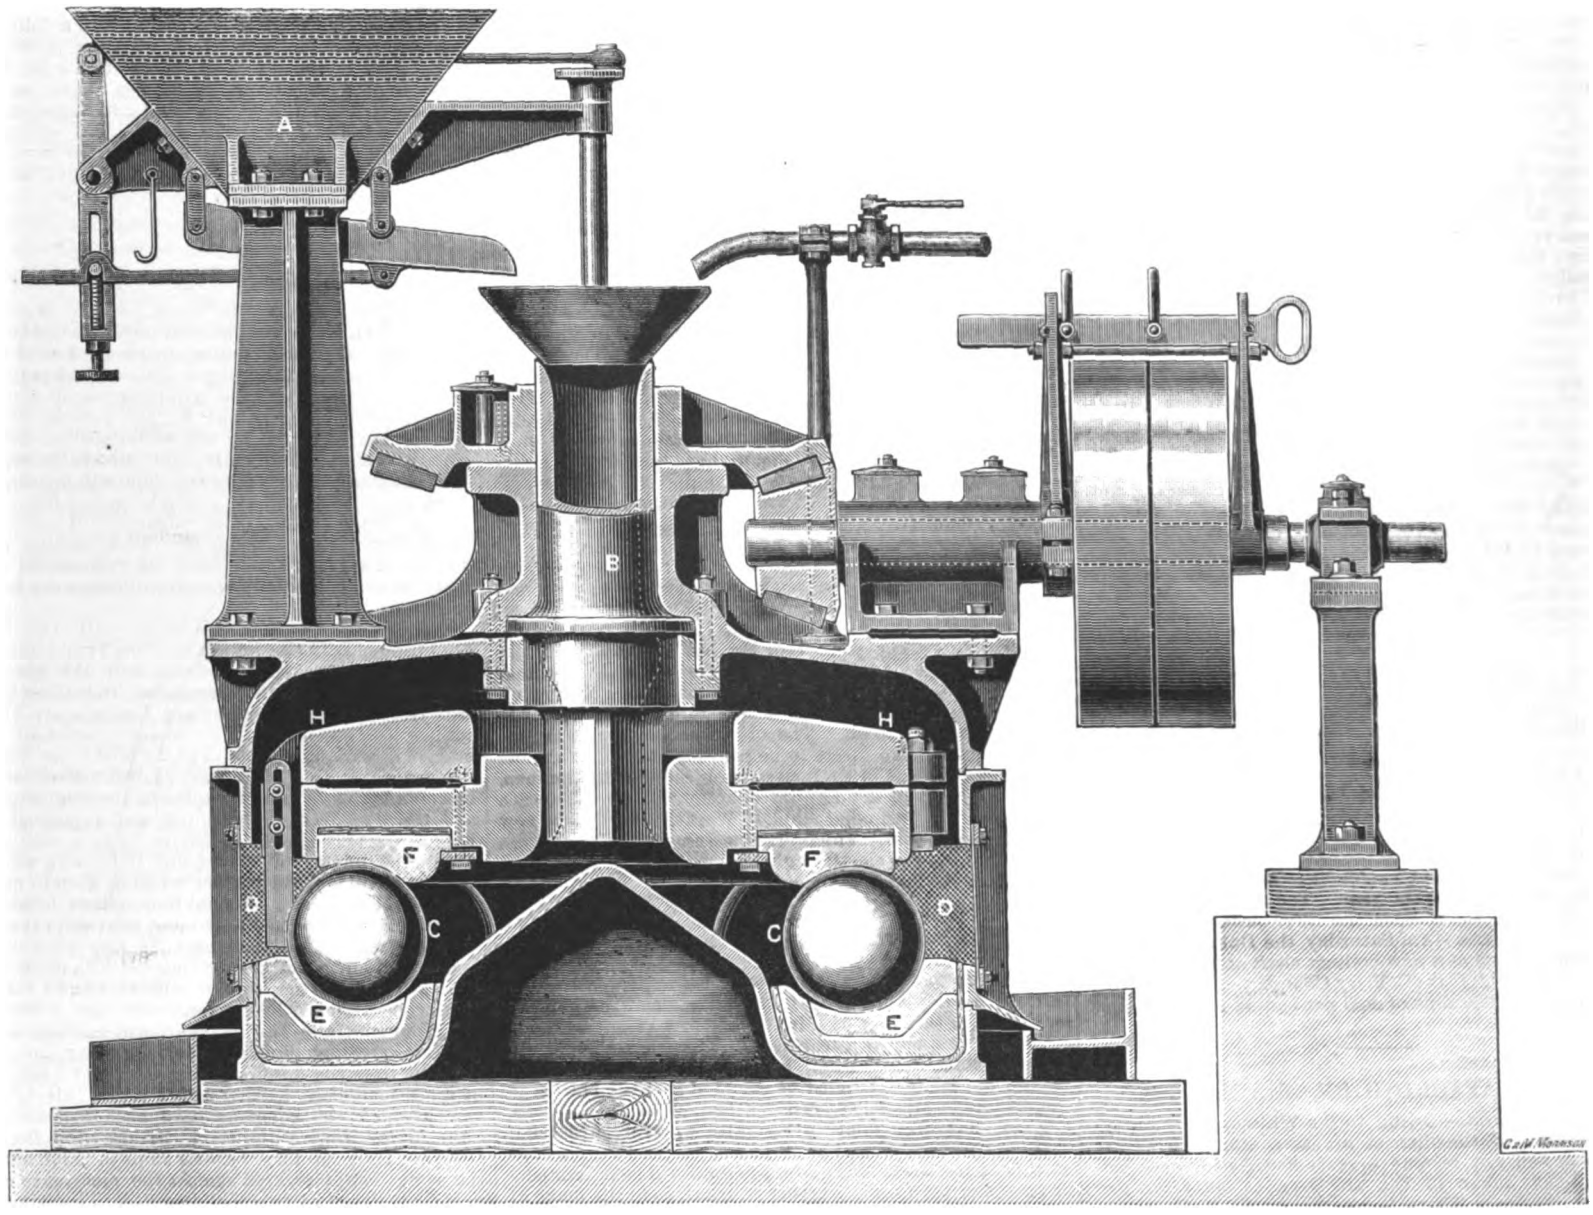
THE COAL TRADE.—The shipments of coal and coke from Tyne Dock during the week ending May 24th amounted to 113,228 tons, being an increase, as compared with the shipments for the corresponding week last year, of 4,093 tons.

THE WHITSUNTIDE HOLIDAYS.—All the industrial establishments in the district are idle during the first half of the present week in accordance with the usual custom at Whitsuntide. It is needless to say that these frequently recurring and unduly prolonged holidays are a cause of serious loss, and it would be to the interest of the community if something were done to abate the evil. Some few weeks ago an understanding was arrived at between representatives of the workmen in the engineering trade and the employers, by which it was stipulated that the holiday periods should in future be kept within certain prescribed limits, and it remains to be seen whether the workmen will on the present occasion keep in mind their part of the compact. Should they adhere honourably to the conditions agreed to by their representatives on the occasion referred to their example may possibly have a good effect on the workmen connected with other branches of industry, and even more beneficent results may follow than were originally looked for.

SHIPBUILDING.—The announcement has been made that the Palmer's Shipbuilding and Iron Company, Limited, have received from the Admiralty an order for two more cruisers of the second class, making five in all of this type of war vessel which the company have been commissioned to build for the home Government. Besides these, the Palmer's Company have two line-of-battle ships to build, and are, on the whole, better secured against the recurrence of slackness than almost any shipbuilding firm in the kingdom.

BELFAST, 28TH MAY, 1890.

SHIPBUILDING AND ENGINEERING.—The dulness in these trades has not yet found its way here. All the shipyards continue busy, and the high wages which have been obtained during the past winter have not in any case been reduced. Two large vessels were launched during the past week; one of them, the "Plassy," will be the eighth ship Messrs. Harland & Wolff have delivered to Liverpool owners this year. Although no new orders are reported in the engineering trade, work still continues fairly good. Boiler makers are also well employed.



THE BELFAST ROPE TRADE.—Although this industry is a comparatively new one in Belfast, it is making very rapid progress. The Belfast Rope Works Company are especially busy, and are at present working overtime three nights in the week, in order to fill the orders they have in hand. It is only a few years since they rebuilt part and enlarged their premises, and now they are obliged to again add to their works. The new buildings will be situated on the opposite side of the Conswater river, and will be connected to the present works by means of three iron bridges.

THE LINEN TRADE.—The proposed American Tariff Bill has caused a good deal of uneasiness in this trade, as there can be no doubt that its effects would be considerably felt here. Sales of yarn have not been large during the past week, and the prices for raw materials have gone up. Flaxes from abroad have advanced in some cases as much as £3 per ton; but as a rule the spinners have large enough stocks to make it unnecessary for them to buy largely at the higher price. A very healthy sign with regard to the North of Ireland linen trade is that many of the large firms are enlarging and improving their works, and in the neighbourhood of Belfast there have been several new main engines and boilers put down lately in connection with this trade. Messrs. William Barbour & Sons are the first in Ireland to adopt the triple-expansion engine for mill driving.

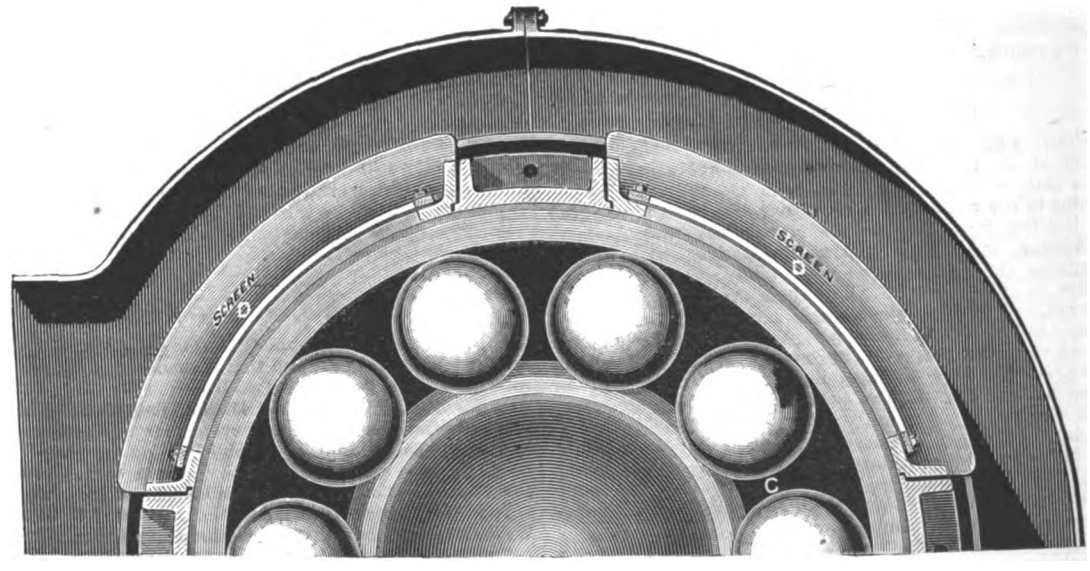
THE LAMBERTON ORE CRUSHING MILL.

CONSTRUCTED BY MESSRS. LAMBERTON & CO., ENGINEERS, COATBRIDGE, NEAR GLASGOW.



VERTICAL SECTION.

THE LAMBERTON ORE CRUSHING MILL.

THE Lamberton ore crushing mill, which we illustrate herewith, is an interesting example of a roller mill applied to the crushing of ores and to the manufacture of cement, phosphates, &c. The adoption of the roller principle marks an important difference between this machine and all attrition mills. In working the mill the material is placed in the hopper A, from which it is automatically fed at any desired rate down the hollow vertical shaft B, and, diverging at the bottom, falls underneath the group of rolling balls C, and so is quickly pulverised. The balls are of hardened steel, ten in number, and are driven round in the cup-shaped renewable track E by means of a heavy rotating disc H, which is also provided with a renewable face F bearing on the top of the balls. The lower end of the hollow vertical shaft has a square end which fits loosely into a square hole in the centre of the rotating disc, and in this way imparts rotary motion to the disc, allowing at the same time perfect freedom for any oscillation which may arise from unequal feeding. In crushing ores by the wet process the water is allowed to enter along with the feed, and the crushed ore is washed out through four screens D in the manner usual in stamp batteries. It is then caught in the circular trough surrounding the mill, and led over the amalgamating plates.

In dry crushing the fan-blades or scrapers attached to the revolving disc H create an induced current of air down the hollow vertical shaft B, which assists in blowing the fine material through the screens D, at the same time serving to draw away all dust from the shaft bearings and keeping the inside of the mill cool. Another arrangement is to allow the mill to deliver freely at one point from which the material is taken to a revolving screen, where the fine stuff is removed and the coarse returned to hopper A for further reduction, the whole being performed automatically. The output in wet crushing is 15 tons per day of twenty-four hours, and in dry crushing 12 tons. Only 6 nominal horse-power is required for driving. The renewable wearing parts—viz., the balls C, track E, and face of disc F—are castings, with no machine work on them whatever, and can therefore be cheaply renewed when worn out. The patentees and makers are Messrs. Lamberton & Co., Coatbridge, Scotland.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to ensure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week.

All accounts are payable to GEO. CAWLEY, *358, Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

To Correspondents.

All communications intended for insertion in this Journal, or relating to Editorial matters, should be addressed to "THE EDITORIAL DEPARTMENT," at our London Offices, 358, Strand, and must, in all cases, be accompanied by the name and address of the writer. No notice will be taken of anonymous letters.

We cannot undertake to return manuscripts or drawings, and must request correspondents to keep copies.

BOUND VOLUMES OF **Industries**,

In half calf, gilt lettered, may be obtained at our London, Manchester, and Glasgow Offices, Price 20s. each.

Industries:

FRIDAY, 30TH MAY, 1890.

MINING IN 1889.

THE summaries of the statistical portion of the Reports of Her Majesty's Inspectors of Mines constitute one of the most instructive publications of the Board of Trade. The volume recently issued, dealing with the mining industries in the year 1889, is specially interesting, because it contains much of the evidence concerning the state of trade, and the immediate prospects of industry in this country which all are anxiously looking for. Moreover, these bare tabular statements convey information on other matters of an important character which men of science and philanthropists will best appreciate. Turning first to that portion of the evidence which relates to the state of industry and trade, we find much that is encouraging, with little or nothing of importance to set off against it. In nearly all directions there has been progress; and if in some there seems at first sight to have been retrogression, a fuller consideration of the subject will reveal relations and tendencies that must be accepted as signs of advance. The number of persons employed in and about the mines classed under the Coal Mines Regulation Act increased from 534,945 in 1888 to 563,735 in 1889, nearly 5½ per cent. This is a mark of prosperity in which the working classes have chiefly shared, for not only has the circumstance given employment to an additional 28,790, but the activity which this fact indicates has enabled all to obtain higher remuneration for their labour. The number of women employed about the mines increased from 3,935 to 4,027. But if we consider them relatively to the total number of persons occupied above ground, we shall find a slight decrease, the proportion being 1 to 23·9 in 1889, against 1 to 23·4 in the previous year. The "efficiency"—that is, the average quantity of mineral wrought per unit of the hands employed—declined a little, as it always does in times of prosperity, when the toiler finds himself able to take some relaxation, the output per head being 336·4 tons, against 341·5 tons. It is instructive to compare this efficiency with that of our Continental neighbours, who, working under less favourable natural conditions, are unable, in spite of a longer working day, to exceed two-thirds of what is accomplished in this country.

The total quantity of minerals wrought in 1889, exclusive of those extracted from the metalliferous mines, which are classed under another Act, increased from 182,660,163 tons in 1888 to 189,633,656 tons last year, or some 4⅓ per cent. This increase was chiefly in coal, the production of ironstone having diminished considerably. The figures which represent the production of coal in this country are of a magnitude to excite astonishment. The output, which amounted to 169,935,219 tons in 1888, rose to 176,916 724 tons last year, an increase of a little more than 4 per cent. The vast importance of our coal mining industry here stands out in striking prominence, showing at a glance whence our industrial greatness is derived. The enormous increase in the cost of coal on the Continent which has taken place within the last twelve months gives additional interest to these latest statistics of production. The increase is the best possible evidence of industrial activity in the manufacturing centres, for the customs returns show that the larger part of the increment has been consumed at home. We learn, too, from the same sources, how great the home consumption of coal is. The exports scarcely amount to twenty-five million tons, and the quantity shipped as bunker coal for ocean steamers is less than ten million tons. More than four-fifths, therefore, of this colossal output is burned in these islands and on board vessels engaged in the coasting trade. Nothing could indicate more clearly the importance of British industry. We cannot, however, contemplate a production of this magnitude, with its constant tendency to increase, without misgivings concerning the duration of our coal supply, and the distant future of the industries which are dependent on it.

From this satisfactory view of trade, we turn to another portion of the summaries which deals with facts relating to the safety of human life in and about the mines. Here, unhappily, the prospect is less pleasing. The tables of accidents are a practical commentary on the working of the Mines Regulation Act, and as such they deserve to be studied with the utmost care and diligence. The results of the year's work, as told by these statistics, are not encouraging. Fatal accidents were numerous in spite of the many precautionary measures rendered obligatory by Act of Parliament, and enforced in their observance by a strict system of Government inspection. There was, it appears, one death by accident for every 530 persons employed in 1889, against one in 602 in the previous year, or 1·887, against 1·660, per 1,000. Expressed in another way, one human life was sacrificed for every 178,227 tons of coal raised in 1889, against one in 205,698 tons in 1888. This absence of progress, where it is so much to be desired, is not to be explained away by means of special circumstances, for none have occurred. The loss of life from fire-damp explosions is, it is true, a fluctuating quantity, and we find in 1889 the number of deaths from this cause 138, against 49 in the previous year. But this very fluctuation is evidence of the persistence of the danger against which one portion of the Mines Regulation Act was directed. There is, moreover a steady persistence in the figures, year after year, in those columns of the tables filled with the records of accidents from other causes, so that we cannot comfort ourselves with the assurance that time will bring appreciable improvement. We can but hope that new means will be discovered and fresh measures devised of greater efficacy and wider scope. The summary which deals with these matters indicates the directions in which future efforts should be turned. There is a belief commonly prevalent among what may be described as the outside public that the principal source of danger to the coal miner is "fire-damp," and that, consequently, the most pressing need is a safer system of lighting the underground workings. Now the total number of deaths from accidents last year was 1,064, of which only 138 are attributed to explosions. Falls of rock are much more destructive of life, the number of deaths last year from that cause being 465. In truth, it may be roughly stated that 50 per cent. of the deaths due to accidents in mines are caused by falls of rock, while the proportion attributable to explosions is below 15 per cent. An explosion, with its numerous victims and its horrible associations, appeals strongly to the imagination, and is heard of all over the country. Individuals are quietly crushed to death beneath a "fall," and no one outside the immediate locality in which it happens ever hears of the occurrence.

Digitized by Google

The number of persons employed in and about the mines classed under the Metalliferous Mines Regulation Act underwent a slight diminution—43,420 in 1889, against 43,472 in 1888. Of these, 1,436 were women, a number greater by 14 than that of the previous year. The number of lives lost by accident in these mines was 64, against 72 in the previous year, or 1 in 678, against 1 in 603; or, differently expressed, 1·474, against 1·656 per 1,000, the average for the ten years from 1874 to 1883 inclusive being 1·645 per 1,000. This is an improvement; but other years, notably 1884 and 1887, have shown better results.

LORD ROSEBERY ON CO-OPERATION.

The annual function of the co-operators at Glasgow was rendered notable by an address from Lord Rosebery as clever and interesting as Lord Rosebery's addresses usually are. The co-operative movement is in the full blaze of its prosperity. It wields a capital of over ten millions of money, turns it over three and a half times a year, and makes a gross profit upon it of something like 30 per cent. This is a business too big to despise, and yet, after all, the co-operative movement, big as it is, hardly seems to affect general business in an appreciable degree. It has, for the most part, wisely kept itself to small things; the Ouseburn experiment was too great a failure for repetition. It needs no uncommon prescience to see that the growth of the co-operative movement on "shop-keeping" lines must go on. Delusive as are the advantages of dividend-making, the idea has obtained too firm a hold upon the working classes to make them readily forego it. No matter though pretensions to social progress by means of a discount on purchases may be exposed ever so plainly, the growth of the co-operative movement through this very principle is one of the most remarkable instances of the facility with which people are victimised by illusory advantages. Yet the fact that co-operation on the customary terms has been so successful is proof that its policy commends itself to some dominant human tendency, and no very subtle analysis is needed to discover that after all the tendency to which co-operation appeals is our old friend self-interest, though it does masquerade under the disguise of benevolence. The co-operators would certainly not admit so much; but, even if they did, there would remain some solid benefit in the movement. It brings people into line, and trains them in industrial and commercial discipline; it teaches them how to act together, and shows them, though slowly and gradually, how important are the qualities of organisation and management, which in their own experience of industrial life they are apt to look upon from the under side and with too much antagonism. Lord Rosebery evidently thought it necessary to apply the spur. He did not refer to the vexed question of profit sharing, but he urged them to look round and see where they could apply their capital productively to the best advantage. This, indeed, is the crux of the co-operative movement at the moment. They have so much cash they do not know what to do with it. With the capital that they possess an enormously greater business could be safely carried on; and they know this, but, with praiseworthy caution, are chary about adventuring too far afield. Lord Rosebery pointed to previous experiments in co-operative farming, and urged co-operators to experiment anew. With the unfortunate collapse of Mr. Bolton King's experiment, carried on, as it was, with immense enthusiasm and much skill, the signs do not seem favourable for the adoption of Lord Rosebery's suggestion. The difficulty of co-operative farming is the difficulty of co-operative production in general—that is, the difficulty of choosing men. A farmer working on his own account gets rid at once of an incompetent labourer, but on a co-operative farm the incompetent is apt to remain. It is only fair to mention, however, that in some of the experiments it is said that an actual improvement in the character of the labourers has been observed.

Lord Rosebery mentioned an element which is of increasing importance for the future of the co-operative movement—that is, its reluctance to pay high salaries to officials, even where they are worth them. In some cases, doubtless, it is possible to get men to work for enthusiastic rather than pecuniary motives; but it is a question whether it is fair to underpay the man who is an enthusiast, and who therefore does his work well. The principle, pay and enthusiasm inversely proportioned, is suicidal, and to some extent, no doubt, this is the co-operative principle. In the early stages of the movement there were times when enthusiasts did the work, and did it for nothing; but now that the whole movement is established on a firm financial basis it will become impossible to get men to deal efficiently with large masses of capital without paying them fair salaries. The one abiding satisfaction in the co-operative movement is that it is all spontaneous and voluntary. It ha been founded by no Act of Parliament, it is constituted by no Royal Charter, it has grown from a small beginning to a great institution; sometimes on the eve of failure, but always triumphant in its self-helpfulness and independence. It has, to be sure, many of the weak points to which all mature institutions are subject, but when these are deducted there remains a monument of the energy and patience of the early co-operators, in the enormous industrial and commercial concern which has been the result of their labours.

THE BRITISH ASSOCIATION.

We have before us a copy of the Report of the British Association meeting last year at Newcastle-on-Tyne. The "success" of the meetings of this Association is gauged, it would seem, by the number of persons who attend—a criterion suggestive of a demonstration in Hyde Park. It is to be presumed that the 3,838 persons who were present at the Manchester meeting were influenced more by probabilities of fine weather, the Exhibition, and the facilities afforded by the locality, than by any expectations raised by the presidency of Sir H. Roscoe, or by the anticipated interest of any of the communications. But their very presence made a successful meeting, while Bath only attracted 1,984—a comparatively tame affair—and Newcastle came close to the average of the last nine years with 2,437.

The British Association meetings offer a twofold interest. On the one hand, the transient enjoyment of an assortment of lectures, papers, discussions, excursions, and picnics (the former being remarkable for a variety of subject, the latter no less "mixed" from a social point of view); and on the other hand, the real scientific work done. No doubt the attendance roll sufficiently indicates the "success" of a meeting in a certain sense; but the papers read, and the reports presented, are the only real elements of value, apart from the holiday aspect of the Association.

The British Association, as we have before pointed out, has its weak points. It may be compared not unaptly with the Royal Academy, who, in the first place, offer their best accommodation to 280 pictures—*i.e.*, seven from each academician—without any reference whatever to the merits of the picture or of the academician. After these, the productions of the associates, and selections from those of the public, are accepted. We need not mention the names of those who are always to be found "on the line" at the meetings of the British Association, but we cannot push the Academy analogy far, for in the one case a tangible picture is presented, while in the other there is often not even an old envelope with a few notes on the back, and if we wish to study the extempore "communication" in any other way than by listening to the speaker we must wait until perhaps long after the meeting has been dispersed, with the hope, frequently not to be fulfilled, of finding some of it in print. The Royal Society and the British Association are perhaps at the two extremes on the scale of real usefulness in publication of sound scientific work. Any one is welcome to send a paper to the former, and the "communication" is a paper, and not a mere discourse. It is referred to some high authority, who most carefully deliberates, frequently, we believe, calling in the advice of brother Fellows as to the true value and originality of the work which it embodies. The British Association, on the other hand, appoints secretaries for its different sections, and the chief business of not a few of these is to persuade members to "send a paper." After sufficient persuasion the member probably gives his promise and the title of his "paper." As the time draws near he is asked to send an abstract; should he do so it will probably appear in the report—a bulky volume published some seven or eight months after the meeting. Should he decide otherwise, he has only then to consider whether he is inclined to keep his promise, in which case he goes to the meeting and has "his say." A sufficiently interesting title and a chat with the secretary will secure the "acceptation of the paper by the committee," if the author is not a well-known faddist or advertising manufacturer. No shorthand reporter is in attendance, unless on behalf of some journal; no official cognisance is taken of any discussion that may arise, although, in most scientific societies, the discussions are often of a value at least equal to that of the paper. In our hypothetical case, which is not exceptional, the interesting title and the author's name appear in the report, and that is the end of the matter. Happily there are cases where the author attaches some value to his own communication, and he will send in his abstract, and perhaps a copy of his paper. He will in many cases prepare, and send to the meeting, specimens, or apparatus for experiments, or diagrams; he may secure the attendance of a reporter for some journal, in order that the discussion may be recorded; but after all he may find that the very men to whom he wishes to communicate his work are away at a committee meeting, or are at a meeting of a kindred section.

In the Report for 1889 we find, in Section A (Mathematical and Physical), no less than fourteen titles of reports and papers with no abstract, and no information is given as to whether they have been published elsewhere. The abstracts of seven other papers average less than four lines to each. The other sections are treated in a similar manner, with the exception of Section G (Mechanical), where papers containing new matter are seldom to be found, but where an opportunity is afforded for discussion. Here we find foot-notes referring to technical journals where abstracts, or the papers *in extenso*, are to be found. It may be pleaded that the expenses of printing will not allow any further space to be devoted to publication of the papers and reports, but a glance at the volume before us is sufficient to show that it is impossible to find any one reader who can be interested in all the immense range of science with which it deals. The volume contains 1,171 pages, exclusive of the publisher's advertisements. Of these, 124 are devoted to the rules, historical list of officers, balance sheet, lists of committees, the President's report, and another 171 contain the list of members and the index, making 295 pages, which are supposed to interest all members. The remainder, divided by the number of sections, gives about 110 pages to each. If these were issued separately, allowing, say, two sections to each member who applies (though he should not be restricted to this number), about two-thirds of the printing would be saved by this change alone. If double the present space were allowed for the reports and proceedings of each section there would still be a saving of more than one-third, still allowing an average of two sections to each member applying.

The limits of our space will not allow a discussion of the work of the committees. Much good work has been done by them, assisted by grants of money, but at the conclusion of their labours there is no one to whom to refer. An instance of this occurred last year, when the London Chamber of Commerce wished to push the B.A. standard screw thread, which was the outcome of a considerable amount of labour. But the committee had been dissolved, and there was no committee or individual who could render any assistance whatever. For more than eleven months of the year the British Association has no other abode than rooms shared by, or in connection with, the Royal Asiatic Society, the Society for the Promotion of Hellenic Studies, the Aristotelian Society, and the Numismatic Society, and other miscellaneous institutions. The officers are, with one exception, we believe, all honorary. Under these conditions we fear that it must continue to be rather an Association for the organisation of an annual scientific holiday, than for the Advancement of Science.

At about this time of year the committees begin to meet to arrange for the forthcoming autumn, and we trust that, though there may be some difficulty among eight sectional committees and sixty-five working committees, a general committee, and a council, in arriving at any useful conclusion, an endeavour will nevertheless be made to promote some solidarity and joint responsibility of the body as a scientific society, and that measures will be taken for properly recording the work done.

AFFAIRS IN JAPAN.

From information recently received from Japan, we learn that the new Foreign Minister of that country, who was formerly Ambassador in Berlin, does not intend to allow the matter of treaty revision to lapse. We have on several occasions indicated the difficulties in the way of a solution of the problem of treaty revision in Japan, and shown that these have arisen, in great part, from the dilatory obstructive conduct of the foreign Powers. There would have been no difficulty in settling the matter years ago if only a little reasonable common sense had been allowed to prevail, for then the Japanese Government would have agreed to terms which they will have great difficulty in accepting now, as they have to reckon with a public opinion which has been created in the country during the past few years. Every one knows that the Japanese have made great advances in industry, education, and legislation since the question of treaty revision was first raised, and, what is more, they have a very good—perhaps in some cases an exaggerated—opinion of that progress and of their present position. However that may be, there cannot be the slightest doubt that the new Minister of Foreign Affairs has

Digitized by Google

before him a very difficult task. On the one hand the foreign Powers will insist on foreign judges being appointed at least for some years, while, on the other, the Japanese people will not hear of the indignity of having foreigners sitting as judges in their Courts. In the meantime the Japanese Government is teaching the foreign Powers a few lessons as to the limits of their present extra-territorial rights. Two cases have recently arisen in which Portugal and Britain were concerned, in which the Japanese refused to allow subjects of those countries who had committed crimes before they came to Japan to be extradited under the ordinary extra-territorial powers. They pointed out that these only applied to offences committed in Japan. The British Minister had the good sense to see the reasonableness of the Japanese position, and applied for extradition through the usual diplomatic forms, instead of through consular jurisdiction, and his action has been approved by the British Foreign Office.

We mention this merely to show that the Japanese are not likely to stand dictation on these matters in the future, and it would be well for our politicians to study all the bearings of the problem. The *Times* put the matter very fairly quite recently when it said that the Japanese "have formed a clear conception of what law means, and of the sacredness of the rights which it conveys, and they are properly resentful at any attempted infringement of them. It is no more than natural that they should look with dislike on the treaty fetters with which they were once willing to be bound, and the need of which they now believe themselves to have outgrown. The maintenance of foreign consular jurisdiction in Japan is felt as a standing insult to the local administration of justice. Nor can the Japanese willingly endure to have the regulation of their customs tariff taken entirely out of their hands, and settled for them by foreign dictation. The country that wishes to stand well with them might do wisely to allow play to their somewhat recent national aspirations. England has a larger stake in Japan than any other country, so that it is the more needful for her to recognise the enormous changes which the last few years have brought about, and the practical consequences which they involve. It is quite true that the Japanese people are not yet quite so far advanced as they fancy themselves, and that their impatience of control has gone beyond its proper limits. But that they ask more than their due is no reason why England should persist in giving them less than their due. Treaties such as the late Japanese Ministry was willing to sign with America, and with the other Powers, might safely be accepted by Great Britain, when the time comes, as come it must before long, for Japan to be again in the mood to offer them."

Letters to the Editor.

PIG IRON WARRANTS.

To the Editor of "Industries."

Sir,—There is no doubt that the speculation in pig iron warrants has had a most prejudicial effect upon the iron trade, and while a few have made large profits, owing to special acuteness, severe losses have been incurred by a greater number. The action which you report is being taken by the British Iron Trade Association in the matter may, and it is to be hoped will, be of benefit. It is premature to form an opinion until their suggestions have been formulated, but I have grave doubts whether legislative measures can be devised which will effectually curb the speculator. Similar complaints to those which are now being made regarding warrants have often been heard about Stock Exchange transactions, but no remedy has been devised. In any case, even though the subject is a burning one at the present moment, undue haste must be avoided. To try and rush an ill-considered Bill through Parliament would probably only tend to make affairs worse instead of better.

Yours, &c.,
A User of Iron.

Glasgow, 27th May, 1890.

PIECE WORK.

To the Editor of "Industries."

Sir,—I would like to add a few words to those of your correspondent, "J. D. W.," in your last week's issue, on this subject. No complete statement has ever, to my knowledge, been made by the trades unions of their reasons for objecting to piece work. Half a dozen arguments have been put forward from time to time, each suitable to the particular occasion, but not always consistent with the others.

One elementary principle which is taught by a certain school of socialists is that the fair day's work of one man is as good as that of another. This is the school which delights in visions of a community where one half of the traits of human character and physique have been annihilated, and whose social machinery would be completely upset by an individual with only a moderate amount of laziness, of greed, of conceit, of stupidity, of improvidence, or even of ambition. It is difficult to foresee, if indeed it is worth while to consider, the result, in such a community, of some of the opposite characteristics—energy, cleverness, prudence. They might exist: their presence would not be so fatal to the scheme as the others, but there would be no inducement whatever to cultivate them, except for ethical considerations. Dragging down all to their level, and extinguishing every incentive to the progress of individuals, of which our national prosperity is the sum, these socialists desire for the whole community an insipid uniformity, which the trades unions would have in every workshop. No one who has served his time in shops where piece work is done, and has mixed at all among the men with whom he has worked, can have been blind to the envy with which a unionist often sees a non-unionist engaged on a bit of piece work.

As I have pointed out in another place, a young man just out of his apprenticeship is easily persuaded to join the union, and he feels that this is one mark, at least, of having reached manhood. Having no particular desire to do more than he need, and having the increase of wages to which he is then entitled, he takes but little interest in the piece work question. But after a few years, if he is worth anything, he will have acquired such skill that he can get through a day's work with less expenditure of energy. He may have a wife and family to support, he recognises the fact that he could with ease do half as much work again in a day (piece work statistics can show cases of double this, and more), and he finds himself fettered by the rules of his union. He could withdraw his membership, but not the subscriptions which he has been paying, week after week, for years. These represent to him simply so many payments of an insurance premium to a fund from which he will be entitled to draw when he is out of work or ill. If he were to throw over the union, and get good piece work employment, he could put by a quarter of his wages and live more comfortably, but he dare not take the risk of possible want of work or health.

Lord Bramwell said at the Bath meeting of the British Association that political economy "has made the workman a free man. He may employ himself in any work which he can get trusted to him. He may demand any wages he thinks right, refuse to work for less, and get all he can. He is no longer, by the mischievous laws of settlement, almost confined to the parish where he was born. He may go to any part of the kingdom in search of work. He is no longer subject to punishment for joining with his fellows to better his condition. He may combine with them and agree that they will, as a body, refuse to work unless their wages are raised or other demands complied with. His doing so is no crime, provided he does not violate the freedom and rights of others." Obviously, he has a right to impose on himself, and on others who voluntarily combine with him, abstinence from piece work, but considering the men who are put forward—I should say, who put themselves forward—as the representatives of the trades unions, it is as useless to hope to influence them on the subject, as to expect any good to come from a Royal Commission on piece work.

The unions are invaluable as insurance societies, and it is excusable if they are used as organisations to support common interests; but it is not easy to see any other hope for a solution of the difficulty than by the gradual education of the individuals to realise what are their true interests.

Yours, &c.,
Alex. P. Trotter.

Westminster, 23rd May, 1890.

COMPRESSED AIR TRAMCARS.

To the Editor of "Industries."

Sir,—We really cannot understand your correspondent, "Car." First, he says that our system requires a new roadway because we have to lay pipes. On its being pointed out that the pipes would be under the footway, he says he can see no difference between footway and roadway, and now he expresses astonishment that anyone could imagine that the taking up and relaying of tram rails on a different system, such as required for an underground cable, or for alteration of gauge, could possibly involve a new roadway. It is evident that "Car" has had no experience in these things. Let him just try it on, and the local authority will soon enlighten him. In answer to his question, we beg to inform "Car" that the gauge, on the Bristol Road line in Birmingham was altered before putting on the new electric storage cars. It was said that this was done merely to assimilate the gauge to other lines in Birmingham, and we are asked to believe that it was the merest coincidence that this was done just at the very time when the company were about to employ cars, the gauge of which was made, however, in order to make room for the accumulators.

As regards electric traction in America, it is apparent that "Car" is dazzled, like many others, with the flaming accounts published in the papers, which, he says, "fairly bristle with paragraphs." The stockholders who have so large a stake in the success of electric traction, and are naturally unwilling to give in until everything that can be thought of is tried, have evidently great faith in the efficiency of "paragraphs," and that they are justified in that faith is shown by the letter of "Car." Has "Car" taken the trouble to ascertain how many of the American cars are worked on the accumulator or storage system, and how many on the overhead wire system, which would never be admitted into the public streets in this country?

"Car" cannot understand "our theories of financial operations," which, he politely informs us, are "utterly absurd." To "Car" it seems absurd to suppose that a patentee, on seeing his invention nearly played out in his own country, should endeavour to get up a boom in other countries in order to sell his foreign patents before the bursting of the bubble. Oh, no! he would not dream of doing such a thing. At least, he would not if he did not know that the world is full of people possessing the simple faith of "Car."

"Car" refers to Mr. Baines' letter as proof absolute, but we can find nothing in it but assertions without proofs. Mr. Tittlebat Titmouse said that he could "prove" that he was the only son of his parents "by saying so truly," but this sort of proof is not generally considered good enough in the practical affairs of life. Mr. Baines says "the cost of renewals in accumulators is *estimated* by various authorities at from 1d. to 1½d. per car mile," but "estimated" is not good enough. In Brussels the maintenance of the accumulators alone was "estimated" at 3·51 centimes per car kilometre, but actually *cost* 9 centimes, or 14½ centimes per car mile. So much for the difference between estimates and actual results.

We will conclude by the following quotation from an article in the *Liverpool Daily Post* of the 27th May, referring to the report of Sir John Fowler to the Agent-General of New South Wales, on the subject of electric traction:—"One very significant remark is made by Sir John Fowler as to the cost of maintenance. He says, 'There is not sufficient reliable data to fix a lifetime for accumulators.' This is really the root of the matter as regards economy of working. We have frequently seen estimates of cost of repairs, but they all stop short before the period when substantial renewals would have to be made. When that point is reached, new apparatus is provided, not for the purpose of replacing the used-up apparatus, but 'to take advantage of the most recent improvements,' only it generally happens providentially that these improvements come just in time to avoid the renewal of the old apparatus, which is thus charged to capital instead of revenue account. Then with the new apparatus a fresh start is made in the repairs account."

We are really too busy to waste any more time in answering anonymous correspondents like "Car."

Yours, &c.,
Hughes & Lancaster.

City Road, Chester, 28th May, 1890.

JARMAN'S ELECTRIC CAR.

The electrically worked tramways in Great Britain are very few in number, but an addition will presently be made on the London Tramways Company's system, on which the Electric Tramcar Syndicate, Limited, 31, Lombard Street, E.C., have arranged to run several accumulator cars. The inventor of the system is Mr. A. J. Jarman, who has got one car now in readiness, with which private trips have already been made with successful results. Some considerable time back the same inventor made many experimental runs with a car, and the experience derived from these trials has resulted in the practical development of the present system. The stretch of line on which the cars are to be worked is from Clapham Common to Tooting, on which some 1 in 25 gradients are met with, but the cars do not seem to find any difficulty in overcoming them.

The car is of the same type as the ordinary horse cars on the line, with the exception that it stands a few inches higher. The accumulators are placed under the seats of the car, but instead of being put into position from the sides, as is the case at Barking, they are run in on trays from the ends. It is proposed to eventually use hydraulic plant for this purpose. As inconvenience would arise in inserting and withdrawing the cells simply through the hinged doors, corresponding doors are provided in the splash boards.

There are, in all, 52 double ebonite cells of the "E" type, 26 on each side, connected in series, the total weight being two tons. In order to provide ventilation for carrying off any fumes from the cells, hinged doors are placed at each end fitted with horizontal louvre boards. Access to the cells can be obtained from the interior of the car by lifting up the seats.

The motor is of a special and peculiar type. Two separate armatures are placed on a single shaft, so that one may revolve in one direction and do work, while the other revolves idly and dissipates heat acquired while running, by radiation in an induced current of cold air within the inert field magnet. Mr. Jarman's theory is that an electric motor, when applied to purposes of locomotion, cannot work efficiently when a single armature is employed, for the reason that greater power has to be developed in order to overcome the increased resistance when starting the vehicle from a position of rest than is required to maintain the motion at the required rate of speed. The motor has, as already stated, two armatures, and two bi-polar field magnets. It is carried in a steel frame, bolted to the body of the car, and also supported by the axles through the axle boxes. With a view to obtain exceptional power when making a start, the magnets have been wound in a special manner, termed the "gamut" winding. This consists in the cores being wound with layers of wire of varying resistances, and which can be either cut out of, or included in, the circuit by means of a suitable switch, the ends of each layer being led to the switch, so that each or all of them may be withdrawn or included as already stated.

The gearing is also special. A wrought-iron pinion, running at 650 revolutions per minute, is placed between the two armatures on the motor shaft. On the countershaft there is a mortice wheel, but the cogs, instead of being of wood, are of vulcanised fibre. Two flanges are placed an each side of the mortice wheel, and the cogs are sunk into slots. Holes are bored through the flanges on the pitch line, through each of which a pin is inserted keeping the cog in place. The size of the mortice wheel is such as to reduce the revolutions to 216. Another wrought-iron pinion on this countershaft gears into a second mortice wheel on the axle of the car, further reducing the revolutions to 90 per minute. These speeds obtain when the motor is running at its normal rate. The vulcanised fibre cogs have the effect of causing the car to run with a minimum of noise.

At either end of the car is a cylindrical case, containing the switch. The handle of the switch at the top of

Digitized by Google

the case may be revolved in either a backward or forward direction—corresponding to a forward or backward movement of the motor. This operates the switch, which consists of a wooden cylinder placed upon a metal spindle. On the surface of the cylinder are fixed circumferentially strips of gun-metal, of different lengths and widths. These are wide enough to form contact with any pair of contact tongues which represent the ends of the various layers forming the "gamut" winding. Between these strips are placed plugs electrically coupling the spindle with the tongues connected with the termination of the last layer that has been placed in circuit, a connection from the end of the spindle serving to couple the spindle to the brush or other part of the circuit so as to complete it.

At normal speed one of the armatures is doing work while the other revolves without performing work. At half speed the motor is in series, and in full speed in parallel. The cars will be worked for the Tramway Company by the Electric Tramcar Syndicate at a rate not exceeding 4½d. per car mile.

Reviews.

A Dictionary of Applied Chemistry. Vol. I. By T. E. Thorpe, Ph.D., F.R.S. Longmans, Green, & Co. 1890.

When the first volume of the new edition of Watts' Dictionary of Chemistry, under the editorship of Dr. Morley and Mr. Muir, was issued, the publishers promised a separate dictionary devoted to applied chemistry, to be completed in three volumes, and they have now commenced the fulfilment of this promise by the issue of the first part, which includes the subject matter to the end of "dyeing." This companion dictionary is essentially a separate work on chemistry in its applications to the arts and manufactures, and deals but sparingly with the purely scientific aspects of the science which are discussed in the other dictionary. Although produced under different editorship, the general method and plan of the two works is the same, and, what is perhaps more important, the nomenclature and notation adopted is practically identical; it is, therefore, easy to consult both dictionaries for the same subject when one wishes details of the theoretical and applied history of any chemical product. The two new dictionaries are thus meant to be complementary to one another, but it has been found impossible to avoid a certain amount of overlapping. This is more especially the case in the applied chemistry work, which, in order to place its articles in a complete form to its readers, has encroached on the domain of pure science and availed itself of many of the facts recorded in the sister volume. That this is done intentionally may be gathered from a comparison of the two articles on "atmosphere" in the two volumes. These are both written by Professor Thorpe, and we notice that in his dictionary he has given a kind of abstract of his article in the other work, and certain parts are reprinted (*e.g.*, the account of Dr. Percy Frankland's researches), while additional information is given on the technical parts of the subject. This completeness of the Dictionary of Applied Chemistry considerably increases its value, as its scope is sufficiently wide to make it suffice as the only chemical dictionary for the engineer and technologist, for which purpose it is admirably adapted. The publishers have, we believe, done well in thus dividing the science into two parts, for while it will be necessary for every class of chemists to possess both dictionaries, the three volumes on applied chemistry will find their way to the bookshelves of many engaged in the manufactures and industries which are only slightly connected with chemistry. Professor Thorpe has been exceedingly fortunate in securing the co-operation of many of the leading chemical specialists as contributors on subjects with which they are well posted. The rapid progress in many departments of applied chemistry in recent years makes it no easy task for an editor of a dictionary devoted to this subject to insure that his subject matter is well up to date, but from our examination of the volume under review, we have to congratulate Professor Thorpe in succeeding to keep his information free from such criticism.

The editor in the preface states that special attention has been given to the compilation of trustworthy patent lists, and of these the one relating to azo-colouring matters includes a summary of the more important British and foreign patents taken out from 1878 to October, 1888, which will be found of great value to those engaged in the colour industry. Numerous references are given to the *Journal of the Society of Chemical Industry*, but we should have been glad if lists of the papers and abstracts in this important journal had been given at the end of several of the articles. The wide popularity of this journal is, no doubt, due to it forming an admirable work of reference, and as it is now recognised as the leading journal for applied chemistry in the English language, a dictionary might with advantage refer to it for further details on most of the subjects, and thus be able to devote more space to foreign literature which has not yet found its way into English print. This is rendered still more necessary from the vastness of the subject and the small amount of space which the publishers are devoting to its treatment.

A Treatise on Chemistry. Vol. III. Part II. New Edition. By Sir H. E. Roscoe, F.R.S., and C. Schorlemmer, F.R.S. London: Macmillan & Co. 1890.

This is a new edition of the volume of the author's well-known treatise on chemistry, which treats of the more complex members of the "fatty" series of organic compounds. Since 1884, when this part of the work was first published, several important researches have been carried out, with the result that our knowledge of this branch of organic chemistry has been considerably increased. The present volume includes such recent work as the researches of Curtius on the fatty diazo-compounds, of Kiliani on the constitution of the members of the sugar group, and of Emil Fischer on the syntheses of members of this series. Our knowledge of so-called brewing chemistry, as shown by the work of Brown, Heron, and Morris, finds a place in the present volume, where the starches and dextrine are discussed, and the poly-methylene ring compounds of Dr. Perkin, jun., are also added to the list of bodies described.

The authors, by thus keeping their text-book up to date in the different branches, are determined that it shall continue to maintain its place as the chief of chemical text-books. And although, by gradually increasing in size, it is growing to the dimensions of a dictionary, their interesting historical notices of compounds and abstracts from classical papers render it far more pleasant reading than some of the newer dictionaries of chemical science.

Magnetism and Electricity. By A. W. Poyser, M.A. Longmans, Green, & Co. 1889.

This excellent little volume of some 250 pages was written primarily, as the author informs us in his preface, to meet the requirements of students preparing for the elementary stage of the Examination in Magnetism and Electricity of the Science and Art Department, but though the lines of the syllabus drawn up for that examination are pretty faithfully followed, the author has not hesitated to introduce additional matter where it seemed desirable; and, indeed, several chapters are devoted to the treatment of subjects which are not included in the syllabus of the examination. This has been done with the object of providing a suitable course for a year's work at school, and the author has, on the whole, been exceedingly successful in carrying out his plan.

The specially valuable feature of the work is that it is cast entirely in the experimental form, the volume consisting of a series of descriptions of experiments to be actually performed by the student, followed by the inductions to be made from the observed results.

Any teacher of physics worthy of the name would see almost at a glance, independently of the author's statement in the preface, that the book is the outcome of practical work in teaching, and we most emphatically endorse the author's opinion that the only way for a student to gain a real knowledge of magnetism and electricity, or any other branch of physics, is to perform the experiments himself, to regard his text-book or the lectures of his instructor as supplementary to and explanatory of his experimental work, instead of, as is unfortunately most generally the case, the practical experimental work being regarded as a mere supplement to the didactic teaching, and, though advantageous, not absolutely essential.

The book appears to contain very few faults, but there are one or two points in which improvement may be made.

Weber's theory of magnetisation is supported by such a mass of experimental evidence that it may be regarded as raised to the rank of an established fact. Most of the conclusions, moreover, on which it is based are so easily investigated experimentally, and it is so great an assistance to a beginner in fixing his ideas, that it certainly ought to find a place.

In the opening chapter the unfortunate statement is made that when two opposite magnetic poles are placed near together they neutralise each other. A statement of this kind, if given by a student in the South Kensington examination, would result in his answer receiving comparatively low marks, and it has the far more serious defect of confusing his ideas. It ought to be clearly explained that the result is that they neutralise each other's actions on a neighbouring magnetic body by producing opposite inductive effects, a very different explanation from what a student would infer from the author's statement.

The terms "frictional electricity" and "voltaic electricity," though retained in the South Kensington syllabus, are not happy ones, as they tend to perpetuate the erroneous idea that there is a difference in kind between the electricity generated by friction and by chemical action respectively. The author appears to have felt this to some extent, as he employs the term "frictional electricity" to denote a static charge, and "voltaic electricity" as equivalent to an electric current, but this is only introducing further confusion. Experiments should also be given showing that the charge or current is of essentially the same kind, whether obtained from friction or chemical action. A clear understanding of this is of fundamental importance to the learner, and, moreover, it is very properly expected by the South Kensington examiners. These blemishes, however, though by no means unimportant, are hardly sufficient to detract seriously from the value of a book formed upon so excellent a plan, and which, moreover, is on the whole so well carried out.

The book is well got up and illustrated with a large number of well-executed diagrams and representations of apparatus.

Newbigging's Handbook for Gas Engineers and Managers. Fifth Edition. London: Walter King. 1889.

This well-known handbook has quickly run through the earlier editions, and the author in the present edition has made considerable additions to the text, which will make it still more popular with that class of readers for which it is intended. We congratulate Mr. Newbigging on the success of his endeavour to keep his handbook well up to date, and on the production of such a practical and useful work of reference. The capital employed in the manufacture of gas at the end of 1888 amounted in this country to the large sum of £62,778,000, which figure will represent the extent of the manufacture of gas in the United Kingdom, and shows what rapid strides the industry has made since Pall Mall was first lighted with gas in 1807, and since the incorporation of the Gas Light and Coke Company by Act of Parliament in 1812.

In the present edition of his handbook, Mr. Newbigging has devoted considerable space to a *résumé* of the different methods proposed or in use for the removal of the impurities in coal gas, and, while giving details of the older processes in which lime and hydrated peroxide of iron are used, also gives the merits and demerits of the lime, spent lime, and oxide of iron purification process of Dr. Odling, and the newer plans based on the use of pure oxygen, of caustic soda and sulphide of sodium, of caustic ammonia and carbonate of ammonia, and that which is now being tried at Belfast and known as Claus' process of purification by ammonia gas. These methods are discussed fairly by the author, in a manner which gives the gas manager sufficient knowledge of the various processes to enable him to decide on the suitability of any one of them for his own particular works. The testing of gas, as prescribed by the Gas Referees for the London district, is also fully discussed, and the proposals for altering the

Digitized by Google

present unsatisfactory standard of light. The chief value of the book will, however, be found to lie in the technical details of the construction and dimensions of the plant necessary in a well-constructed gasworks, and the author's long experience in his profession gives him a store of statistics, which will be found of especial value to the younger members of the profession. The gas engineer or manager who has served his apprenticeship in one of the older gasworks, and is suddenly transplanted to a fresh locality in which newer or larger gasworks have to be erected under his direction, will find in this handbook data which he could only otherwise acquire by consultation with men of greater experience or by laborious search through the chemical and trade journals, and Mr. Newbigging has therefore earned the thanks of all the younger men in giving them a handbook which will supplement their knowledge and give them an amount of confidence which otherwise it would be almost impossible to acquire. Not the least interesting part of the book are the numerous trade recipes which are dispersed throughout, and which are certain to be found of great use in large works.

CIVIL AND MECHANICAL ENGINEERING POPULARLY AND SOCIALLY CONSIDERED. By J. W. C. Haldane. Second Edition. London: E. & F. N. SPON. 1890.

We noticed Mr. Haldane's book at considerable length when it first appeared, and the favourable opinion which we then expres ed about it has been fully justified by the appreciative manner in which it has been received by the press and the public. We pointed out that although it was written in a free and unconventional style, it was likely to convey more useful information to its readers than many more formal treatises, and especially on those subjects relating to everyday practice. It is just the sort of book to put into the hands of a young man who has not decided on the trade or profession he is going to adopt, as it gives a very clear idea of the everyday work of engineers in different departments.

The present edition has been revised throughout, and much fresh information is given concerning the latest phases of engineering. Even the stories are revised and brought up to date. For instance, the one about the Japanese engineer who somehow or other forgot, at a critical moment, his "formula for stopping the engines," is counteracted by a statement of the work done by Japanese students in this country. We are inclined to think that the above-mentioned story is a myth, and only an exaggerated way of stating the tendency of Japanese to attach undue importance to book knowledge. At least during a considerable residence in Japan the writer was never able to get any good foundation for the incident referred to. Throughout the book reference is made to the latest developments in engineering. The two last chapters especially should be studied for those relating to marine engines. We think, however, the explanation of the causes of the higher economy of multiple expansion engines might have been a little more scientific. What is given can only be looked upon as a first approximation. In conjunction, however, with the practical information which is found in the book, and the illustrations, it may lead those who read it to a more thorough study of the very complex phenomena connected with the use of steam in such engines. We have no doubt that this edition of Mr. Haldane's work will be as popular as the last. We would commend it to the attention of teachers as a very suitable book to be put into the hands of boys leaving school. In saying this we do not of course mean that it is essentially a boy's book, for we think that experienced engineers will find much useful information in it.

THE ROMANCE OF MODERN INDUSTRY. By James Burnley. W. H. ALLAN & Co London. 1889.

The proper use of the imagination is a factor which is very much neglected in modern education. The modern practical man insists on his son being taught facts—nothing but facts; and the consequence is, that the young men of the present generation are very often wanting in that energy and "go" which do more to make a man successful than any amount of facts or technical instruction of the ordinary dry-as-dust kind. Enthusiasm, kindled by a proper use of the imagination, has been a very powerful agent in advancing progress in science and the industrial arts, and a great deal of romance is to be found in the history of that progress, and it is of this romance which Mr. Burnley attempts to give a sketch in the book before us. He reminds us that the trade annals of the nineteeth century are full of romantic episodes, and that the imagination is always impressed by stories of men who have carved their way from obscurity to wealth; while the stories of failure and disaster, by which the commercial record is darkened, are no less enthralling. The object of his book is to afford finger-posts to guide those who wish to explore the industrial field to those paths which lead to success, and to warn them against those which lead to failure, and that not by abstract teaching, but by concrete examples of success and failure both in individuals and corporations. The introductory chapters of the book are such as will captivate young men and raise their imaginations, giving, as they do, an account of the romance of steam and machinery, and of industrial Utopias which have been proposed at various times, and some of which are now being revived. The chapter on "Wealth in Rubbish" will bring their imaginations to bear on small matters, and enforce on their minds the truth that dirt is only matter in the wrong place, and that it very often turns out very important matter—in fact, that what was formerly considered rubbish very often now furnishes the chief profit of the industry with which it is connected. The romance of patents will further impress on the reader the necessity for attention to economy in small things. We cannot follow Mr. Burnley through the whole of his twenty interesting chapters, but may mention the titles of a few of them. He treats of gigantic businesses, working men who have risen, commercial crises and failures, some great strikes, wars and their effects on trade, industrial accidents, international trade dealings and British industrial centres—all of which are of great interest, and convey a mass of most useful information, which is well worthy of careful study. Such books as that of Mr. Burnley are well calculated to supplement the more formal instruction which is now given under the name of technical education.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

AT the meeting of this Institution on the 22nd inst. the discussion was continued on Major Cardew's paper, "The Treatment, Regulation, and Control of Electric Supply by the Legislature and the Board of Trade."

Mr. A. A. Curtis Hayward remarked that Major Cardew's paper touched lightly on the appointment of electric inspectors. He considered the vesting of such appointments for the metropolitan district in the London County Council a regretable incident, and was glad to note that in future orders the right of appointment would be vested in the Board of Trade. The appointments were, he said, at present very important, for the public had been somewhat alarmed by the sensational accounts of accidents in America. The knowledge that properly qualified inspectors were to be appointed would tend to restore confidence and give great satisfaction to the community. His opinion as to the future importance of electric inspectors did not coincide with that of Major Cardew, for he believed they would form a case of degeneration rather than one of development. He could not agree with Mr. Crompton about over-legislation, and thought the latter gentleman overstated the case when he said that the gas works clauses might have been easily modified to cover electric supply. A real need for a special Act existed, for there were many subjects in electric supply, such as overhead wires, &c., which were quite foreign to gas distribution.

Mr. Emile Garcke said he was not prepared to discuss the details of the regulations in the face of Major Cardew's statement, that criticism from even a high electrical authority might be erroneous. He would rather confine himself to the historical facts. The parliamentary history of electric lighting was unique, and the rapid changes that had taken place in the industry were phenomenal. The first Select Committee, he said, was appointed in 1879, when the commercial possibility of incandescent lighting was unknown. Its fair report encouraged contracting firms to promote Bills in Parliament. In the spring of 1882 another Select Committee was appointed, and in the same year the memorable Act of 1882 passed. Although its results were lamentable in one respect, he thought it not an unmitigated evil. After detailing the various attempts to remedy the defects of that legislation resulting in the Act of 1888, he pointed out that no time had been lost, and that progress had been comparatively rapid. He laid great stress on the exceptional character of the legislation even of the amended Act, and said that no other industry had been placed under such adverse conditions, excepting perhaps that under the Tramways Act, but even this was much more favourable to the contractors than the Electric Lighting Act of 1888. The exceptional character arose from the fact that Parliament refused to put electric lighting corporations on anything like the same footing as gas companies, and thus the former had to compete on very unfavourable terms. It was in the power of the gas companies, by foregoing their dividends for a year or two, to completely crush electric companies, for, in addition to their power to pay accumulative dividends, they had the advantage of practically perpetual tenure, whilst the electric companies were limited to forty-two years. As regards local authorities, he complained that, according to present regulations, it was in their power to stifle electric lighting, and, as many of them were largely interested in gas, he argued that it was not right that the electric companies should be placed in such a difficult position. To show how vexatious local authorities may be, he quoted a case of a central station established in the early days of electric lighting. The work was carried out satisfactorily by overhead wires until such time as regulations were issued by Board of Trade stating that all wires must be put underground. In the face of the twenty-one years' purchase clause it was financially impossible to comply with the regulations. When the amended Act was passed in 1888, the company applied for a Provisional Order, but were opposed by the local authority, which was at that time negotiating for the purchase of gas works. He was not aware that any other kind of vested interest had been similarly treated.

Mr. K. L. Murray said that in Victoria they had no Acts of Parliament or regulations to control electric supply, and until recently they had no rules. Last year, however, the Victoria Institute of Engineers had drawn up a set of rules based largely on those issued by this Institution and by the insurance companies. An Act of Parliament, he said, was now expected, and the present discussion would aid in framing the Bill. A knowledge of what to avoid, as well as what to do, may, he hoped, lead to a model Act, from which, perhaps, the mother country might copy with advantage.

Captain Rowan said that in Australasia, where he had been engaged in introducing electric lighting, difficulties arose from want of legislation. No public body had power to give authority to lay mains or to erect overhead wires, &c., and in consequence matters had come to a deadlock.

Mr. H. Human disagreed with what Mr. Crompton said about the injustice of compulsory supply at either of two pressures, and pointed out that a grocer who made up his tea or sugar in pound or half-pound packages had not a monopoly granted to him for forty-two years. In his opinion, there was no particular hardship to the undertakers in the regulation, whilst it was a distinct boon to customers. He thought Mr. Crompton, in his remarks about the gas and water companies, had overlooked the fact that they had been sources of complaints for years. His comparison of electricity with gas and water was not legitimate, for in the former case, where such a subtle agent as electricity was dealt with, consumers were much more at the mercy of undertakers. In America, he said, where the industry had not been hampered by legislation, there had been so many accidents and fires that the public were now appealing for control, and the wish had been expressed that a body analogous to our Board of Trade was in existence there. In conclusion, he said that the Acts of Parliament, if harsh, were necessary, and he hoped that those who advised the Board of Trade would hold the scales equally between consumer and undertaker.

Mr. A. Siemens said it should be borne in mind that the objects of the legislation were twofold—1st, to empower electric supply companies, &c., to lay mains in the public streets and conduct the business of supply in a manner recognised by law; 2nd, to recover charges for supply made to consumers. Both these aims were intended to confer powers on companies which otherwise they could not possess. Originally, he said, the Board of Trade had power to grant Provisional Orders without the consent of the local authority, but in the later development neither licences nor orders could be granted without such consent being first obtained.

Mr. J. S. Fairfax hoped that no hard and fast line would be laid down as regards the kind of instrument to be used at testing stations.

Mr. E. L. de Segundo did not agree with Mr. Crompton about the Board of Trade having gone too far; in fact, he thought it had not gone far enough as regards protection of the public by making regulations for insulation tests. He knew a case where a 1,000 volt circuit was tested at 100 volts, and he pointed out that to test a steam boiler intended to work at 100lb., with water pressure at 10lb. would be considered ridiculous. The testing of house wires was also very important, for in one case he was assured that there was no defect in the insulation for in the contractors' tests no indication of a leak was obtained. On applying Evershed's ohmmeter with about 100 volts a dead earth was indicated.

Mr. Mordey, in referring to the question of safety devices, said it was time the subject was settled. The method of earthing the secondary was, in his opinion, perfectly safe. Great opposition had been made, particularly by the insurance companies, to its adoption, but the reasons for such objections were not forthcoming. As far as he could see there was no danger whatever with the secondary volts at 100, for by earthing the middle of the secondary the greatest difference of potential possible was 50 volts. Besides, the method had also the advantage of weeding out all rotten installations.

Digitized by Google

THE TREATMENT OF SEWAGE

By the Carbonised Refuse System, as Designed by the Rivers Purification Company, Limited, Leeds.

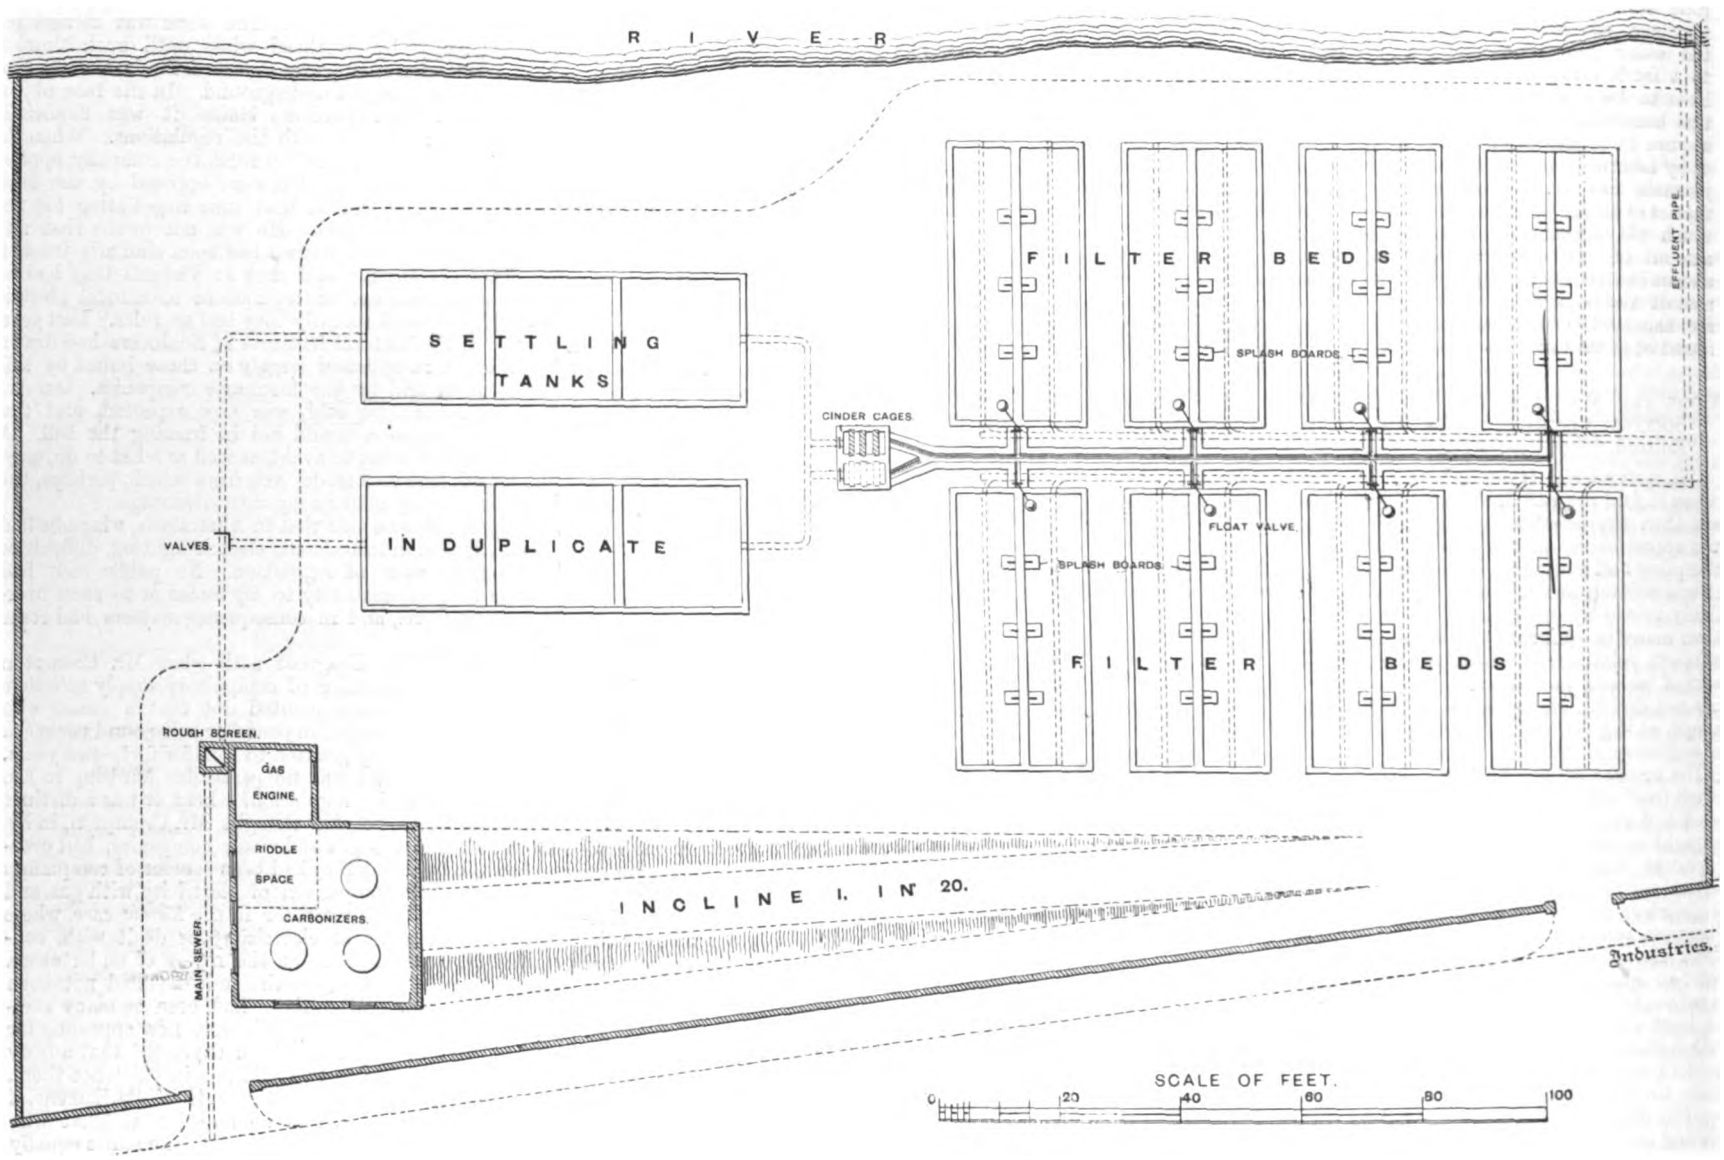

Fig. 1.—General Plan of Sewage Plant.

They had used the method on the Continent, and found it quite successful. The fuses, however, often went, owing to persons inserting penknives, &c., into the switches, for the object of obtaining agreeable medical shocks. As regards the Cardew device, he pointed out that its cost was not an unimportant item; moreover, it was automatic, and might not go off, and generally the fewer automatic arrangements there are about an installation the safer it is.

Mr. A. P. Trotter inquired what excess of current was required to let the fuses off, to which Mr. Mordey replied that about 20 per cent. above the normal was the ordinary average. In his opinion such currents could not give rise to fires.

Dr. Fleming asked what occurred in the case of an earthed secondary when the primary was also earthed. In Italy, where they had had considerable experience in alternate current distribution, the tendency was in the opposite direction, for the greatest care was taken to perfectly insulate both primary and secondary circuits. He himself had used an earthed secondary at the Inventions Exhibition, and had found no difficulty, but he wished to ask Mr. Mordey what his experience was. In reply, Mr. Mordey said that no difficulties had been met with.

Major Cardew, in reply, pointed out that the Board of Trade could not adjust or redress any wrongs, for such changes in the law must be made by Parliament. With respect to the declaration of pressure at consumers' terminals, he said this was rendered necessary by the introduction of transformers, for it was more difficult in such cases to know the fall of pressure in the distributing mains than in continuous current distribution. He then read the following draft, which is to be inserted in the new model orders:—"Before commencing to give a supply of energy to any consumer, the undertakers shall declare to such consumer the constant pressure at which they propose to supply energy at his terminals. The pressure so declared at any pair of consumers' terminals shall not, except by agreement, be greater than 115 volts, or less than 45 volts, if continuous, or the equivalents thereof respectively, if alternating, and shall not at any time be altered or departed from, except in consequence of any authorised alteration of the corresponding standard pressure. In distribution on the three-wire system the central terminal shall for the purposes of this regulation be considered to form a pair with either of the outer terminals, and similarly for multiple wire systems, and, in the case of a transformation of energy on the consumer's premises, the undertakers shall give the consumer the choice of a supply at either of two pressures, one of which shall be approximately half the other, and in such case the pressure so chosen by the consumer shall be the declared constant pressure." In drafting this clause, he said, advantage had been taken of the flexibility of the transformer system, in the interest of consumers. Mr. Shoolbred's questions with regard to meters were answered in the paper itself, for he would there see that they were to be certified by a local inspector, and be of a pattern approved by the Board of Trade. Mr. Murray's remarks about contacts between telephone and electric light wires needed careful consideration, for this was one of the chief sources of trouble and danger where high pressures were used. To Mr. Human he pointed out that the issue of a Provisional Order conferred no monopoly whatever. In reply to Mr. Siemens, he could not say why the change respecting the consent of local authorities had been made by Parliament. Such, however, was the case, and the Board of Trade could not dispense with that consent except in very special cases. As regards testing stations, he thought the arrangement he had suggested would be more satisfactory to the general public than the use of pilot wires and instruments fitted in central stations. To Mr. Fairfax he explained that the reference to dial instruments in pillar boxes was intended for indicating and not for recording instruments. Speaking of safety devices, Major Cardew said the plan of earthing the secondary got rid of some defects when the earth connection was substantial, but he thought the fire risks were increased by such a procedure. He had heard of fires being caused through a small leakage current having gradually charred wood, and ultimately set it alight. The apparatus bearing his name was, he said, admittedly automatic, but its action depended only on gravity and electrostatic attraction, and neither of these were likely to alter.

THE CONLEY-LANCASTER PROCESS FOR EXTRACTING IRON FROM ORE.

As the direct extraction of iron from the ore in a malleable state is the most ancient method known of obtaining this metal, the Hindoos having carried on the process from time immemorial, it would seem somewhat anomalous that the announcement of any invention to supersede the blast furnace is regarded, if not with suspicion, certainly with much indifference. How else can we account for the fact that new enormous blast furnaces are being erected, and old ones enlarged, when it has become a matter of history that an ironworks in Pennsylvania has been making steel by the direct process (and thereby doing away with the blast furnace) for a year past? Some of the finest bridge plates in the United States are being turned out from the Carbon Works where, according to the *Journal of the Society of Chemical Industry* (March, 1890, page 296), coke is broken

Digitized by Google

into small pieces and soaked in thin milk of lime, when it is found to answer all purposes. All the impurities of the ore are fused, the oxygen combined with the iron joins the carbon of the coke, passing off as carbonic acid gas, and leaves the impurities in a shape that they can be eliminated, the iron remaining in a malleable form.

Nevertheless, as a matter of fact, it is not without good reason that the designation of "direct process" has also been conferred on the manufacture of ingot iron and steel by the introduction of the molten metal from the blast furnace, either into the Bessemer converter or into the Siemens furnace. It is difficult to conceive of a more economical method for obtaining the metal from the ore in a malleable state, especially where, besides, Gjers' soaking pits are employed. Certainly no process involving two separate operations would seem at first sight able economically to dispense with the blast furnace as the initial step. Where the ore is found in the form of small particles, as in the case of the magnetic sea-sand so abundantly met with in Canada, which is so difficult to deal with in the blast furnace, it is possible that the employment of horizontal closed retorts, "so constructed that the ore can be stirred by a mechanical device, whilst hydrocarbon gas, charcoal, or coke is mingled with it for its purification," may prove to be the most practical way of dealing with it. The process is certainly valuable if, as Messrs. Conley & Lancaster claim, "it deoxidises, desulphurises, dephosphurises, and otherwise purifies the iron ore." In this respect these retorts would seem to perform the function of the Siemens rotator, the malleable iron obtained from which apparatus yields, upon analysis, carbon, 0·15 per cent.; sulphur, a trace; silicon, 0·4 per cent.; phosphorus, 0·05 per cent.; manganese, 0·201 per cent.; and iron, 99·198 per cent.

Really these retorts may more properly be said to replace the rotator of Sir William Siemens than the blast furnace, for the two appliances have one and the same end in view, namely, to furnish a metallic product for immediate use to be melted down in the open-hearth furnace. True, in the case of the Siemens rotator, the flame comes into contact with the charge, whereas, by working in closed retorts, such as the Conley-Lancaster, the formation of iron-containing slag is in a great measure guarded against, and thus a serious source of loss is obviated. It is mainly in this direction that the advantages of the new process would appear to exceed those of the rotator. Some ingenuity is exercised so as to prevent the oxidising action of the atmosphere during the operation of transferring the product of the retorts into the Siemens furnace. "When the treatment has reached perfection the retort mouthpiece door is opened by simply raising it, and is held in position by a catch while the retort is being cleansed. The cap covering the mouth of the chute is then removed, and the product of the retort is as rapidly as possible hauled into the chute, which is instantly closed when the removal is finished. This operation must be so conducted that it will expose the purified and deoxidised ore as little as possible to the oxidising action of the atmosphere. The purified ore within the chute is then run off into a closed vessel through a spout. The vessel is then hoisted and held above a depression on the top of the open-hearth furnace. A cap is then removed, and the valve of the vessel is opened, allowing the ore to pour into the molten bath within the furnace."

From some figures before us, which Mr. Lancaster indorses, the cost of producing steel in 4in. billets, by the Conley-Lancaster direct process, in either the United States or Canada, is 21·05 dols. if sea-sand ore is employed, or 24·05 if the steel is made from mined rock magnetic ore. As the selling cash price per ton in New York at the time of 4in. billets was from 38 to 40 dols. per ton, there would appear to be a good margin for profit in the process.

THE CARBONISED REFUSE SYSTEM OF SEWAGE TREATMENT.

We illustrate above and on page 522 the plant which the Rivers Purification Company, Limited, 9, East Parade, Leeds, propose to use for the sewage treatment of towns with a population of 10,000. This process has the advantage of dealing with the dry refuse and dust, as well as the sewage of the town, and by not employing any chemical treatment other than the carbon filters, which are charged with the carbonised dry refuse, appears to possess economically advantages over the older processes. The method of working is as follows:—Dry town refuse is taken up an inclined road, and deposited as required in a carboniser of the form shown in Fig. 4. The animal and vegetable matter contained in the refuse is reduced to charcoal by a process of slow combustion. The carbonisers are fully charged with the refuse, where it remains until the whole mass is thoroughly charred.

THE TREATMENT OF SEWAGE

By the Carbonised Refuse System.

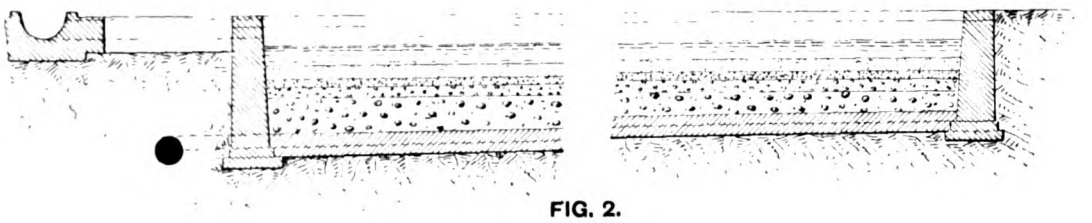

FIG. 2.

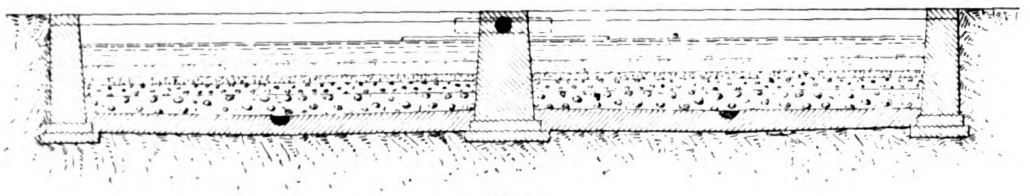

FIG. 3.

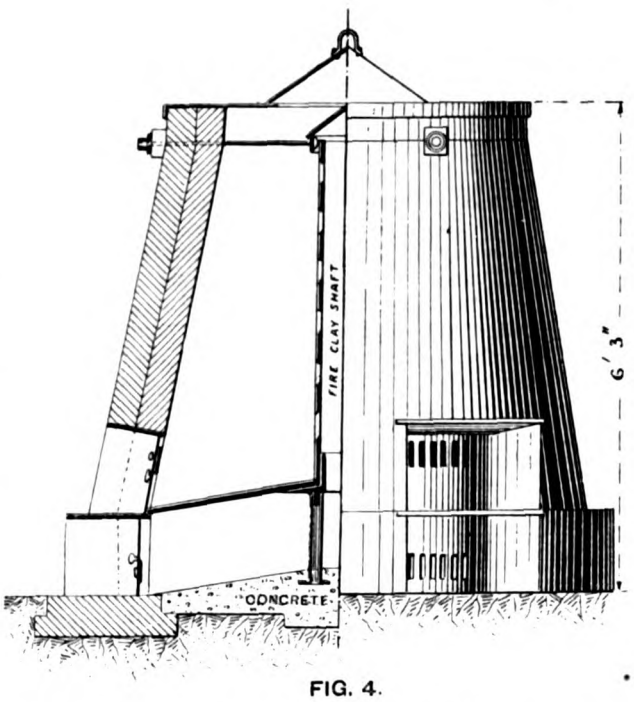

FIG. 4.

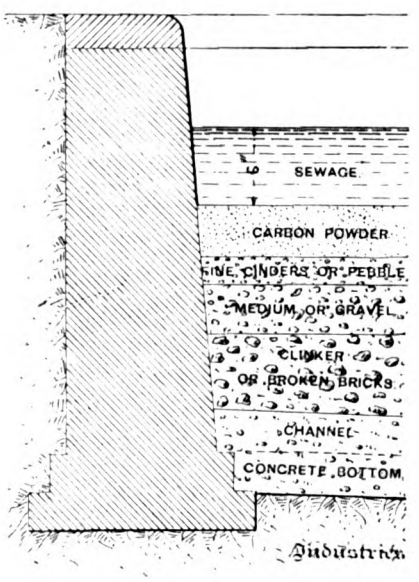

FIG. 5.

The carbonised material is then withdrawn and riddled by means of a circular riddle. Cinders and clinker are laid on one side for use in forming the bottom layers of the filters to be hereafter described. After the filters have been constructed the clinker and cinders will not be required for the filters, but may be utilised for making mortar, road repairing, or may be tipped in any suitable place without any fear of creating a nuisance. The lower layers of the filters may, where convenient, be formed of broken stones or bricks, gravel, and fine pebbles. The finer carbonaceous material, composed principally of charcoal with a small percentage of ash, is used as a filtering material by being placed as an upper layer, 4in. thick, upon shallow filter beds. The method of forming the filters will be readily understood upon reference to Fig. 5. Fig. 1 shows the plant required for a town of 10,000 population, and Figs. 2 and 3 show longitudinal and cross sections of a filter bed. The method of treating the sewage is briefly thus:—It is first passed through a screen which holds back the larger floating substances, after which it is passed through three settling tanks, and thence through three wirework cages filled with cinders of various sizes. The settling tanks and the cinder cages remove the bulk of the solid matter from the sewage. The clarified liquid then passes on to and through the filters previously described, and the effluent, as shown by analysis, is a remarkably good one.

Each filter bed is controlled by a valve connected with a clough, which prevents more than 6in. of sewage being upon the filter at one time. The sewage is distributed on to the filters by means of branch pipes connected to a central pipe built into the middle wall dividing the filter. Under each branch is placed a floating splash board, which prevents the sewage damaging the surface of the filters. After a filter has worked 24 hours the flow upon that particular filter is diverted to another one at rest. To facilitate the cleansing of the filter put out of work, any sewage remaining upon it is run off by a valve provided for the purpose on to the spare filter above named. As soon as the filter put out of work is sufficiently drained a thin film which forms on the surface is removed by means of a mechanical contrivance called a scum plough, a little fresh carbon is added, and the filter is again ready for work. A filter of 100 square yards can be cleansed and prepared for work in about ten minutes. The solids deposited in the settling tanks are mixed with the skimmings of the filters, the result being a portable manure, upon which the company have not fixed any great value. It will be noticed that this manure is not mixed with lime or other chemicals, and, therefore, is very different from the sludge obtained in similar processes. If it is of a stable nature, and not prone to undergo any fermentative or putrifying change, it should be a useful nitrogen food for cereals and grass. We should imagine that the filter beds would require to be renewed from time to time with fresh carbonised refuse in order that the effluent may be of a constant standard of purity. The land required for this process is one acre for each 20,000 population, which is only $\frac{1}{200}$th part of that required for broad irrigation, and $\frac{1}{10}$th part of that necessary for the combined process of chemical precipitation and land filtration. The company guarantee in their contract an effluent the purity of which shall come within the standard laid down in the Fifth Report of the Rivers Pollution Commissioners.

It is not absolutely necessary that in all cases the refuse be taken to the sewage works. Where the outfall is inconveniently situated with regard to the town, the refuse could be carbonised at any suitable point, and the carbon only delivered to the company at the purification works. The refuse, for instance, might in some cases be carbonised at the gas works. In towns where destructors are already in existence they, at no great cost, might be converted into carbonisers.

THE PHYSICAL SOCIETY.

At a meeting of this Society, held on the 16th inst., Lord Rayleigh exhibited and described an arrangement of "Huyghen's Gearing in Illustration of Electric Induction." This gearing consists of two loose pulleys mounted on the same axle, with an endless cord laid over them, the loops or bights of which carry weighted pulleys, whose planes are parallel to the axis on which the upper pulleys turn. If one of the latter pulleys be started to rotate the other turns in the opposite direction until such time as the speed of rotation of the first one becomes constant. Whilst this constant speed is maintained the second pulley remains stationary, one weight being raised and the other lowered; but on retarding the motion of the first pulley the second commences to turn in the same direction as the first. It will be noticed that the phenomena are analogous to those which occur in electric induction, where starting or increasing a current in one circuit induces an opposite current in a neighbouring circuit, whilst decreasing or stopping a current induces one in its own direction. Lord Rayleigh pointed out that in this apparatus there is nothing strictly analogous to electric resistance, for the friction does not follow the same law. The analogy, he said, was complete as regards there being no change of potential energy, and the mathematical equations for the kinetic energy of the system are precisely the same as those given by Maxwell for electric induction.

Dr. S. P. Thompson then made a communication on Dr. Kœnig's "Researches on the Physical Basis of Music," in the course of which Dr. Kœnig performed numerous novel and interesting experiments, clearly illustrating the subject of beats and timbre to a crowded audience. He defined "harmonics" by tones whose frequencies are true integral multiples of their fundamental. This is distinctly different from the theory of the "upper partial tones" of Helmholtz or the "overtones" of Tyndall. As to the main question whether beats, when sufficiently rapid, blend into tones just as primary shocks do, Dr. Thompson briefly recalled the various arguments for and against such an effect, and then Dr. Kœnig proceeded to experimentally prove the affirmative. Taking two forks tuned to 2,048 and 2,304 vibrations respectively (ratio 8:9), and sounding them simultaneously, the middle C of the piano (256) was distinctly heard. The same beat-tone resulted from forks having frequencies in the ratio of 8:15, whose negative remainder was 256. Various other tones were sounded simultaneously in pairs, and in all cases the corresponding beat-tone was clearly recognised by the audience. Dr. Kœnig had constructed steel bars of approximately rectangular section, whose periods of vibrations were different in two directions at right angles. Striking one face of the bar a certain note resulted, whilst a blow on an adjacent face produced a different one. When the bar was struck on the edge joining the two faces *both the notes* could be heard as well as the beat-tone resulting therefrom. The experimenter had gone still further and made such bars so short that neither of the fundamental notes are within the limits of audition, but the resulting beat-tone can be heard quite distinctly. In all cases the frequency of the beats agree with that calculated from Dr. Kœnig's formula, and secondary beats follow the same law.

The phenomenon of beats was further illustrated by an experiment remarkable for its simplicity. A tuning fork held in the hand was moved towards a wall or other reflecting surface at various velocities. According to Doppler's principle, as the fork recedes from the observer and approaches the wall, the frequency of the direct waves is less, and that of the reflected waves greater, than that of the fork, and these two series of waves produced beats. Coming to the second half of Dr. Kœnig's researches, Dr. Thompson said that Helmholtz contended that the "timbre" of musical sounds was not affected by differences of phase amongst the component tones; on this point, however, Kœnig had come to the opposite conclusion. The subject was treated experimentally by means of a wave siren, consisting of a brass disc whose edge had been cut like a coarse-pitch circular saw, each tooth being shaped to a calculated wave-curve. Against this a stream of air issuing from a slit could be directed. By inclining the slit to one side of the radius or the other, the phases of the component waves could be altered, and this had a marked effect on the character of the sound produced.

After a large number of experiments of great scientific interest, Dr. Kœnig acknowledged the very cordial reception accorded to him by the meeting. At the close of a short discussion, in which Lord Rayleigh, Mr. Bosanquet, and Mr. Blakesley took part, the President said that, in view of the production of audible sounds by the beats from notes beyond the range of audition, it might be possible to demonstrate that insects produce sounds inaudible to the human ear by putting several together in a box and listening for beat tones.

Notes.

ENGINEERING PHOTOGRAPHY.

A process has been brought out by Messrs. J. Halden & Co., 8, Albert Square, Manchester, whereby, instead of engineering tracings being copied by the usual blue print process, it is possible to reproduce them in black lines on white paper. This is a decided advantage, and some specimens we have seen are clear and distinct. A dark room is not necessary.

THE ADVANTAGES OF EXHIBITIONS.

Some firms are found to be constantly represented at Exhibitions, while others are indisposed to take the trouble and expense which accompany them. If a show is made at all, it is advisable to do the thing well, or else the money is thrown away. Although at the late Barcelona Exhibition English exhibitors were not numerous, those who put in an appearance seem to have reaped a benefit, for the British Consul at Barcelona states that one of the results of the Exhibition has been to increase the importation of English machinery. Several instances have occurred of Catalan manufacturers who, having been struck with the excellence of the spinning and weaving machinery, have since proceeded to England in order to arrange for the purchase and erection in their own factories of similar machinery. All manufacturers are alive to the necessity of having modern machinery, and large sums have been spent on new looms of French, Belgium, and English make.

PAPER MILLS IN CHINA.

Not only are the Chinese developing their mines and railways, and such important industries as those connected with cotton in all its departments, but they are also pushing on many of what may be called the subsidiary industries. The Japanese have established a very large number of paper mills in their country, and now the Chinese are following their example. A company has been formed in Canton, composed entirely of Chinese, under the title of the Canton Paper Manufacturing Company, and they have erected an establishment costing about £30,000, and it is estimated that this will turn out about forty tons of paper per week. At first it is intended to produce only the varieties of brown paper in common use in China, but the plant can, without much difficulty, also be adapted to the manufacture of white paper, if necessary. All the employés will be natives, except the manager and engineer, who are British. Several of the Chinese who are engaged in the works have had experience in American paper mills for some years.

MINING IN CHILI.

Some time ago Consul Grierson, of Coquimbo, stated that attempts were being made at Andacolla to obtain alluvial gold, but these did not succeed. He attributes this fact, not to the scarcity of gold, but to the want of proper machinery. Several rich mines exist near Ovalle. Owing to the uncertainty of the copper industry, more attention has been paid to silver mining, and some good finds have been made in the Condoriaco, Quitana, and Arqueros districts, though on the whole expectations have been disappointed. The demand for manganese ore fell off last year, and, in consequence, shipments were small, but this year's prospects are better. The Chilian Manganese Company, Limited, are laying a narrow gauge line of railway between their mines and the port of Carrizal, a distance of about twenty miles. It is expected that mining interests will be advanced by the Government taking over several lines of railway in the Coquimbo district.

THE VAN RYSSELBERGHE SYSTEM.

We have recently received a book containing diagrams and statistics of the Van Rysselberghe system of working telegraphs and telephones simultaneously on the same line, but we cannot discover any new improvements which are likely to extend the use of this method. The total length of lines on which this system is stated to be in use is given as 15,747 kilometres; but in November, 1887, 15,123 kilometres were at work, so that since then there has only been an increase of about four per cent. The system in its simplest form consists of the introduction of impedance coils into a telegraph circuit, for the purpose of wire-drawing the currents, and rounding them off so that they give a continuous motion to the diaphragm of a telephone, instead of a sharp click at the commencement and make and break of the telegraph key. But to make the method of any practical use, condensers of considerable capacity and resistances have to be employed, a system which renders it impossible to work the telegraph instruments at any high speed, and offers difficulties also to the telephone service. These difficulties, such as the impossibility of "ringing up" in the ordinary way, necessitate the invention of special call apparatus, and in this way a "system," so dear to the Frenchman and to the American, is built up. For mere Morse lines, the retardation is not very serious, but Hughes' instruments, so largely used on the Continent, can hardly be worked on this method, while anything like a Wheatstone instrument would be rendered useless. The Van Rysselberghe system was given a two years' trial on the Government lines in Holland, and had to be abandoned, and a similar fate met it in several other countries. We are not aware that it has ever been tried in this country, where, bad as many of the telephone exchange systems are, they at all events have separate wires. The telegraphic methods in use on the 15,717 kilometres to which we have referred are evidently of a very elementary kind.

THE GOLD FIELDS OF WESTERN AUSTRALIA.

Glowing accounts come to hand respecting the prospects of the gold fields in this Colony. A report from the Pilbarra country states that two men who were starting for the Nullagine had gone but a few hundred yards when their horse kicked up a small nugget. They looked about and found more gold, and in nine days obtained 26oz. It is also stated that a man found in the conglomerate in the main camp at Pilbarra a stratum of gold-bearing ore about 4in. thick at a depth of 15ft. to 20ft. It gets thinner but richer as it is worked, and it takes an average of eight days to obtain a load. It is estimated that he has got nearly 1,000oz. in two months. Another big nugget, weighing 30oz., has been found near Mosquito Creek, and also one weighing 20oz.

AGRICULTURE IN QUEENSLAND.

A return has recently been issued by the Lands Department at Brisbane, showing the applications made for agricultural and grazing farms, under the Crown Lands Act of 1884, for the year 1889. The returns are comprehensive, and are interesting as showing the advantage which has been taken of the 1884 Act as compared with its predecessors, and the revenue which it has created. Throughout the whole Colony, the number of agricultural farms applied for was 1,644, with an area of 322,731 acres. The rent paid on them was £5,818 8s. 5d., of which £127 17s. 4d. was received in the form of land orders. The survey fees amounted to £7,428 10s. 3d. The grazing areas applied for numbered 210, with an area of 1,363,293 acres, producing a rental of £8,194 8s. 1d., while the survey fees on these amounted to £5,436 6s. Taking the two lots together, there were, therefore, 1,854 farms applied for during the year, the total area being 1,686,024 acres, and the total rent received in cash and land orders £14,012 16s. 6d. For 1888 the returns were—1,766 farms; area, 1,683,207 acres; rent, £12,735. The increase for the year just past is therefore little more than perceptible.

AGRICULTURAL MACHINERY IN RUSSIA.

In 1888, owing to the good harvest, there was a large sale of agricultural machinery in the Taganrog and Rostov district. Last year the numbers sold were only about half as much, but that business was considered satisfactory. About 6,000 ploughs were sold, most of them being German. Consul Talbot states that neither English nor American ploughs can compete with them in price. A good many Russian engineers have now taken up this branch of manufacture, and are underselling even the Germans, but their products are not as good. About 1,000 reapers, 500 mowers, 500 hay rakes, 200 horse-gear thrashers, and 55 steam thrashers were sold. The steam thrashers were all English, but the reapers, mowers, and rakes were American. Efforts are being made by many of the leading agriculturists in South Russia to obtain a diminution of the duties on agricultural machinery. Local machine shops did a good trade last year. From Berdiansk Vice-Consul Lowe reports that heavy sales were made of the home-made reaping machine, which cuts very low. The foreign reaper was found almost useless last year, not being able to cut low enough for the excessively short growth of straw. A very large business is done every year in the Russian reapers, makers being unable to meet the demand.

Patent Record.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

12th May, 1890.

7334. Phillips & Archer ..... Valve and piston rods.
7337. Cocker, B. F. ..... Starting and stopping tramcars.
7338. Leach & Wilkinson..... Forging shafts.
7340. Keep, F. ..... Strainers for wire fencing (*Morrin*).
7348. Bennett & Hides ..... Metallic rods, tubes, &c.
7349. Alley, S ..... Nut locks.
7350. Martin, P. A..... Nail-making machinery.
7358. Greening, W. A. ..... Packing rings of pistons.
7359. Westwood, F. ..... Lubricators.
7361. Martin, E. ..... Filtering machinery.
7363. Gebelein, L. ..... Machine for polishing slate.
7366. Webb, S. H..... Driving wheels
7368. Flower, Flower, & Cousins ..... Scrubbing machines.
7369. Kiddier, H..... Straight bar knitting machines.
7371. Wood, C..... Railway chair.
7372. Brokas & Irving ..... Lubricating bearings.
7374. Nobbs, J. J..... Shields for tunnelling.
7375. Saint, T. ..... Governors.
7377. Imray, O..... Rolls for rolling hay forks (*Spiegel*).
7381. Wells, C..... Steam engines.
7385. Livens, F. H. ..... Thrashing machines.
7386. Boult, A. J. ..... Spring motors (*Richard*).
7388. Thompson, W. P. ..... Injectors (*Schutte*).
7389-90. Longmore & Watson Decorticating machines.
7391. Thompson, W. P. ..... Injectors (*Schutte*).

13th May, 1890.

7395. Ligowsky, G..... Lathe tools.
7397. Pain, A. C..... Lubricating steam engines.
7403. Johnson, J. Y. ..... Type-setting machines (*Chadwick*).
7406. West, W..... Apparatus for pressing bricks.
7407. Huntington, F. A. ..... Crushing mills.
7412. Outram, E..... Steam gauges.
7419. Walkington, W. ..... Town refuse destructor.
7424. Ligowsky, G..... Screw cutting dies.
7426. Lake, H. H..... Vacuum pumps (*John Patten Manufacturing Company*).
7427. Knickerbocker, R. ..... Brick-making machines.
7429. Ligowsky, G..... Grinding machines.
7431. Rothwell, R. P. ..... Sinking shafts.
7432. Garfield, L. M. ..... Railway switches. (17th October, 1889.)
7437. Campion, W. ..... Sewing machinery.
7440. Boult, A. J. ..... Railway ties (*Wallace*).
7442. Greenbough, J..... Rotary engines.
7447. Lake, H. H..... Printing presses (*Cottrell*).
7449. Watkins, T. ..... Railway trucks.
7451. Braby, J..... Windlasses.
7454. Bunnell, M. G..... Road-making machines.
7455. Goodson, G. A. ..... Justifying machines.
7457. Stewart, R. ..... Portable buildings.
7458. Landis, J. H. ..... Band saw machine.
7459. Schoff, F. ..... Casing for flexible shafts.
7460. Stevens, R. ..... Fencing.
7461. Lake, H. H..... Annealing metals (*Russel and Erwin Manufacturing Company*).

14th May, 1890.

7470. Baird, R. ..... Stuffing boxes.
7472. Sugden & Hardaker ... Jacquard machines.
7475. Edwards, W. J..... Grading and ditching machines.
7477. Mathus, H..... Ironing machines.
7483. Smith, Sen., Smith, Jun., & Smith ..... Machines for straightening steel plates.
7500. Hesse, L. ..... Destructors for town refuse.
7502. Munzenmaier, C. G..... Tube cleaners.
7504. Boult, A. J. ..... Embroidery machines (*Legrand*).
7508. Thompson, W. P. ..... Rotary pumps (*Bornet*).
7514. Ambler, W..... Moulding metal.
7517. Coxon, J. N. ..... Gearing for rotary motion.
7519. Renaud, R. M. L. G..... Liquid meters (*Lacoste*).
7524. Druckenbrodt, W. ..... Apparatus for measuring strains or forces.
7528-9. Lock, C. ..... Locomotives.
7530. Brodin, G. A ..... Lathes.
7538. Piatkowski, J. J. ..... Hoisting apparatus.
7539. Hornsby, Innocent, & Smith ..... Reaping machines.
7541. Bayly, J. P. ..... Locomotive head lights (*Crowley*).
7544. Bayly, J. P. ..... Drawing, compressing, and polishing metal bars (*Moltrop*)
7545. Bayly, J. P. ..... Thread doubling machine (*Perkins*).

15th May, 1890.

7550. Fairburn, J. ..... Looms.
7554. Duvinage, G..... Slide valves.
7574. McDougald, A..... Car couplings.
7587. Hunt, T. ..... Planing and milling machines.
7588. Goss & Goss..... Reaping machines.
7590. Sanderson, F. ..... Typewriting machines.
7591. Haddan, R..... Automatic balances for grain (*Riedinger*).
7592. Franke, C. ..... Rock drills.
7594. Ford, B. F. ..... Looms. (26th October, 1889.)
7595. Walters, W. M. ..... Ballast tanks for steamers.
7598. Richardson, C. J..... Paper-making machines.
7600. Boult, A. J. ..... Hydraulic engines (*Kölz*).
7603. Capel & Ladd ..... Baling presses.
7606. Hemans, W. B. ..... Mounting naval guns (*De Latouche*).
7607. Martin, A..... Explosive projectiles.

16th May, 1890.

7612. Barraclough & Rhodes Tool holders for lathes.
7615. Coultard & Hargrave Securing rails in chairs.
7620. Fletcher & Clare ..... Gas ovens.
7623. Chapman, G. ..... Propulsion of vessels.
7625. Grimshaw, W. D. ..... Consumption of smoke.
7626. Johnson, J. Y. ..... Engines (*Loutsky*).
7627. Crossley, S. ..... Scutchers.
7628. Groombridge & South Brakes for tramcars.
7630. Morison, W. C. ..... Propellers.
7631. Towler, J. A. ..... Compound engines.
7632. Wolseley & Craven ... Shafts.
7635. Willoughby & Horsfield ..... Pulleys, &c.
7639. Young, Young, & Wright Hydraulic pumping machinery.
7640. Baynes, Topping, & Whittaker ..... Looms.
7642. Surridge, A. ..... Blowing engines.
7643. Bury & Booth ..... Looms.
7649. Brown, T. A..... Railway chair.
7652. Swalwell, J. ..... Machinery for the manufacture of horseshoe nails.
7659. Rutter, G. E..... Weighing machines.
7667. Kingsford, C. ..... Pressure pumps.
7671. Little, H. W. ..... Steam engines (*Little*).
7680. Heidelmann, W. ..... Printing apparatus.

17th May, 1890.

7682. Rutter, G. E..... Weighing machines.
7683. Grindrod, J. K. ..... Windmills.
7688. Martin & Goodey..... Propelling ships.

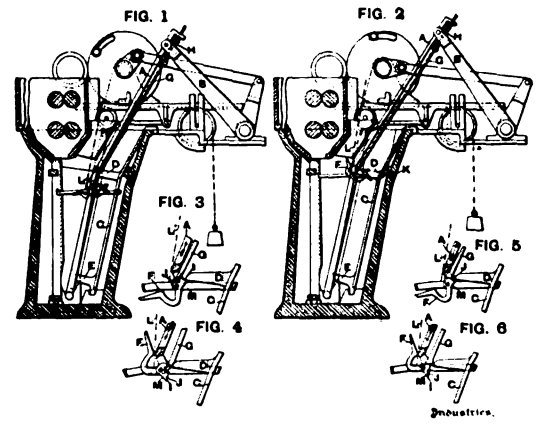
ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

Delivering Coal to Waggons, &c.—*M. Nichols, Leeds.*—The inventor's object is to provide means for delivering coal from screens on a pit bank into railway waggons in such a manner as to minimise the breakage of the coal. The invention comprises a helical shoot which intercepts the coal in its fall from the screen to the waggon. The figures are respectively a front and side elevation of the appliance. The following is the mode of operating the appliance: When the empty coal waggon has been brought under the casing A the pawl B is moved out of gear with the wheel C, which is then rotated by means of the hand-wheel D. This motion uncoils the rope E from the barrel F, and allows the spiral shoot G and its attachments to descend until the lower edge of the spiral shoot is slightly above the

FIG. 2. FIG. 3.



bottom of the coal waggon. The pawl B is then thrown into gear, and holds the spiral shoot in this new position. The coals are now allowed to slide down the inclined side spout on to the upper end of the spiral shoot G, down which they slide to the bottom of the waggon. The coal is moved sideways from the bottom of the shoot by the attendant or "dresser" in the waggon. When this end of the waggon has been filled round, up to the level of the bottom edge of the spiral shoot, the shoot G is raised a suitable height by means of the hand-wheel D and the mechanism described. The supporting rod I has the same pitch as the spiral shoot G, and passes through a fixed nut J; therefore the raising of the spiral shoot G and the rod I imparts a corresponding rotation to the shoot G. In consequence of this rotation the outer end of the spiral shoot retains throughout this motion the same relative position to the edge of the side spout, so that a vertical section of the spiral shoot in proximity and through the centre line of the side spout remains the same, whatever may be the position to which the spiral shoot has been raised or lowered. Four claims are made.—No. 7917. May 18th, 1889. 8*d.*

Tanks for Storing Petroleum.—*J. Stewart, T. Charlton, & J. Casey, London.*—For storing and transporting volatile and inflammable liquids tanks and other vessels have been constructed so that the increase or reduction of bulk of the liquids is compensated for by means of non-inflammable gases or water contained in suitable chambers. When water is so used some of the volatile liquid becomes absorbed or mixed with it, and the water being afterwards discharged the absorbed liquid is lost. To recover this liquid from the water the inventors construct an additional receiver or accumulator connected to the tanks containing the oil or liquid stored under pressure of water. The accumulator receives the surcharged or waste water as it is drawn off from the tank. The water is caused to pass outwards through a series of filtering mediums or apparatus, of any form, to separate the oil from the water as it is allowed to run away to waste. Claims: (1) In combination with safety vessels or reservoirs for storing petroleum and other inflammable liquids, the application and use of filtering apparatus for the purpose described; (2) the improvements connected with tanks used for the storage of petroleum and other inflammable liquids, as described.—No. 9986. June 18th, 1889. 6*d.*

Coating Metal Sheets with Tin, &c.—*H. F. Taylor, Tynant, Neath.*—These improvements refer to the cradle and nipping apparatus for taking down the plate to be coated, canting it and raising it into the nip of the rolls on the exit side of the pot. The appliance is illustrated applied to a self-acting gear such as described in a previous specification No. 4350 of 1888. Fig. 1 is a vertical cross-section through a tinning pot with the self-acting gear. In connection with the rod A and lever B is a tappet bar C (shown in detail, Figs. 3 and 4). The upper end of C is fixed to the pot. Its tappets or steps D E act upon the two faces set at an angle on the upper hook F. The plate is nipped between the hook F and cradle rod A. To retain the nipper hook in the open or closed position, the upper end of a rod G is held in a yielding manner by a spring H in a projection from the cradle rod A. When the cradle rod A is nearly in its uppermost position and whilst still rising (see Figs. 1 and 2), the upper face

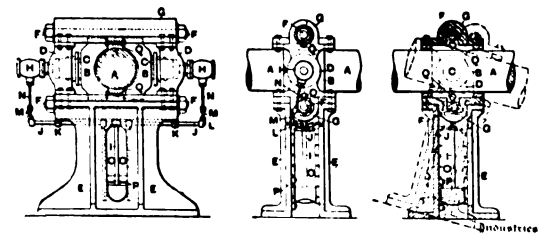


FIG. 1 FIG. 2

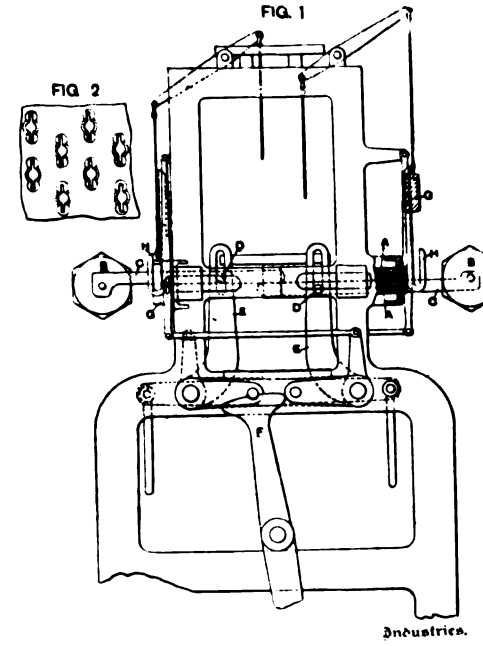
I of tumbler having recess J comes against the upper tappet D, the latter thus depressing that end of the hook F, and raising the opposite or nipping part so as to nip the inserted plate L ready subsequently to take it down as required into the coating material. The cradle is then lowered. When the cradle with the plate is nearly in its lowest position, the nipper hook F or tumbler comes with its face M against the lowest tappet E, and the nippers are opened again so that the plate is released, and can be canted, and in the rising stroke entered into the nip of the rolls on the exit side of the pot. Claims: (1) In apparatus for coating plates with tin, lead, or other metals or alloys, a plate-nipping hook F provided with faces which is carried up and down by machinery or by hand, said faces being adapted to come against tappets for the purpose of opening and closing the hook, which is retained in the closed or open position by a yielding part in connection with a spring or weight above the coating metal, substantially as set forth; (2) the application of a rod which is operated by a spring or weight above the coating metal and which serves to hold the nipper hook in the required closed or open position, substantially as set forth; (3) the nipper hook F which is carried up and down by rod A from a reciprocating lever B and has faces which are adapted to come against the stationary tappets D and E, said hook being retained in the required closed or open position by the elastically mounted rod G, substantially as described with reference to the accompanying illustration.—No. 6594. April 17th, 1889. 11*d.*

Preventing the "Racing" of Propellers.—*F. G. Harvey, Vere, Jamaica.*—The invention consists essentially in arranging a brake, operated by hydraulic or other fluid pressure, in conjunction with the propeller shaft, and in utilising the motion of the vessel for controlling the valves by means of which the supply of fluid for operating the brakes is regulated. In the accompanying illustrations, Fig. 1 is a side elevation of apparatus constructed according to the invention, Fig. 2 is an end view of the same, and Fig. 3 is a vertical section on the line X X of Fig. 1. A is the propeller shaft, and B B are two brake-blocks which are adapted to grip it; the said blocks being provided with plungers C C entering cylinders D D supported on the frame E. F F are tie-rods, which pass through lugs G G on the cylinders D D, for preventing the said cylinders from moving relatively to each other. H H are valves for controlliug the supply of the fluid to the cylinders D D. I is a weighted arm or lever which is suspended from the shaft J carried in bearings K K on the frame E. At each end of the shaft J is a lever-arm L connected by a link M to the stem N of one of the valves H H, in such a manner, that when the shaft J is rotated by the weight the valves are operated. The weighted arm I is suspended between

FIG. 1. FIG. 2. FIG. 3.



guide-plates O O, so that it is not affected by any rolling motion of the vessel, and so that it will only operate the valves when the stern of the vessel rises out of the water. When the bow of the vessel is higher than the stern the weight on the said arm is supported against one side of the frame E, a cushion P being arranged to prevent the weight from forcibly striking the said frame during the lurching of the vessel. Claims: (1) Braking the shaft of the propeller of a steamship to compensate for the non-resistance of the water, and utilising the motion of the vessel for controlling the application of the brake-power, substantially as and for the purpose described; (2) in apparatus for utilising the motion of a vessel for applying a brake to the propeller shaft, the combination of brake-blocks adapted to be forced into contact with the said shaft by fluid pressure, valves for controlling the supply of fluid for actuating such brakes, and a shaft carrying a weighted arm, the said shaft being connected with the stems of the valves, all substantially as described; (3) the improved apparatus hereinbefore described and illustrated in the accompanying drawing for preventing the "racing" of the propellers of steamships.—No. 10097. June 20th, 1889. 6*d.*

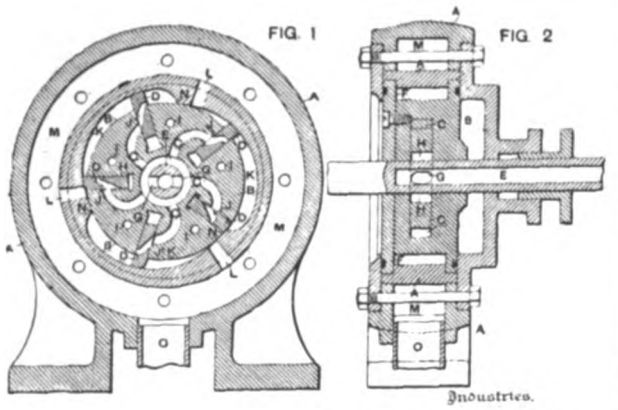
Coupling Railway Carriages.—*G. W. Moon, London.*—For the purpose of facilitating the coupling and uncoupling of railway and other carriages without the necessity of men having to go between them, the inventor attaches to the existing hook at the end of the draw-bar, another hook which has a hinged joint and moves in an oblique direction slightly out of the horizontal. This hook engages in a similar hook upon the opposite carriage. When the carriages meet the hooks displace one another and move upon their hinged joints, but on passing their hooked ends they return to their normal positions by force of gravity consequent upon the sloop of the hinge, and become interlocked. Chains are secured to the hinged hooks to enable them to be pulled back and disengaged from the side of the car. Claims: (1) In apparatus for automatically coupling railway or other vehicles, hinging or pivoting the arm carrying the coupling hook at an angle of 60° to the horizontal or vertical or approximately; (2) the construction of automatic coupling apparatus for railway or other vehicles as described.—No. 6983. April 26th, 1889. 6*d.*

Looms.—*H. Fawcett, Kidderminster.*—According to this invention the loom has two or more jacquards each, with its own cards. Each jacquard is tied up with the figured warps of the fabric, and when at work raises them in selected order under control of the cards. Only one jacquard is at work at a time, mechanism being provided for putting them in and out of work. In weaving bordered carpets with a loom constructed according to this invention, the change from border to pattern, and *vice versâ*, is made by stopping one jacquard and starting another. In Fig. 1 of the accompanying illustrations an elevation of the jacquard mechanism is shown. A are the jacquard needles, B the jacquard cylinders, each carrying its own cards. The cylinders are supported in sliding bars C, which have inserted in them pins D. These pins work in the slots of the bell-cranked levers E, so that as the levers E are oscillated by the cam lever F the sliding bars C, and with them the jacquard cylinders, are moved to or away from the needles, one cylinder approaching as the other recedes. The cylinder which is to be kept out of action is removed the farthest from the needles. In addition to providing two jacquard cylinders, two levelling boards G are

FIG. 1

FIG. 2

also provided. Either of these is brought into action by lowering it into the hooked ends of a swinging arm H. The levelling boards may be connected to the shafts of the lever E as shown, so that their movement operates both cylinders and boards. The several holes in the lifting board H, up through which the lifting cords are led, are shaped in the manner shown at Fig. 2, with a slot extending from opposite sides of the hole. When the cords pass centrally through the hole and the board is lifted in the ordinary manner, the knots on the cords will pass freely through the holes, and the cords will not be raised; if, however, the needle to which any cord is threaded is pushed from its central position either towards one end or the other, the cord will be deflected and moved into either one or the other of the narrow slots which extend from opposite sides of the hole, and then when the board is lifted the cord is carried up with it, the knot not being able to pass through the slot. Claims: (1) The manufacture of bordered carpets in looms provided with two jacquard cylinders, one carrying cards suitable for controlling the making of the border, the other carrying cards suitable for controlling the making of the body, and with either jacquard cylinder capable of being brought into action whenever desired; (2) a loom having two jacquard cylinders, either of which can at pleasure be brought into action when the other is held at rest, each cylinder carrying its own set of cards, and when in action controlling the raising and lowering of the warp; (3) the construction of jacquard mechanism for looms substantially as described and illustrated.—No. 8261. May 17th, 1889. 8*d.*

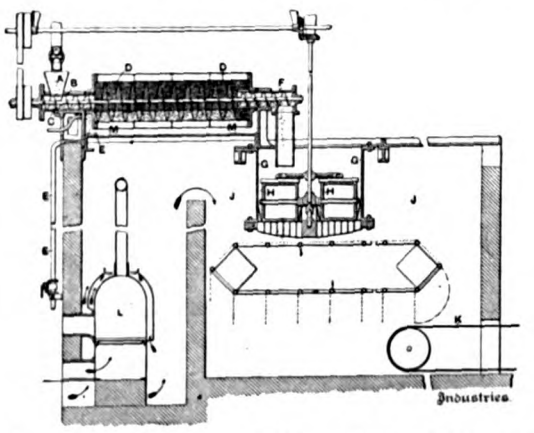


Fog Signalling Apparatus.—*W. Smith & G. Stephenson, New Wortley, Yorkshire.*—Along the side of the railway tract are fixed at right angles to it a number of rollers. The rollers are connected to a switch so that their positions may be altered by the signalman. On the locomotive there is pivoted a lever, whose upper end is arranged to strike the hammer of a bell when the lower end is raised. The lower end of the lever is raised by the rollers when they are placed in a certain position by the signalman, and as the locomotive travels pass them. The number of rollers correspond to the number of blows to be struck on the bell. When no signal is to be made the rollers are shifted in

Digitized by Google

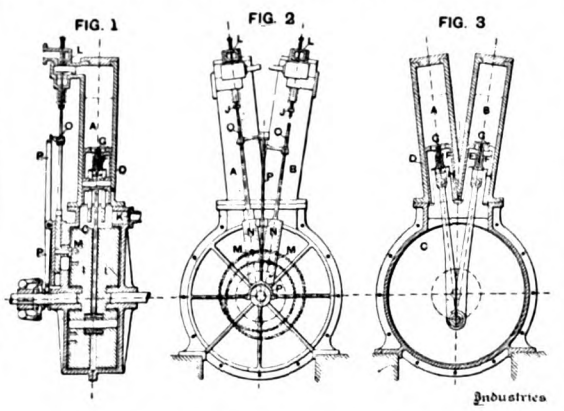
their position by the switch and the lever passes by without being raised. Claim: The arrangement, construction, and combination of parts forming the fog signalling apparatus.—No. 8781. May 27th, 1889. 6*d*.

COMBING MACHINES.—*J. C. Walker & J. E. Stephenson, Leeds.*—The improvements refer to Noble's and other kindred combing machines. Firstly, in order to cause the large and small comb circles to rotate with greater steadiness, runners are provided underneath the rack circles, having their peripheries running in a diagonal line to the plane of the movement of the rack circles. These runners may be fixed to the rack circle plate and rotate with it, or they may be placed on any suitable part of the steam chest or framework of the machine, working against a suitable annular ring, such ring being formed on the rack circle; or the angular runners may be mounted upon the rack circle and travel round with it. Secondly, the circular steam chest for imparting heat to the circular combs is made of a trough-like form, and a thin plate used to cover the top, the cover being riveted, soldered, or otherwise secured to the top. By this arrangement a steam chest is provided of larger steam capacity, the heat is given off readier at the part required, and the construction is simplified. Claims: (1) The arrangement of pulleys or runners and angular rings or parts upon which the runners or pulleys revolve, such pulleys or runners and angular rings or parts having their peripheries or steadying surfaces in a diagonal line to the plane of movement of the rack circle, whereby greater steadiness is imparted to such rack circle when in motion, as described; (2) the construction of steam chest, having a thin plate or cover fixed on the top, as described.—No. 13755. August 31st, 1889. 6*d*.



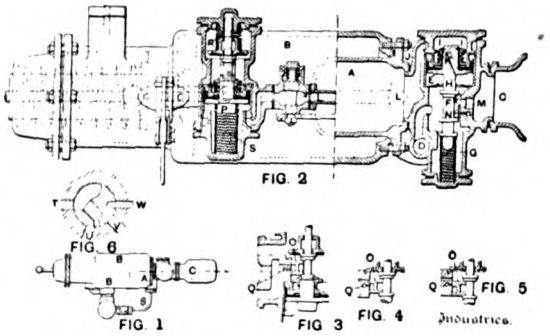
ROTARY ENGINES.—*H. Bleasdale, Astley Bridge, Bolton.*—This rotary engine consists of a cylindrical chamber A, which is stationary, and of a disc B, which is made to revolve about its axis in bearings in the former. The disc B is mounted on the steam pipe or hollow shaft E, with the openings G to convey steam into the chamber or cavity H in the disc B. The latter is also provided with the passages C leading from the chamber or cavity H to the slide valves D. The disc B is fitted with the loose plate or disc F, secured by set screws to facilitate the mounting of the disc in the casing or framing A. The slide valves are constructed with the ports J. The inside of the casing or framing A is constructed with the eccentric or cam-like working surfaces K to operate the slide valves D in their respective slots as the disc B rotates in a direction from right to left. The

casing or framing A is provided with the exhaust ports L leading into the exhaust chamber M between the inner and outer shell of the casing A. This engine operates in the following manner:—Steam is conveyed from the boiler into the hollow shaft E, from whence it passes through the openings G into the chamber or cavity H and passages C to the slide valves D. As the disc B rotates, the outer ends of the valves are pressed tightly against the eccentric or cam-like working surfaces K by the action of steam. When the valves pass the points N, they are at once blown outwardly by the pressure of steam. As the disc B rotates, the valves are moved inwardly by their movement or traverse on the eccentric or cam-like working surfaces K. When the steam side of the slide valves pass the exhaust ports L, the steam in the spaces between the points N and the exhaust ports L passes into the chamber M and away through the pipe O into the atmosphere, or to any suitable condensing apparatus. Claims: (1) In a rotary steam engine the use of the casing or framing A, with the eccentric or cam-like working surfaces K for the purpose of operating the valves so as to work steam expansively, substantially as described and as shown on the drawings; (2) in a rotary steam engine the use of the slide valves provided with the steam port J, substantially as described and shown for the purpose specified; (3) in a rotary steam engine the combination of the disc B, hollow shaft E with the openings G, chamber or cavity H, passages I, slide valves with the ports J sliding to and fro in the slots C, the casing or framing A with the eccentric or cam-like working surfaces K and the exhaust ports L, the casing N, and the side discs, applied and operating substantially as described and as shown on the drawings; (4) the general construction, combination, and arrangement of parts forming the improved expansive rotary steam engine, substantially as described and as shown on the drawings.—No. 9615. June 11th, 1889. 8*d*.



REVERSING MECHANISM FOR ENGINES.—*F. Daugy, Paris.*—The mechanism consists essentially in an arrangement by which the eccentrics may be turned through an angle of 180° on the crank-shaft. The eccentrics are formed in one with a loose sleeve upon the engine-shaft, this sleeve being carried round with the shaft by a projection upon the latter. The projection abuts against one or the other of two shoulders in a circular groove in the sleeve, and the shoulders are so arranged that the shaft can turn half round relatively to the sleeve in moving its projection from one shoulder to the other. If during the running of the engine in one direction the eccentric sleeve be turned half round upon the crank-shaft, it will be evident that the slide valves will be worked in the contrary direction to that in which they previously worked, and that consequently the motion of the engine will be reversed. The reversal of the position of the eccentric sleeve is effected at will by the engine itself by means of an auxiliary shaft parallel to the crank-shaft, and capable of being put in gear with it at one end at the required moment. The other end of the auxiliary shaft carries a pulley which gears frictionally with a circular surface upon the eccentric sleeve. When the auxiliary shaft is put into gear with the crank-shaft, the former is driven in the reverse direction to the latter, so that the friction pulley reverses the eccentric sleeve, and thus the engine. Three claims are made.—No. 10,100. June 20th, 1889. 8*d*.

PREPARATION OF CEREALS FOR BREWING.—*A. Perry, London.*—The object is to render rice and other grain more suitable for brewing, distilling, vinegar making, and for purposes of food. For this purpose the grain is first submitted to the action of hot water to cook the grain and saccharify the starchy constituents.



It is then shredded in a suitable machine, and the shreds removed and dried. The apparatus used in the above processes is shown in the illustration. The rice or other grain is fed to the hopper and falls into the cylinder B, where it is propelled by the helical blade C to the gauze cylinder D. The gauze cylinder has secured in it a helical gauze blade, and revolves about its axis partly immersed in boiling water. The water is heated by steam supplied through pipe E. As the cylinder D revolves, the rice is conveyed by its helical blade along the cylinder until it is finally discharged into the cylinder F, from which it passes to the shredding machine. During its travel through the gauze cylinder the rice is partly cooked by the boiling water. The shredding machine is composed of a cylindrical vessel G with a perforated bottom. In the vessel are heavy rollers H, which are revolved and roll over the surface of the perforated bottom. The rice, therefore, as it falls into the vessel is forced through the perforations, and issues in a thread-like shape. These shreds, as they fall from the shredding machine, are received upon the travelling belt I, which conducts them through a heated chamber J to dry them. The dried shreds are finally removed from the chamber by a second belt K. The chamber is heated by a furnace L, which can also be made to heat the boiler supplying steam to the trough M. Twelve claims are made.—No. 221. January 5th, 1889. 8*d*.

GAS ENGINES.—*G. Daimler, Canstatt, Germany.*—This invention relates to a modified construction of engines of a type described in a previous specification, No. 4315 of 1885. Two working cylinders are connected to and communicate with one and the same closed space containing the crank-shaft. The rods of both pistons are so connected to the crank-shaft that they perform their strokes together, both acting as pumps for compressing a charge of air or of gaseous mixture in the said closed space, but the admission of the combustible charges into the cylinders being so regulated that while the one piston is performing its working

forward stroke the other is performing its suction or charging forward stroke. The illustrations show one form of this improved engine. C is a closed chamber communicating with the two cylinders A B, and constituting with the pistons of the latter a pump to supply the outer ends of the cylinders with air or gaseous mixture. The charge of air or gaseous mixture is drawn in at the opening K during the up-stroke of the pistons, and is compressed, and at the end of the down-stroke passed to the cylinders through valves G fitted in the pistons. The valves G are pressed downwards by springs F, whose force is removed at the end of the down-stroke by the supporting sheave coming into contact with the fixed forks H. L is the entrance for the main explosive charge, and J the exhaust valve. The valve J is operated by a system of tappets worked by sliding blocks M. The blocks M impart an up and down motion to the rods N, and cause the bell-cranked levers O to strike against the valve rods and lift the valves, unless the levers O are thrown out of the vertical by the action of the governor lever P. The charge of each cylinder is conducted in three stages. The piston at the end of its working down-stroke opens the exhaust and propels the exploded charge by admitting a preliminary charge of air or gaseous mixture from the chamber C through the valve G, the air or gaseous mixture having been previously compressed by the down-stroke of the pistons. The pistons next make their up-stroke, and draw in a fresh supply of air at K, whilst the valve J closes. A second and the main charge is now taken in through the valve L as the piston descends, and at the end of its stroke a third charge is taken in from the chamber C, bringing the whole charge up to the pressure in C. The whole charge is finally compressed at the next up-stroke, and then exploded. The force of the working charge keeps the valve G closed after the pressure of its spring is removed and until the exhaust valve is opened. The cylinders are arranged so that one takes in its main charge as the working stroke is made in the other. Two claims are made.—No. 10007. June 18th, 1889. 8*d*.

PNEUMATIC BRAKES.—*A. Wenger, Paris.*—These improvements are to accelerate the action of pneumatic railway brakes and improve the construction of the engineer's brake valve. To accelerate the action of the brake, an apparatus as illustrated in Figs. 1 and 2 is provided. Fig. 1 is a plan and Fig 2 an enlarged elevation. A, B, and C are reservoirs. The reservoir B is always in communication with the brake cylinder, and therefore the brake piston is subjected to the variations of pressure in it. The train pipe D communicates with the chamber E of a slide valve F. The valve F covers the ports of the reservoir C, and has imparted to it an up-and-down motion by the spring G working in conjunction with the piston H. The air from the brake pipe D normally passes the cap leather of the piston H, and escapes through vents I and port J to the reservoir A, and from A by the pipe L to the reservoir B for the brake cylinder. This part of the invention acts as follows:—When the pressure in the train pipe D is reduced the force of the air above the piston H overcomes the spring G and shifts down the valve F. The port M is then opened, and the air in the train pipe and from the reservoir A escapes to the reservoir C until the pressure upon the top and bottom of the piston H is equalised. The spring G then recovers itself, and lifts the valve F up until it covers the port M, and puts it in communication with a second port N, open to the atmosphere. The reservoir C is thus emptied, ready to repeat the operation described. To make the pressure acting in the brake cylinder correspond with the reduction of pressure in the train pipe a valve of the following construction is interposed between the reservoirs A and B. This valve O (Figs. 3 and 5) is raised and lowered in a somewhat similar manner to that already described. It is actuated by a piston P, whose under side communicates with the pipe L leading from A to B. In the figures the piston and valve are shown

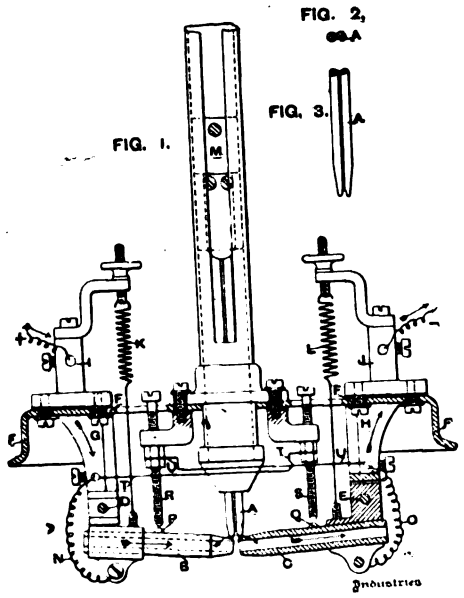
in their raised positions, the pressure of air at the top and bottom of the piston being in equilibrium, whilst the brake cylinder is in communication with the atmosphere through the port Q. On reducing the pressure in the train pipe D, and consequently the pipe M, as already explained, air from B forces the piston and valve O down, so that air now passes from B to the brake cylinder X, bringing the brakes into play. As the piston P descends, however, it is released of the pressure due to the spring R (see Fig. 5), and the piston reascends until it receives the load of the spring R (see Fig. 4), and the force of that and the pressure in B equilibrates the force of S and the reduced pressure in L. The force upon the brakes is thus maintained until the full pressure is again brought to bear and the valve O forced up. The driver's brake-cock is shown in Fig. 6. The casing has four passages—T opening under the plug and supplying compressed air, U opening to the air, V leading to the discharge reservoir, W leading to the train pipe. Four claims are made.—No. 9480. June 7th, 1889. 8*d*.

SAWING MACHINERY.—*S. Bastow, Leeds.*—This specification describes an improved self-acting feed, which may be used either for ordinary ripping, deep cutting, cutting at any angle, and to feed a number of boards through at one time. The feed rollers, four in number, are mounted in pairs in two frames. These frames carry the feed rollers at right angles to a bed, along which they are slidden by a right and left hand screwed shaft. The bed reaches across the saw frame at right angles to the saw, and is pivoted at its centre upon a longitudinal and horizontal shaft, whose bearings are fitted in quadrant guides. For ordinary deep cutting the bed is horizontal and the frames and feed rollers vertical. To cut at an angle the bed, and consequently the feed rollers, are tilted, the rollers being afterwards brought to the centre opposite the saw by moving the shaft upon which the bed is pivoted up the quadrant. To rotate the feed rollers, the shaft supporting the bed is revolved, and a worm wheel upon its centre, between the quadrant guides, made to gear with a similar wheel upon a sleeve on the left and right hand screwed shaft. On the sleeve are secured mitre wheels, which gear with mitre wheels upon the shaft of the feed rollers, each pair o feed rollers being geared together at their opposite endsf Claims: (1) An improved feed, which can be used for the various purposes such as described; (2) the canting of the feed rollers, so as to cut at any angle, from vertical to horizontal, such as described; (3) the arrangement whereby the feed rollers can have any lead required given them towards the fence when they are in the horizontal position; (4) the guide rollers constructed so as to act either as a table or fence.—No. 9851. June 15th, 1889.

CASTING METAL.—*G. Höper, Westphalia, Prussia.*—This is a method for the manufacture of dense metal castings to be afterwards rolled into sheets or formed into wire. The castings are

Digitized by Google

made of annular form, and the moulds are rotated about their axes during the casting and until the metal has solidified. The inner opening of the annular casting can be formed either by the introduction of a core into the mould, or, without such a core, simply by the centrifugal force imparted to the metal by the rotation of the mould. With horizontal moulds the casting is effected either from the centre or from the circumference, but in vertical moulds it is best effected from the centre. The casting made in these moulds shows great density, with the fibre of the metal lying in a circular direction. To make wire the moulds are made spiral. Claims: (1) The process for the production of dense castings for sheet metal and wire manufacture wherein annular discs are formed by running metal into revolving moulds as described; (2) an improved manufacture of annular rings or discs produced in the manner set forth in the preceding claim, such rings being, when required, formed into bars by cutting through and straightening them out; (3) the use for the process referred to in claim (1) of rotating casting moulds, the speed of rotation being such that the central hole of the cast disc or ring is either produced by centrifugal force or by a central core; (4) in the manufacture of annular discs such as are referred to in the claim (2), the method of cutting spiral grooves on the surfaces thereof for facilitating the cutting of the disc into a spiral strip.—No. 1754. February 1st, 1890. 8*d.*



ELECTRICITY.

ELECTRIC LAMPS.—*H. Pieper, Liége, Belgium.*—In lamps of this description the light is produced by means of a carbon rod and two or more electrodes in contact with one end of the rod, so that when the electrodes are excited the current passes transversely through the carbon. The improvements will be understood from the following explanation of the lamp, referring to the illustrations. Fig. 1 is a sectional elevation of the lamp, and Figs. 2 and 3 a section and elevation of the carbon rod. In Fig. 1, A is the carbon and B C are the two electrodes. These are pivoted at D and E to the respective posts G and H, which are fixed to the plate F, but insulated from it. The post G is provided with the binding screw I, and the post H with the binding screw J. The electrodes are drawn by springs K and L against the end of the carbon rod, which in turn presses by gravity and by a weight M against the latter. A current introduced at I will, consequently, pass through the post G and the electrode B to the carbon A, and, after having traversed the carbon, it flows through the electrode C and the post H to the binding screw J, the carbon being, in consequence, caused to become incandescent at its end. In order

FIG. 2.

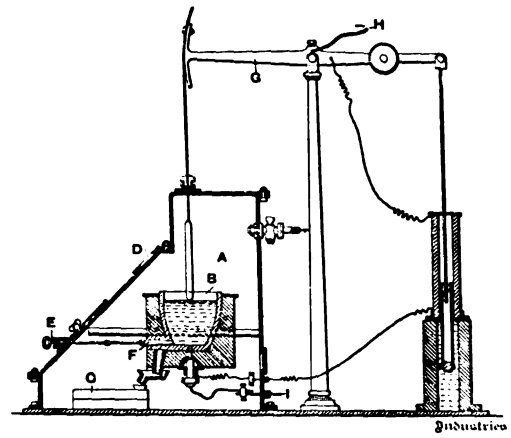


FIG. 3.

FIG. 1.

to avoid the transmission of the current through the pivots D and E, it is advantageous to connect the posts G and H with the respective electrodes B C by means of wires N O. If the carbon is consumed unequally at its points of contact with the electrode, the latter will still remain in contact with the carbon by reason of the spring adjustment. To keep the electrodes cool, they are made tubular to permit a current of air to pass through the interior. The lamp is switched out of circuit automatically when the carbon rod is nearly consumed by the contacts P Q striking the contacts R S and connecting the electrodes up through the wires T U. It may be seen that by this construction, if contact is made upon either side by part of the carbon rod fracturing, the lamp will be likewise switched out of circuit. Claims: (1) In an electric lamp, the combination of a carbon rod, an electric circuit, two or more electrodes in contact with one end surface of said rod, one or more of the said electrodes being movable with its, or their, contact point or points lengthwise to the rod, and means for pressing the movable electrode or electrodes against the end surface of the same, substantially as described; (2) in an electric lamp, the combination of a carbon rod, an electric circuit, and two or more electrodes in contact with one end of the said rod, one or more of the said electrodes being tubular and inclined upward from their points of contact with the carbon, substantially as specified; (3) in an electric lamp, the combination of a carbon rod, an electric circuit, two or more electrodes in contact with one end of the said rod, one or more of the said electrodes being movable, means for pressing the movable electrode or electrodes against the carbon rod, contact surfaces on the movable electrode or electrodes, other contact surfaces arranged opposite thereto, and each of which is conductively connected to the pole of the lamp being of different denomination from that to which the corresponding movable electrode is connected.—No. 10801. July 4th, 1889. 8*d.*

ELECTRIC FURNACES.—*E. Taussig, Badrenfeld, Germany.*—The object of this invention is to provide for the casting of objects with a smooth non-oxidised surface, and to avoid the disadvantages arising from the admission of air during the melting and conveyance of the molten material to the casting apparatus and moulds. The metal is melted in a crucible B by electricity. The crucible and the moulds C are enclosed in a chamber A, from which air is exhausted by any suitable means. To watch the

process the chamber A is provided with windows D. The metal is poured by withdrawing the plug F attached to the handle E. The heating device consists of a negative carbon-rod G, which is suspended with a Siemens electric furnace upon a balance lever G. H and I are the negative and positive wires, leading to some source of electricity. Claim: The method of melting and casting metal in a rarefied atmosphere consisting in arranging an electric melting-furnace of suitable construction, with the casting apparatus and moulding boxes in a chamber within which the air may be suitably rarefied during the melting and casting, with means for controlling said parts from outside the chamber without disturbing the atmospheric pressure in said chamber.—No. 20223. December 16th, 1889. 6*d.*

ELECTRIC MOTORS.—*L. B. Atkinson, London.*—It is known that, in that class of motor in which the alternating current passes both through the magnetising circuit and the armature or working circuit, the output for a given weight or size of motor is usually small, owing to the lag of the current behind the e.m.f., due to the self-induction of the circuit, and that the only way of reducing this lag is to reduce the magnetic resistance of the motor. This resistance is largely composed of the air space between the armature core and magnet faces. The object of this invention is to reduce this space to a minimum by leaving only the necessary mechanical clearance, which is effected by using the iron of the core as the conductor. To do this the motor is constructed on the principle of a "non-polar" or "uni-polar" dynamo. Several forms may be constructed, the chief object being to combine the following principles:—Calling the direction of the magnetic induction A, the direction of motion of the conductor B, and the direction of the current C, the iron of the revolving part must be divided electrically in planes parallel to C and A. Taking these principles the motor is so constructed that the current is led into the armature by sets of brushes on one end of the armature circuit, and passes once through the magnetic field along the divided plates of iron of which the armature is composed, and thence to another set of brushes. The magnetisation is produced by leading the same current round the magnetic circuit. The brushes are carried in rings all round the armature, and as the magnetic induction must pass through at least one such ring, special construction must be adopted to prevent a closed electric circuit being formed. Five claims are made.—No. 6884. April 25th, 1889. 8*d.*

CHEMISTRY.

COLOURING MATTERS.—*S. Pitt, Sutton, Surrey.* (*L. Casella & Co., Frankfort-on-the-Main.*)—In Patent No. 9214 of 1885, the inventors described a series of tetrazo compounds, whose combination with the naphthols or their sulpho-acids produced some valuable colouring matters. They have since discovered that the same tetrazo compounds can be combined with the substituted meta-diamines and meta-amidophenols with the formation of black colouring matters, which are fast and have an affinity for unmordanted cotton. The production and manufacture of these dyestuffs form the subject of the present specification. As an example of the processes we quote as follows:—34·7 kilogs. of alpha-naphthylamine disulphonate of sodium are mixed with an aqueous solution of 18 kilogs. of alpha-naphthylamine chlorhydrate and the resulting amido-azo compound into a tetrazo compound by the addition of 7 kilogs. of nitrite of soda. This tetrazo compound is poured into an alcoholic solution of 16 kilogs. of tetramethyl-toluylenediamine which contains also an equivalent quantity of acetate of sodium. The colouring matter thus produced is almost entirely dissolved, and it crystallises after the evaporation of the alcohol. Three claims are made for the colouring matters as described.—No. 7977. May 13th, 1889. 6*d.*

COATING PLATES WITH TIN.—*J. Bang & A. Ruffin, Paris.*—It is usual to cover the bath of molten tin used to coat the plates by a layer of oil or tallow, for the purpose of preventing the oxidation of the tin both in the bath and on the plates when they are removed and are hot. The use of this oil has many serious disadvantages; it is a constant danger of fire, and has to be removed from the plate whilst it is still hot by an expensive scouring operation. If the grease is removed from the plate too early in the process the coating of tin assumes a blue and yellow tint, losing its brilliancy. A complete removal of the grease has to be effected generally by a final cleansing with turpentine. By the application of the invention to the process of tinning the oil is dispensed with. The tinning is conducted in a chamber deprived of free oxygen, but filled with a carbonaceous gas or air deprived of free oxygen by bringing it in contact with incandescent fuel. The chamber in which the process is conducted has a glass top to observe the operations, and has inclosed in it the tanks containing the hydrochloric acid and molten tin. The dipping is conducted by manual labour, leather sleeves being provided in the top of the chamber through which the men thrust their hands and manipulate the plates. An endless chain conducts the plates, after they are dipped, to a series of cooling chambers before they are exposed to the atmosphere. Claims: (1) The process of tinning metal plates and other objects wherein the operations are conducted in an atmosphere free from uncombined oxygen and other bodies, such as sulphur and chlorine, that will attack the tin; (2) the use, for carrying out the process referred to in the preceding claim, of apparatus consisting of an inclosed glazed chamber containing the baths of molten tin and acid necessary for the tinning operation, and having (firstly) orifices with gauntlets for enabling the workmen to manipulate from the outside the objects, (secondly) a closed aperture for introducing the objects to be tinned, and (thirdly) a refrigerated exit passage through which the objects are conveyed on a travelling apron.—No. 128. January 3rd, 1890. 8*d.*

MISCELLANEOUS.

PROTECTING SHIPS' BOTTOMS.—*T. Fisher, Holywood, Ireland.*—This invention is to prevent the attachment of barnacles and other shell fish to the bottom of ships during their voyage, without interrupting the ship's motion, and to diminish the resistance of the water. A mixture of oil and nitrate of copper is stored in a tank or other reservoir, and distributed by gravitation or mechanical agency through perforated tubes or pipes, placed at intervals along the side of the ship, and reaching nearly down to the keel. Shoulders or grooves are formed down the side of the ship along the lines of the perforations, to counteract the pressure of water against them, and to allow the escape of the mixture, which is diffused over the ship's bottom by the force of the water. Three claims are made.—No. 9085. June 1st, 1889. 8*d.*

MINERS' SAFETY LAMPS.—*T. Thomas, Pontypridd.*—Means are here introduced into the above lamps to prevent explosions by currents of air laden with explosive gases passing through the lamp, and also to provide an automatic lock for the outer shield. In the accompanying illustrations, Figs. 1 and 2 are elevations of the lamp, Figs. 3 and 4 details, and Fig. 5 a sectional elevation of the automatic lock. The lower portion of the outer shield A terminates in a base ring C (shown enlarged in Fig. 3). Air apertures D are formed in the base C and within the base is a tube E. The lower part of the tube E is screwed to a plate F, which rests upon the lamp glass G. The holes or apertures D H admit the necessary air to feed the lamp, and when the lamp is exposed to a current of high velocity the arrangement causes a

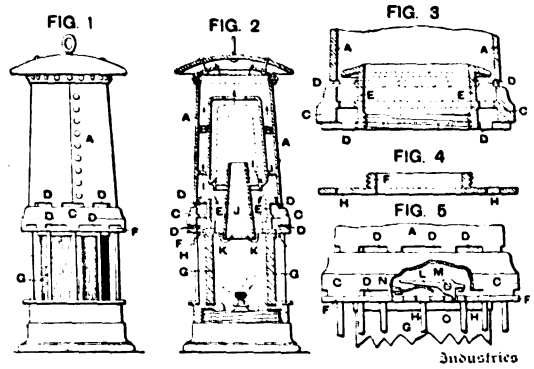

FIG. 1

FIG. 2

FIG. 3

FIG. 4

FIG. 5

whirl in the air at its entrance, so deflecting a part and admitting only the amount required to maintain a perfect combustion. Within the outer shield is a second shield B, which extends from the top of the gauze F to within a short distance of the bottom, where it rests upon the gauze by a flange I. Inside the gauze is a tube J which is supported by the flange K upon the top of the glass. The currents formed by the air and products of combustion are indicated by the arrows. The second part of the invention consists of a bar L pivoted at M about a third of its length from one end, the other end pressing on a spring N. On the under side and being a part of the bar L is a tongue O which is forced by the action of the spring into any of the holes H formed in the supporting ring F above the glass which may coincide with the position of the tongue O. The action of this automatic lock is such as to admit screwing on, the tongue being capable of gliding over the interstices, but instantly intercepts any attempt to unscrew until a special form of key is used to remove the tongue. Three claims are made.—No. 8136. May 16th, 1889. 8*d.*

Copies of the British specifications may be obtained on application to H. READER LACK, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

THE AMERICAN SOCIETY OF ENGINEERS.

(From our New York Correspondent.)

The Cincinnati meeting of the American Society of Mechanical Engineers was held from the 13th to the 16th of May. The majority of the Eastern members attending the session availed themselves of a special train of Pullman cars running from New York to Cincinnati, arriving there on the afternoon of Tuesday, the 13th. The first meeting began at 8 p.m., in the Scottish Rite Cathedral, by an address of welcome by Mr. M. E. Ingalls.

The first paper was on "The Measurement of Durability of Lubricants," by Professor J. E. Denton, of Stevens Institute. Practical differences of durability of lubricants depend, he said, not on any difference of inherent ability to resist being "worn out" by rubbing, but upon the rate at which they flow through and away from the bearing surfaces. The conditions which control this flow are so delicate in their influence that all attempts thus far made to measure the durability of lubricants have failed. The primary idea in determining durability is to supply a measured quantity of lubricant to certain rubbing surfaces, and to determine how great an amount of rubbing the lubricant will withstand before its power of maintaining the friction at some agreed upon minimum is exhausted. As a means of measuring the friction between two rubbing surfaces there is no device superior to what is known as the Thurston form of oil tester, which consists in forcing a pair of brasses in opposite directions against a journal by a spring, which latter is contained in a pendulum free to swing about the journal under the influence of the friction, the amount of friction being measured by the inclination to the vertical of a line joining the centre of the journal to the centre of gravity of the pendulum. Suppose one of these machines to have a journal about 1¼in. square, then an amount of oil forming a single drop let fall from the sharp point of a steel rod ⅛in. in diameter will cover the rubbing surfaces, so that with these surfaces in the very best condition a very low coefficient of friction can be obtained with a pressure of 75lb. per square inch on the journal at a rubbing speed of about 200ft. per minute, and at the same time there will be no surplus oil. If under these circumstances we run the journal continuously until the friction, after remaining practically constant for a considerable time—half an hour at least—gradually increases until it is double the original amount, it might easily be supposed that the number of revolutions necessary to accomplish this would measure the durability of the lubricant used as compared with another tested in the same manner. This was the opinion of the author, and in making tests in this way it was found that after about 10,000 revolutions with a standard lard oil the friction might have increased to double the minimum, but the appearance of the oil would show no signs of deterioration. It was found that the cause of the extra friction was the uneven distribution of the oil over the rubbing surfaces. There being no continuous supply, the oil distributed itself more or less by chance, and part of the rubbing surfaces could be seen to be devoid of oil. Accordingly the oil was redistributed and the pressure reapplied, and the friction at once assumed its minimum value, showing that the oil was in no sense worn out. The machine would therefore be run until the friction again doubled itself, when the same trouble might again be found. Finally, after several redistributions of the oil, the latter had lost its translucent appearance and oily nature, having become a dark-coloured paste. The total number of revolutions to produce this result might be 12,000 with lard oil on a first trial, and the same number might be obtained on a second trial. In fact, so far did duplicate trials of the same oil give the same revolutions within a small per cent. that the relative durability was thought to have been determined by this method with reference to lard oil. But upon a more extensive trial with the standard oil, 30,000 revolutions were required to reduce it to the gummy state, and again 60,000 revolutions, and upon one occasion 400,000, and in between these figures would occur records of 10,000, 7,000, and as low as 5,000 turns of the machine, which, with no variation of pressure, temperature, speed, atmosphere, amount of quality of oil, were the apparent measure of the durability of this standard oil. Upon analysing this black paste, Dr. C. B. Dudley, chemist of the Pennsylvania Railroad at Altoona, found that it was composed mainly of the materials of the bearings themselves, showing that the limit of the friction-producing qualities of a lubricant tested in this manner was the rate at which it adulterated itself with the metal worn off the bearings. This rate of metallic wear being infinitely variable, it is evident that the durability of the oil cannot be measured by restricting our measurement to the behaviour of a fixed quantity whose amount shall be so small as to allow of no surplus oil about the bearings. An attempt was then made to determine the durability by allowing a slight surplus of oil applied by a plan which would enable the surplus to be employed to secure regularity in the distribution of the oil over the rubbing surfaces. In spite of every precaution the successive records of lard oil were 82,000, 67,800, 53,000, and 29,000 revolutions, while trials with a pure mineral oil of about the same fluidity as lard gave 36,000, 33,000, and 27,000 revolutions. These last results were calculated to lead the experimenter to the belief that this method gave duplicate results, but on continuing the test one record was 10,600, while a second was 64,000 revolutions, with practically the same conditions. It was evident, therefore, that irregularity of conditions existed of a nature beyond the reach of any available means of control, and probably there is no method of employing so little oil on a journal as to prevent its escape from the latter, and determining anything representative of the quality of durability. The economy of one oil over another, so far as the quantity used is concerned—that is, so far as durability is concerned—is simply proportional to the rate at which it can insinuate itself into and flow out of minute orifices or cracks. Oils will differ in their ability to do this—first, in proportion to their viscosity; and, second, in proportion to the capillary properties which they may possess by virtue of the particular ingredients used in their composition. Where the thickness of film between rubbing surfaces must be so great that large amounts of oil pass through bearings in a given time, and the surroundings are such as to permit oil to be fed at high temperatures, or applied by a method not requiring a perfect fluidity, it is probable that the least amount of oil will be used when the viscosity is as great as in the petroleum cylinder stocks. When the oil must flow freely at ordinary temperatures, and the feed of oil is restricted, as in the case of crank-pin bearings, it is not possible to feed such heavy oils in a satisfactory manner. Oil of less viscosity, or of a fluid approximating to lard oil, must then be used, and the differences among such oils, with respect to the quality of entering and leaving the spaces between the bearing surfaces, probably depend in a considerable degree upon the differences of capillary property arising from choice of ingredients forming the mixture. It seems hardly possible that the quality of durability in lubricants can be measured, except by copying in a very perfect manner the exact conditions of arrangement, proportion, and method of feeding, which are to be used where the lubricant is to be applied, and even when this precaution is taken, the fact that in some kinds of service the limit to the consumption of oil depends upon the extent to which dust or other refuse becomes mixed with it, as in railroad car lubrication and in the case of agricultural machinery, makes it almost hopeless to expect that laboratory tests can contribute very much of practical value in the determination of relative durability of lubricants.

In the discussion following this paper Mr. Thomas R. Almond, who manufactures a coupling for connecting shafts at an angle, cited an example in which one of his couplings was charged in the oil case with a half-pint of "electric" machine oil, and after running for a number of months the oil was removed and was found to be from appearance in the same condition as when first put in, but when the same quantity of the oil from the same can was put in the case the coupling ran warm for some time, apparently showing that the oil improved by use.

Mr. George S. Strong, of the Strong Locomotive Company, called attention to the fact that on many new locomotives beeswax and plumbago were first fed to each cylinder in large quantities until the cylinder was highly polished, and after that no lubricant was used, in some cases the service extended over ten years with no oil.

The next paper was on "Some Experience with Crane Chains," by Mr. C. S. Dutton, of Youngstown, Ohio. A power crane, of 25 tons capacity, built about fifteen years ago, was equipped with a chain of 1¼in. iron, running over 16in. shears. The winding drum was 20in. diameter, and the grooves were so deep that the chain did not touch the bottom. As this chain was badly worn a new one was ordered, and within two weeks it broke under 18 tons, and a second break occurred under a 12 tons load. An examination showed that the iron was "cold short," and a chemical test gave ·00125 of phosphorus, and a new chain was made. To secure good chains the materials should be inspected before manufacture and the workmanship after. Giving a piece of chain a mild pull in a testing machine enables the manufacturers to certify that it has been "tested," and may occasionally open a particularly bad weld, but can serve no other useful purpose. The ability to stand bending cold is the most important quality of chain material, because that is the principal, if not the only, cause of chain failure. In fact, for this purpose the cold-bend test will usually show all the engineer wants to know of the material.

In the discussion, Mr. G. C. Henning stated that 95 per cent. of the strength of the bar was now guaranteed by the electric welding process, and there should therefore be no difficulty in obtaining chains that were practically safe against giving way at the weld.

The next paper was by Mr. George H. Barrus, of Boston, on "Memoranda Regarding the Indicating of the Engine of the Steamer 'City of Richmond.'" As many of the members had gone to Europe on this steamer the paper was of special interest. The paper gave sample cards, together with the data found therefrom and the estimated coal per i.h.p. per hour.

The second meeting of the Convention began at 10 a.m. on Tuesday, the 14th. The report of the Committee to memorialise Congress to provide a suitable method of perpetuating the memory of John Ericcson was presented, and afterwards the report of the Committee on "A Standard Method of Conducting Duty Trials of Pumping Engines" was handed in, and was referred back to the Committee, that the members might have an opportunity to study the report before final action was taken. The report is practically the codifying of the methods now in common use, and the establishing of a common basis on which to compare the economy of different engines. It is proposed to establish a new unit. At present the duty is estimated on the basis of 100lb. of coal, and it is recommended that this basis be abolished and that 1,000,000 heat units be hereafter used. Provision is made for separating the performance of the engine from that of the boiler, and contract clauses are framed for each case—that is, when the whole plant is furnished by one party, and also when part is furnished by one contractor and part by another. On the heat unit basis it is proposed to make the computation from the quantity of heat supplied to the complete plant, and the scope of the test should be so broad that the steam passing through the cylinders of the engine, as well as that used by each accessory, such as feed pumps, jackets, &c., should be separately determined. To determine the work done the use of the so-called Venturi tube inserted in the delivery main is advocated, and also the employment of nozzles or other similar means of indirect determination is recommended. It is further recommended that the work of overcoming the friction of the water in passing through the passages and valves should not be included in the desired total, but that that of the delivery and suction mains should be included in computing the duty: the data to be determined being the indication of pressure and vacuum gauges attached to the delivery and suction mains and the vertical distance between them. Equations are given for the computation of the results and a form for the data and results. Minute instructions are given as to the apparatus and method of attaching, and the report is a decided advance in the direction of making exact duty trials.

The next report was that of the "Committee on Standard Tests and Methods of Testing Materials." This Committee sent duplicate samples to the principal parties interested in testing several years ago, and reports were received from many of these parties. The reports varied so much in methods and data that the Committee found it impossible to formulate or tabulate these results. A second set of specimens, 236 in number, were sent to 24 different parties, together with a form to be filled out requesting tests and results; ¾in. round steel and iron, and flat or square steel and iron specimens were sent to each party. Complete results were received from sixteen parties. At the same time inquiries were made as to the work done abroad, and results of the Munich Conference of 1884 and the Dresden Conference of 1886 are given in an appendix. Generally, the Committee did not find it advisable to recommend the use or adoption of any particular form of testing machine, as there are a number now in daily use which, when kept in good repair, give good results. The use of the form of wedge holders in almost universal use is strongly deprecated, as the results are invariably lower than those given by good forms of holders. Although very desirable, no recommendations are made as to abrasion tests of straight or curved rails, as the Committee had not the necessary data. The Committee gives general recommendations as to the necessary conditions of testing machines, holding appliances, standard apparatus for routine testing, and standard drop test apparatus. The tests to be carried out with rails, axles, tires, wrought iron, low steel and high steel for structural purposes, wrought iron and low steel for boilers, materials used in shipbuilding, wire and wire rope are given, with recommendations as to the method of carrying out each of the required tests. The shape of test pieces for all kinds of testing is given. For round pieces in tension each piece should be turned in the centre ·8in. diameter, 8·8in. long, then coned towards each end to 1in. diameter in 2in. length, then carried along cylindrical for ·8in. and filleted to ½in. radius, the ends being cylinders 1in. long by 1·6in. diameter. This is recommended for all material except copper and its alloys. Flat specimens are about as now used, 8·8in. between centres, 1·2in. wide, the ends to be 2½in. wide, the corners between the ends and centre

Digitized by Google

to be ¼in. radius. This is to be the standard size of all material less than 1in. thick. Over 1in. the specimen is to be ·4in. wide, and as thick as the material. Compressive specimens are to be 2in. long by 1in. diameter if ultimate resistance alone is required. For elastic resistance the specimens should be 10in. to 20in. long, the strain to be measured in 8in. For transverse specimens bars 1in. square by 40in. long are to be used, the bearing blocks to be 36in. apart. Wood is to be tested in 3in. square pieces Scientific tests of castings are to be made of cast pieces 2in. square or 2½in. diameter, machined down to standard sizes.

The President was directed to appoint a committee to determine a standard method of conducting tests of locomotive engines and boilers.

The next paper was by Mr. W. F. Dixon, of Paterson, N.J., on "The Efficiency of Locomotives." The object, he said, of by far the greater number of improvements which have been made in steam engines has been to improve the distribution of steam in the cylinders and to mitigate the losses arising from liquefaction during the early stages of the stroke. Objections against the shifting-link valve gear have been raised so often that many appear to take it for granted that it is a wasteful and inefficient device. While it has faults, its many advantages would seem to be a sufficient guarantee of future use as extended as its past. The principal charges against it are the slow opening of the ports for admission, and the early closing of the exhaust. A horizontal admission line and a sharply defined point of cut-off on an indicator diagram are desirable, but a considerable deviation from them is possible before a really appreciable reduction of the mean effective cut-off takes place. The excellent balanced slide valves now in use, and the supplementary port of the Allen or Trick valve, is a valuable aid in overcoming "wire drawing." It is no exaggeration to say that, with a well designed link motion, the objection of wire drawing is of no practical weight. Compression does at times become excessive. In engines like the locomotive it is undesirable to reduce the clearance spaces to less than 7 or 8 per cent. of the piston displacement, for at short points of cut-off the compression line would run off so abruptly as to reach the initial pressure before the piston has reached the end of its stroke. The reduction of indicator diagram area caused by early exhaust closure, and the large clearance spaces found in locomotive cylinders, are often over-estimated. The author has been led to the conclusion that, although the clearance spaces in locomotive cylinders are usually larger than desirable, there is a limit, pretty sharply defined, below which it is prejudicial to go in reducing them, provided the link motion is retained. That steam jacketing of the cylinders of locomotives, taken by itself and not in connection with compounding, would result in some little saving, may be taken as certain, provided sufficient means of drainage were used, but it is also probable that the expense of constructing and maintaining the jackets would more than neutralise the benefit derived. Superheating has been tried several times and as often abandoned, the difficulties being the expense of construction and maintenance, those of lubrication and of preventing the leakage of the steam around the rods. The Chicago, Burlington, and Quincy Railway Company went fully into the subject in 1870 and 1874, and found that the resulting economy was off-set by the expense of repairs. The advantages of compounding are economy in the use of steam and consequently fuel, and a more uniform pressure on the cranks. The latter is considered by many engineers as the more important, but if compounds had only this latter advantage the continuance of the ordinary single expansion engine would be assured. Locomotive engine drivers are notoriously disinclined to run with a full open throttle and to regulate with the link, but in a compound engine we have an engine that must be worked expansively and good results must follow. It may be safely asserted that no locomotive built during the past twenty years has been deficient in adhesive weight after the train is once in motion. A feature of any substantial change in locomotive design will then probably be a method of increasing the adhesion at starting, as we must now rely on deadweight, a large proportion of which is useless at other times, to get trains away from the stations.

In the discussion on this paper the necessity of improving the combustion was shown. Mr. Strong said that a locomotive boiler, when worked within its capacity, was fairly economical, as 5·5lb. to 6lb. of water could be had per pound of coal when burning 150lb. per square foot of grate, but when exceeding its capacity it is very wasteful. The necessity of some satisfactory method of determining the moisture in the steam in all locomotive trials was brought out as something in which there is at present much doubt.

The next paper was by Mr. Willis E. Hall, of Altoona, on "Working of Railroads by Electricity." The author stated that the day is not far distant when we will see railroads run by electricity from a central station. One very important gain would be the concentration of the power at one point, for a given length of line, into a few cylinders, instead of working with a number of isolated engines where the chances of condensation and radiation would be great. A number of central stations—located, say, thirty or forty miles apart—could be worked by large powerful engines, and the expansion of the steam arranged at an economical point by better and more mechanical means of cut-off than can be obtained in the present type of locomotive construction. In furtherance of a reduction of coal consumption, the use of condensing—and possibly compounding—at a central station, would raise this part of the working of the line to the highest grade of efficiency. In recent experiments it was found that an electric motor could climb a grade far greater than those climbed now by locomotives; so that in this direction we could look for a marked improvement. From a central station a greater amount of power can be supplied than it is necessary to develop at the station, and in locomotive work a reduction of perhaps 25 per cent. could be counted on. The number of moving parts, and consequently the cost of repairs, would be much less, and the internal friction of the driving mechanism reduced. The loss in electric transmission would amount, in a line 30 miles long, to some 50 per cent., which includes loss in dynamo, motor and line. This, together with the cost of necessary plant as capital, comprise the two main objections against the introduction of electricity for transportation purposes.

This paper called forth considerable discussion, and there was a decided difference of opinion as to the probability of such a change ever being made. Mr. F. A. Scheffler said that for such a plant, assuming that electric locomotives were to be used, the running expense would be simply prohibitory.

Mr. William Forsyth stated that if his line ever tried to use electrical propulsion they would build their own dynamos and motors at a cost of probably ¼ to ⅕ present prices, which would reduce Mr. Scheffler's estimate materially.

Mr. Dashiell, speaking of the increased traction of an electrical over a steam locomotive, said that, from experiments he had been making, the simple passage of a current from the wheel to the track did not increase the adhesion of the locomotive.

The next paper was by Mr. A. F. Nagle, on "Determination of the Sensitiveness of Automatic Sprinklers." All automatic sprinklers, he said, use the same low-fusing solder (155° Fahr.) for holding their outlets closed; yet the time and temperature at which the solder fuses varies considerably with different makes. This difference is due to the quantity of solder to be melted, the amount of metal with which the solder is in actual contact, the proximity of the solder joint to large masses of metal, and the strain on the solder. The purpose of the paper was to correct the erroneous opinion now held as to the actual temperatures at which automatic sprinklers open. The method generally employed is to place the sprinkler in an oven heated by a common gas stove, and note the temperature at which it opens. Such tests give rise to very different published statements of relative sensitiveness. The author was convinced that the mercurial thermometer is a very sluggish means for correctly indicating such rapid changes of temperature. Air carries such a small quantity of heat that it must be heated greatly above that indicated by the thermometer in order to make the thermometer ascend at a rate corresponding to the conditions of a fire. A hot water test would not be delicate enough, for no appreciable difference in the sensitiveness of sprinklers would be discernible by a water test. The practical difficulty is, however, with the mercurial thermometer, as it changes its readings comparatively slowly. To determine the corrections the thermometer is heated over the gas stove to, say, 300° F., and then removed and the fall of temperature noted for every ten seconds. The room was, say, at 73° F. It required some practice to keep the air around the thermometer at the same temperature as that of the room. The fall for ten seconds was then divided into the mean temperature above that of the room shown on the thermometer during that time, and the result was practically constant. In the particular case here taken it was 7·8. If, then, the rise for ten seconds is noted and multiplied by 7·8, and added to the temperature of the room, the result is the correct reading of the thermometer. But after correcting the reading of the thermometer, we have still not a satisfactory expression for the sensitiveness of automatic sprinklers; it is the quantity of heat and the time together which supply the necessary elements of comparison. The author recommends the area on a diagram enclosed between the temperature as indicated by a mercurial thermometer and the calculated actual temperature as the measure of the sensibility.

The third meeting of the Convention was held on Wednesday, the 15th May, at 2.30 p.m. The first paper presented was by Mr. R. C. Carpenter, of Lansing, Michigan, on "Tests of Several Types of Engines, under Conditions Found in Actual Practice." This paper was simply the results of a series of tests on a number of engines under the conditions in which they were working, and are of little value either as to methods or results. The same author read a paper on the "Comparative Test of a Hot Water and a Steam Heating Plant."

TECHNICAL EDUCATION AT FINSBURY COLLEGE.

The City and Guilds of London Institute for the Advancement of Technical Education, with its colleges at South Kensington and at Finsbury, is a well-known educational body, and we do not now propose to recapitulate the history of its establishment and progress. The two branches at the West End and in the City are in some respects intended to satisfy different classes of educational wants, but it is with the latter, the Technical College at Finsbury, that we are at present concerned. The college, as many of our readers are no doubt aware, is situated in Leonard Street, a thoroughfare at right angles to the City Road, and within a very short distance of Finsbury Square. The building itself is a plain rectangular brick structure, with no pretensions to architectural beauty, and, as far as its external appearance is concerned, might be anything from a warehouse to a hospital; with its internal arrangements we shall deal subsequently. On pages 532 and 533 we give a series of plans of the various floors of the building.

The instruction given at the Finsbury Technical College provides for two distinct kinds of students, those who attend the day classes and those who attend the evening classes. In the words of the official programme: "The object of the day classes is to provide for the education of—(1) Pupils who are desirous, before taking their place in factory, workshop, or studio, of receiving a scientific training of a kind that will bear directly upon industrial production. (2) Persons of either sex who wish to receive such a practical preparatory training in science or art as shall fit them hereafter to fill intermediate posts in industrial works. (3) Pupils who contemplate, after the completion of at least a two years' course at the college, entering upon the advanced scientific and technical courses of instruction, such as those at the Central Institution, Exhibition Road."

"The object of the evening classes is to provide scientific and artistic education of a thoroughly practical kind for apprentices, journeymen, and foremen and others, who are engaged during the day time, and who desire to receive supplementary instruction in the application to industries and manufactures of the principles of technical science and art."

It is expressly stated that the courses of instruction in the institute are laid out, not to prepare the student to pass examinations, but solely with the object of training him in what will best fit him to become a competent worker and thinker in the career that he has chosen. We only wish that all educational establishments were guided by these principles, and that the Finsbury College will continue to act up to them and avoid being dragged into the examination vortex.

The college is divided into five departments—(1) Mechanical engineering and applied mathematics; (2) electrical engineering and applied physics; (3) industrial and technical chemistry; (4) applied art: (5) the building trades. The students of the first three departments have, during their first year, many classes in common, and even the chemical students have to do a certain amount of practical work in the pattern shops; we shall, however, confine our attention in the present article to the Mechanical Department.

The Mechanical Department is under the care of Professor John Perry, M.E., D.Sc., F.R.S., and to his courtesy we are indebted for much of the information given and for a very interesting and instructive visit to the institution. Day students have to pass an entrance examination in elementary mathematics, and give evidence of a fair knowledge of English. The examination in mathematics includes arithmetic, algebra, comprising problems involving simple equations and geometry, the latter covering the subjects of the first two books of Euclid. After entering the college all students are required to study mathematics, and for this purpose are grouped in classes according to their attainments. The more advanced students attain to the differential and integral calculus and differential equations, with applications to thermodynamics, mechanics, and electrical engineering. Professor Perry, we understand, finds it quite practicable to teach the calculus at an earlier stage of general mathematical knowledge than is usual in most centres of tuition.

The most important course of lectures for mechanical students is that on "Practical Mechanics," which, in the second year, really develops into mechanical engineer-

Digitized by Google

ing, and includes steam and gas engines and machine design. Hand in hand with these lectures go the exercises of the students in the mechanical laboratories, and this forms one of the most interesting features in the instruction given at the Finsbury College. The illustrative apparatus and models of mechanisms, &c., in the mechanical laboratories are kept in constant use by the students, who are expected to spend a certain number of hours every week in systematic experiments. As an example, after hearing in the lecture room an explanation of the parallelogram of forces, the student is required to verify the truth of the laws stated by actual trial with an apparatus suited for the purpose, and consisting of cords with weights suspended at the ends passing over pulleys, arranged in the well-known way. Of course, on making the experiment, it is found that the correspondence between theory and practice, as represented by the apparatus, is not exact, and on investigating the cause of this the student makes practical acquaintance with the phenomena of friction, the amount of which he has to determine for each of the pulleys. There are also models showing the essential construction and mode of operation of all the principal valve gears, the leading dimensions of which can be varied. The students work in the laboratories in groups of three, and they make accurate notes of their observations and plot the results as curves. By this system of instruction, the reality of the laws, demonstrated in the lecture room or expounded in the text-book, is brought home to the student in an impressive manner by the experimental exercises, and he learns truly to appreciate the fact that those laws are not mere fictions existing only on paper, but represent very tangible phenomena.

We cannot too highly commend this method of education, and, if our space permitted, should like to dwell more in detail upon the subject. The apparatus employed is purposely made as straightforward and simple in design as possible, in order that the leading features and fundamental principles may not be obscured by a mass of subordinate detail. For instance, in the transverse testing machine for first year students, the load is applied by actual weights hung upon the beam to be tested, so that it approximates, as nearly as possible, to what is represented by the diagrams in the text-books. Another point worthy of notice, in connection with the laboratory apparatus, is that, in experiments on torsion, the strains are produced by a force-couple, and thus side pressure and bending stresses are avoided. It is hardly necessary to say that the testing of materials forms an important part of the experimental training, more especially of the second year students. The tests are of the character required in practice, and, generally speaking, extreme refinements in method and apparatus are not indulged in, as the time available is too short.

The following is a list of the apparatus employed in the mechanical laboratories at Finsbury:—

APPARATUS FOR

Illustrating triangle of forces.
" polygon "
" link polygon.
" forces in braced frames.
" inclined plane.
" friction of lapping band.
" energy of a rotating body.
" stress and strain in a wire.
" law of work.
" moments of forces.
" " parallel forces.
" efficiency of block and tackle, plain and differential.
" screw jack.
" hydraulic jack.
" laws of friction of solids.
" " " fluids.
" " torsion in wires.
" " " in strips.
" stress and strain in wires (up to 3,000lb. pull with Ayrton and Perry spring to show elongation).
" stress and strain in wires (Bailey's wire tester recording a pull of 5,000lb.).
" centrifugal force.
" bending of beams (simple for wooden and small iron or steel beams).

Bailey's bar tester (for cast iron bars, 3ft. × 1in. × 1in.), Bailey's cement tester, Thurston's oil tester, Sir F. Abel's petroleum tester for determining flashing point of oils, calorimeter for testing heating power of coal; working model of horizontal steam engine with variable travel, lap, and advance of valve; working models of link motion, Stephenson's link motion, Hackworth or Marshall radial valve gear, Joy's valve gear, Meyer's independent cut-off gear, apparatus for illustrating unwinding moment of flat spiral spring, mass controlled by vibrations of flat spiral spring, vibrations of mass controlled by cylindric spiral spring; one 2 h.p. vertical steam engine for driving oil tester and other machines, fitted with belt dynamometer for finding useful horse-power, &c.; one 2 h.p. Ayrton and Perry electromotor for the same purpose.

The workshops consist of a turning and fitting shop and a pattern shop. The turning shop is provided with several lathes, arranged for screw-cutting, two shaping machines, drills, and fitters' benches. The tools are driven from a horizontal engine, to which we shall presently refer. To familiarise the students with the different methods of transmitting power, various systems have been adopted in the shop for driving the shafting, such as ropes, belts, spur and bevel gear. Owing to the large number of mechanical students, the workshops are much too small, and on this account the students have to be divided into batches and attend the shops at different hours. This entails very heavy labour on the part of the instructor, who, it should be said, is a practical workman. Mechanical students, both in their first and second year, have to spend a certain time every week in manual work, but it is distinctly understood that this is not intended as a substitute for regular training in manufacturing engineering works, but merely as a preliminary instruction in the handling of tools. On the other hand, it is not considered necessary for those who have successfully passed through Finsbury College to spend more than two years subsequently in the shops as apprentices, since the knowledge they have acquired in the former enables them more rapidly to assimilate what they learn in the latter. Those who aspire to the higher branches of engineering are recommended by Professor Perry, after going through the shops, to devote a year to further study at the Central Institute at South Kensington. As we have previously stated, not only the mechanical but also the electrical students are expected to give a portion of their time to manual labour, and even those of the chemical department have to learn something of carpentery.

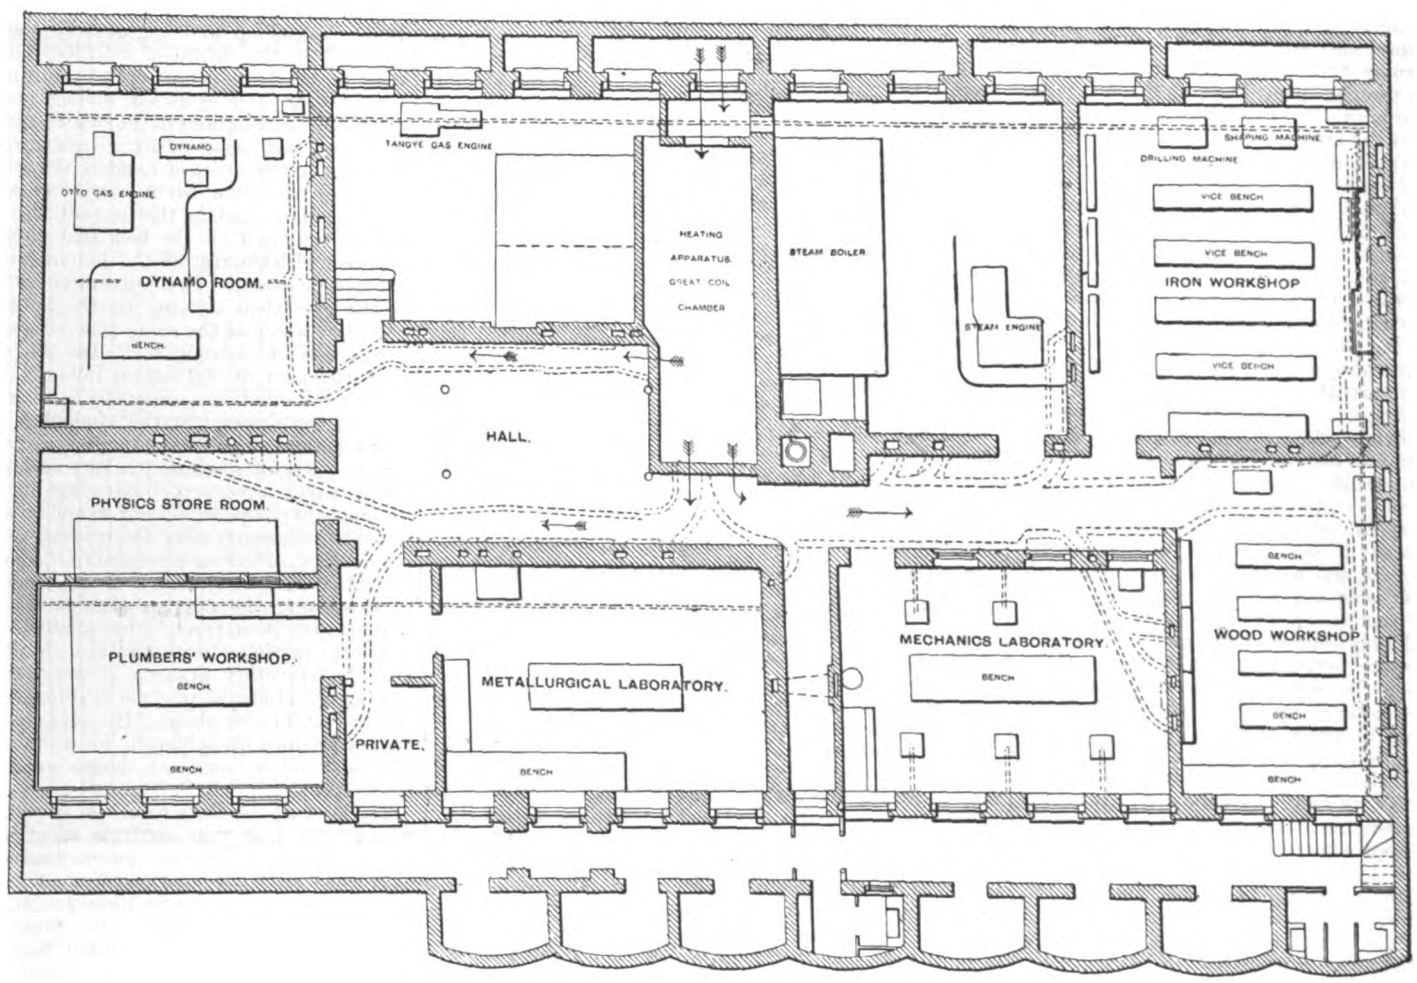
The engine and boiler room, from which power is transmitted to the line shafting in the turning shop, may be said to form a part of the laboratories, since it is here that the engine and boiler trials are carried out. The engine is a simple horizontal one, with ordinary distribution and cut-off valves, the latter being controlled by a "Hartnell" governor acting through a link. The diameter of the cylinder is 12in., the stroke 24in.; the nominal horse power is 20, but as much as 66 h.p. can be developed. In connection with the engine is a surface condenser, which, owing to want of space, is placed on the roof of the building. This condenser is of the so-called vaporising type, in which, in place of the ordinary method of circulating the condensing water by a pump, a thin stream of cold water is allowed to dribble over the exterior of the tubes, on the surface of which it evaporates. On the line shaft near the engine is one of Professor Perry's well-known dynamometer couplings, by which the power transmitted can be measured. The boiler looks on the outside like a short Cornish boiler, but it has a combustion chamber and tubes instead of the Cornish flue.

At certain times, what Professor Perry terms a "field day" is held in the engine room. On this occasion engine and boiler trials are carried out on a systematic plan; indicator diagrams are taken, effective power determined from the dynamometer coupling, feed water and coal are measured, temperatures and pressures recorded, and, in short, all observations taken incidental to a complete series of experiments on the engine and boiler. Besides this, the electrical horse-power given out by the dynamo, when it alone is driven, is determined. From the recorded results the students have afterwards to work out diagrams of various kinds. In making the engine and boiler trials three students are told off to observe each class of phenomena, and, according to a preconcerted plan, matters are so arranged that every student takes his turn at every kind of observation. Each whole group of three is not transferred bodily from one post to another, but a single student at a time is transferred from one group to another, so that the novice always works in conjunction with two colleagues who have already gained a little experience in the work.

Near the engine and boiler room is the dynamo room, which, however, appertains more to the electrical department; here, however, there is a 12 h.p. Crossley gas engine, on which the students of the mechanical department make experiments analogous to those carried out with the steam engine.

We will now turn our attention to the drawing office, not the least important branch of the establishment. It is in the charge of Mr. George Halliday, Wh.Sch. In this first year mechanical students are required to work for seven hours every week on practical geometry and machine drawing; in the second year the hours of attendance are extended to ten. Under practical geometry are included plane geometry, which embraces the construction of the parabola, ellipse, hyperbola, and cycloid, descriptive geometry, exercises in graphical statics, and valve diagrams. Machine drawing proper commences with tracing a series of working drawings of machine details, and with this the first term is generally occupied. During the second and third terms students are required to make sketches of models of machine details, and from such sketches to prepare working drawings. In the second year the students proceed to sketch and make working drawings of machines in the workshop and engine room, and are then instructed in the design of machine details. The exercises in practical geometry are continued during the second year, and extended, among other subjects, to elastic curves, diagrams of the sensitiveness of a governor, and heat and temperature diagrams of a gas engine. Situated in the heart of London, the work in the drawing office has often to be carried on with the help of artificial light, and, in this respect, the students are to be congratulated on the fact that this department, in common with the rest of the building, is illuminated by electric glow lamps; nothing is more trying and injurious to the eyes than drawing by the light of an unsteady gas flame which at the same time vitiates the air by the production of carbonic acid. On the whole, we think that the plan of instruction followed in the drawing office is a sound one, especially in view of the limited time at the disposal of the students. The practice of preparing drawings from sketches made from models or actual parts of machinery is very useful, and Professor Perry makes a point of impressing upon students the necessity of completing their sketches at once, so as to avoid the necessity, after the working drawing has been commenced, of having to return to take some dimension which has been omitted. Professor Perry is quite frank in expressing the opinion that it it only under his system that it is possible for students in a two years' course to produce "drawing office drawings." He says that in all other drawing classes with which he is acquainted, students produce drawings which would be laughed at in the shops. He says, however, that he cannot produce draughtsmen, for a draughtsman is able to design and no man can design until he has been in the shops.

The students of the mechanical department, together with all the first year students of other departments, attend a course of lectures on practical physics, parallel with which runs a series of experimental exercises in the physical laboratory; among these are included quantitative experiments in proof of the fundamental laws of gases, determination of the latent heat of steam, and calorimetry generally. Hand in hand with the lectures on mathematics, mechanics, and physics go so-called tutorial classes, in which numerical calculations are made on the subjects dealt with in the lectures. These exercises are conducted in mathematics and mechanics by Mr. Blaine and (since Mr. Crombie's elevation from the position of junior demonstrator at Finsbury to the more congenial one of principal of the Technical College at Parã, Brazil). Mr. Graham—who also superintend the mechanical laboratory—and in physics by Mr. Robinson and Mr. O'Keefe. The drawing office is under the care of Mr. Halliday and Mr. Waynforth, while the workshops are managed by Mr. Shepherd.



In addition to the experimental exercises already described, it is arranged that every mechanical student shall, at least once during his course of instruction, in conjunction with a fellow-student, take entire charge of the engines and boilers for a whole day. On this occasion he is required to make accurate observations of the performances of the machinery under his charge and furnish a full report to Professor Perry.

On the completion of their studies at Finsbury College, students are advised by Professor Perry to spend two years in an engineering workshop, and after that, if they wish to further pursue their theoretical studies, to spend a year under the instruction of Professor Unwin at South Kensington. Professor Perry very strongly recommends every student, on leaving the college, to get a job as an ordinary apprentice, obtaining, if possible, wages from the first. He insists on the advantages of a personally-conducted search for employment, and is very strongly opposed to the premium pupil system, which he considers calculated to produce loafers, and to prevent beginners from obtaining a thorough acquaintance with their work, while it does not tend to promote sympathy between them and the workmen, from whom alone they can learn their trade. We think that all who have gone through both the theoretical and practical "mill" will agree with Professor Perry as to the necessity of workshop training for the mechanical engineer, although this view does not appear to be shared by all engineering professors. It ought to be very clearly recognised that the manual training, in Finsbury and similar colleges, is not intended to, and never can, supersede experience in an engineering establishment conducted on commercial principles; on the other hand, the college offers facilities for acquiring an experimental knowledge of the testing of motors and materials, which can rarely be obtained elsewhere, in addition to the more exclusively theoretical instruction.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 3rd June, 1890.

Iron.—Here, as in the provinces, the dominant note or characteristic feature of the iron trade is hesitation. Buyers hesitate to place fresh orders, having no confidence in the stability of the existing state of things, and sellers hesitate to meet the requirements of consumers by reducing prices, fearing the continued maintenance of the present high rates for coal. Within the last few days, however, the colliery owners have manifested a conciliatory disposition, and several of the ironmasters have, it is said, renewed their contracts at prices which will enable them to make some concession to their customers. Here in Paris joists are in better demand, and the merchants have profited by the opportunity to return to the price of 160s. In the Haute-Marne business continues to fall off. As a consequence bars may now be bought at 152s. a ton, and considerably less in orders of some importance. Founders report business very slack. In the Loire-et-Centre the demand has revived a little.

Metals.—The speculative rig in copper, undertaken with a view to operations in the shares of copper mines, is running a successful course, to the great injury of the copper-consuming industries. It is to be hoped that the time is not far distant when some check will be applied to these financial operations by the legislature. Chili bars are quoted £58 and higher, and best selected, £58 10s. The other metals, except lead, have followed copper. Banca tin is quoted £102 10s., and Silesian spelter £24 12s. a ton.

The Labour Question.—The Government, without waiting for the report of the Special Commission now occupied with the projects for regulating labour, has decided to take the initiative, and to bring in at once a Bill fixing the maximum working day at ten hours. M. Jules Roche, who has charge of this Bill, proposes to introduce into it measures to ensure the complete regulation of work in factories and other industrial establishments. The working men's syndicate at Lyons are seeking to organise another labour demonstration to take place somewhere in the course of the present month.

New Iron Works in France.—The large iron works of Creusot have acquired a large plot of land by the side of the Adour, on which they are going to establish new works. It is evident that their intention is to use the excellent Spanish ores found in the neighbourhood of Irun, but they may also have in prospect the employment of Spanish coals from Asturias. A large Bilbao capitalist, who is connected with the Creusot Works, has sent an engineer to examine the coalfields of Ubies.

A Novel Wrought Iron Chimney.—The following are particulars of a wrought-iron factory chimney, of a somewhat novel description, which has been built at Creusot. The total height is 279ft., the diameter 23ft. at the base and 7ft. 6in. at the top; the total weight being 80 tons, exclusive of masonry foundations. The latter are carried 3ft. 3in. above the ground, and weigh about 300 tons. The shaft was built in successive rings, each 4ft. 1in. high, the thickness varying from $\frac{9}{16}$in. at the base to $\frac{1}{4}$in. at the top. The nine lower rings were formed of eight plates each, the upper ones of four plates each. The base was encircled by a massive angle iron bolted to the foundation. The eight lower rings were lined with fire-brick. The erection of the chimney occupied 70 days, including taking down the flying scaffold. The latter was of a somewhat novel character. It consisted of a central wrought-iron tube 7in. in diameter, and provided at the bottom with four wooden crossbars or arms, so clamped that their length could be adjusted to suit the varying diameter of the chimney, and carrying the internal platform. These arms rested on angle brackets refitted to the interior of the plates. The upper part of the central tube carried four cross-arms, or jibs, each consisting of a pair of timbers stiffened by raking struts from the central tube. From their outer ends was slung the exterior circular platform. The latter consisted of a pair of angle iron rings, to the outer part of which was riveted a plate iron fence, while the inner was provided with T-iron stanchions. Radial bearing timbers, resting on these rings, and adjustable endwise to suit the varying diameter of the chimney, carried the platform, an annular space being left just sufficient for hoisting the plates. The latter operation was effected by a rope passing over an adjustable pulley fixed to each jib in turn, and carried down a central tube to a snatch block fixed at the bottom of the chimney. As each successive ring was riveted up, two pairs of bars were laid across, by which the scaffold was slung by four jack-screws furnished with ratchet collars, and thus raised high enough to take a bearing on the next set of angle brackets. The complete scaffold weighed about 4 tons, and the heaviest plate about 8 cwt. The total cost of the chimney, without foundations, was about $8,000.

BERLIN, 2nd June, 1890.

Iron.—The iron markets of Upper Silesia continue active, and afford in this respect a contrast to those of Western Germany and abroad. The production of pig is kept up to the full capacity of the blast furnaces, and the deliveries absorb the whole of the output. The demand is brisk for all classes, for foundry as well as forge and steel pig. The market is animated, too, in all branches of the finished iron and steel trades, bars, joists, and plates being equally inquired for. It is worthy of note that wire and wire nails, neglected in the markets of Western Germany, are there in very brisk demand. Here in Berlin business is slacker, the market being influenced by the weakness of the Western markets.

Metals.—There is but a moderate current of genuine business in metals, yet the tendency of the market is constantly upwards. Obviously the movement is due to speculation. Copper has further advanced. Mansfeld refined being quoted as high as £64, and English brands up to £62 10s. Banca tin is firmer at £106. Lead is in brisk demand, and very firm in price. Spelter is quoted at last week's prices, but the tendency of the market is distinctly upward. Antimony regulus has moved slightly in favour of buyers; English, £74 to £77 5s. a ton.

The Lamp-Glass Trade.—The syndicate of lamp-glass manufacturers is not to be broken up. At a numerously attended meeting of members and others interested in the trade held last week at Görlitz, some important changes were made in the constitution of the association, and a proposal to continue it in its altered form was unanimously agreed to. This is a matter of considerable importance to the export trade.

Soap Makers' Convention.—A largely attended meeting of the Soap Manufacturers' Convention of Eastern Germany was held last week at Breslau, to deliberate on a proposal to raise the prices of soap. It was stated that the cost of all the raw materials of manufacture, including fuel, as well as the rate of wages, have considerably advanced of late, so that the present prices of soap leave no margin for profit. Resolutions were passed adopting the proposal, and prolonging the Convention, with some slight changes in its constitution.

The Import Trade in Italian Wines.—The import trade in Italian wines is rapidly growing. Excluding from the returns the port of Hamburg, the quantity received amounted to 49,583 hectolitres in 1887, 71,392 hectolitres in 1888, and 120,664 hectolitres in 1889. The latter quantity, which is equal to some 16 million bottles, is about one-fourth of all the foreign wines imported into Germany.

Beer Production in Germany.—The beer production in the beer excise district, comprising the following States, Prussia, Saxony, Hesse, Mecklenburg, Thuringia, Oldenburg, Brunswick, Anhalt, Lubeck, Hamburg, and Bremen, amounted in the fiscal year 1888-9 to 28,655,675 hectolitres, as compared with 27,475,846 hectolitres in the previous year. The industrial breweries numbered 8,540, and the non-industrial breweries 1,016. The brewing materials consumed were: Bruised barley malt, 11,185,250 ctrs. (1 centner = 50 kilos.); wheat malt, 281,058 ctrs.; other grain, 688 ctrs.; rice, 25,484 ctrs.; sugar, 75,774 ctrs.; syrup, 3,710 ctrs.; other malt substitutes, 14,088 ctrs.; total, 11,566,052 ctrs., compared with 11,094,430 ctrs. in the preceding year. The brewing tax yielded 26,645,511 marks, against 25,128,393 marks in the previous year. One centner of bruised malt yielded, on an average, 2·47 hectolitres of beer, and the excise per hectolitre amounted, on an average, to 82 pfgs. The average production of industrial breweries was 2,998 hectolitres. The excise-free breweries for home consumption numbered 40,967.

Sugar.—The consumption of beet for sugar-making purposes in the German customs district during the period from the 1st of August, 1889, to the 30th of April, 1890, amounted to 98,250,394 dble. ctrs., against 78,961,330 dble. ctrs. in the corresponding period last year. The export in April was:—Raw sugar and refined sugar under 98 per cent. polarisation, 613,507 dble. ctrs.; other sorts of sugar, 343,194 dble. ctrs. The respective quantities exported in the first-named period were 4,033,674 dble. ctrs., against 3,586,700 dble. ctrs., and 1,586,840 dble. ctrs., against 1,472,755 dble. ctrs.

Electric Transmission of Power.—The Würtemberg Portland Cement Works, at Lauffen-on-the-Neckar, has decided to utilise the large amount of water power at its disposal, in so far as it is not required for the cement factory, in the production of electric currents, which are to be transmitted to the town of Heilbronn, distant about 11 kilometres, to be used for lighting purposes and for working electric motors. In order to supply the electrical current for industrial purposes, it is proposed to reduce the cost of the installation as much as possible by the erection of thin overhead wires. The company has already applied to the State and municipal authorities for power to carry out the undertaking, in order if possible to have it ready for the winter. Mr. Oscar von Miller, of Munich, has been commissioned to design the details and superintend the execution of the enterprise.

VIENNA, 2nd June, 1890.

The Iron Market.—The situation of the iron market has altered in a satisfactory manner. Once more the syndicates have obtained a victory over speculation, and have pushed it out of the field. This result was obtained by the steadily increasing demand, which was quite irrespective of prices, and by the diminishing stocks. Notwithstanding the events in the Glasgow market, the Austrian and the Bohemian iron markets are again firm, and if the present tone prevails it would not be at all unlikely for the prices to increase. The chief ironworks and machine manufactories are now taking stock, and most of them show good results. The Bohemian Montan Company held its general meeting last week; there it was reported that the production of ores amounted to 207,925 tons. The profit was 80,000fl., and a dividend of 7 per cent. was declared. The administration of the Brünn machine manufactory will propose to the shareholders' meeting a dividend of 10 per cent. The sale of the products of the Simmering machine and waggon building manufactory amounted to 2·713 million florins, and the profit to 162,929fl. A dividend of 6 per cent. will be paid. The orders received for the new business year already represent 2·5 million florins. The machine manufactory of the Hungarian State railways had an income of more than 3,000,000fl., and a profit of 637,718fl.; this is 200,000fl. more than in the previous year. The iron and steel manufactory of Diösgyör had an income of 3,878,988fl., and a clear gain of 907,862fl., nearly 750,000fl. more than in the last year. In comparison with 1888 the profit of the machine manufactory increased by 136,200fl.; that of the iron and steel manufactory decreased by 106,600fl.

The Coal Market.—It does not appear likely that there will be any further change in the coal market this year. The demand continues very brisk, and as the strike in the Pilsen district is nearly terminated, all the business goes on much as usual. In concert with the directors of the State Railways the Prague Chamber of Commerce called a public meeting last week to consider the ways and means of preventing the congestion of traffic due to the scarcity of coal waggons, which is felt most seriously in the autumn. Deputations from the Bohemian railways, the coal works, and some sugar manufactories were present at the meeting. The meeting resolved to recommend that the year's traffic should be distributed more equally, and that encouragement should be given to consumers to procure their supplies for the winter during the summer months.

DÜSSELDORF, 3rd June, 1890.

Iron.—The Whitsuntide holidays brought a slack market almost to a standstill, a state of things that has hardly yet passed away. The languor which now oppresses the iron trade of this district shows itself in the continued downward tendency of prices. The present quotations are, it is true, little more than nominal, since there is practically no business being transacted; but the weakness makes itself apparent in the general tone of affairs, which is more and more depressed. The reductions that were made a short time ago have failed utterly to stimulate the market. On the contrary, the effect on buyers seems to have been to keep them away in the hope of obtaining still better terms later on. Spiegel pig has dropped to 98s. a ton, and Siegen forge to 78s. English Bessemer is offered at 75s. delivered free at Ruhrort. For bars there is but little inquiry, and business is very slack in hoops and wire. Joists are in fairly good demand, and there is a steady, but weaker, current of business in plates and thin sheets.

Coal.—The Berlin financial papers are publishing statements concerning the coal trade of Rhineland-Westphalia, with a view to influence the share market. These "bearing" reports have, however, no foundation in fact. So far from the coal market going to pieces, as these speculators' journals would make people believe, it is manifestly stronger than it was a week ago, and there is no prospect whatever of a collapse. Consumers are restricting their purchases till they see whither the market is tending, but the current of business is still sufficient to absorb the greater part of the output. There will be, no doubt, some accumulation of stocks at the pits as usual during the summer months, but it is certain that next winter's trade will commence with much less than the average amount of stocks in hand. Any estimate of the industrial prospects based on much cheaper fuel must therefore be fallacious.

Krupp versus Bange.—Valparaiso newspapers publish a report of shooting experiments with Krupp and Bange cannon which took place simultaneously a short time ago. Twenty-five shots were first fired from field guns to a distance of 1,000 metres. Sixteen shots from the Bange guns hit the mark, but were spread over the entire surface; whilst the Krupp cannon made nineteen hits with considerably less divergence. In testing the hill guns, 20 grenades and 20 shrapnels were fired at three marks, 20 metres wide, and 2·70 metres high, behind one another at distances of 20 metres, the guns being 1,500 metres from the butts. The Krupp cannon required 17½ minutes to fire the 20 grenades, and the Bange cannon 24 minutes. The result was as follows:—First butt, Krupp 180 points, Bange 101; second butt, Krupp 132, Bange 34; third butt, Krupp 45, Bange 11; total, Krupp 357, Bange 146. To fire the shrapnels Krupp required 24 minutes and Bange 62. The effect was as follows:—First butt, Krupp 327 points, Bange 134; second butt, Krupp 215, Bange 82; third butt, Krupp 120, Bange 35; total, Krupp 662 points, Bange 251. It should also be observed that several shrapnels burst in the Bange cannon. Other experiments were afterwards made, but the results all tended in favour of Krupp.

The Explosives Trade.—The Rhenish-Westphalian Blasting Explosives Company have declared a dividend of 15 per cent. The export trade in blasting explosives is steadily increasing.

The Bremen Exhibition.—The Trade and Industries Exhibition at Bremen was opened on May 31st. The exhibits are very numerous and well chosen, and give a good idea of the trade of that locality.

LILLE, 3rd June, 1890.

Iron.—For iron, in so far at least as this district is concerned, the situation certainly does not improve. Export orders have ceased to come in, our manufacturers being, in the present state of the markets, unable to continue the competition with Belgian and English producers. The tone of the market is therefore weaker. Manufacturers no longer maintain the firm attitude which they preserved down to the Whitsuntide holidays. On orders of considerable importance it is now easy to obtain large concessions. Bars may be bought for 148s. and less, and joists, for 150s. a ton. Thus the tendency of the market is distinctly downward.

Textile Manufactures.—Business, interrupted by the Whitsuntide holidays, has hardly yet resumed its normal course. In linen goods there is not much doing. We are now getting well into the slack season, and there will be nothing extraordinary in having to chronicle a quiet market for some weeks to come. The Roubaix woollen goods trade continues very slack, but manufacturers express themselves satisfied with the situation. It is an average season, and there are indications of a good season to come. The terminal market for raw wool is steady, with a tendency to greater firmness.

Flax and Yarns.—The demand for home-grown flax continues active, and the supply is falling short. In such circumstances prices are, of course, easily maintained. A good deal is being sold on export account. A further rise in the price of Russian flax, due to exchange movements, has checked the demand in a marked degree. For tows there is a fairly active home market, but there is not much doing on export account. Business is somewhat less active in yarns, but prices are firm, especially for the finer numbers. Jute yarns are in brisk demand and dearer.

AMSTERDAM, 2nd June, 1890.

The Royal Machine Factory.—The shareholders of the Royal Machine Factory at Amsterdam, which a short time since had to apply for a legal postponement of paying its debts, owing to heavy losses on contracts last year, have held a meeting, at which a somewhat gloomy state of affairs was disclosed. The creditors have, indeed, not been pressing their claims, and the customers have been very accommodating. In consequence, the company has been able to continue its operations and maintain its staff. On the other hand, the negotiations with the Government have not led to any results. It had been hoped that this being the Royal Factory, with 1,400 hands, and the largest establishment of its kind in the Netherlands, and nearly the only one able to turn out the largest orders for Navy and other purposes, the State would have considered it its duty to assist the undertaking over its difficulties, and to give it a good start on a new and, it was hoped, more prosperous career. But the Dutch Government has not been found willing to go beyond the maintenance of the Admiralty orders at present in hand. This has caused much disappointment among the shareholders.

The Coming International Exhibition at Amsterdam.—The Exhibition of appliances tending to minimise the dangers to the life and limb of workmen in factories and workshops promises to be a great success. The committee has received many more applications for space than it had originally calculated upon. Before the close of the Exhibition in September, an International Congress concerning the same subject is to be held in Amsterdam. Apart from that subject, accidents in mines and shipwrecks, with the means to prevent them, will be discussed at the Congress.

Dutch Sugar Refineries.—The leading Dutch sugar refineries have suffered somewhat in 1889, in consequence of the speculation in raw sugar, which drove up its price tremendously. The directors of the Western Sugar Refinery Company at Amsterdam state that they were compelled to stop operations for awhile, until the prices of the raw article had assumed a more normal level. In consequence of better methods of working upon an extended scale, a larger quantity of sugar was turned out than in 1888—viz., 32¼ million kilogs., as against 31 millions the year before. The net profits were 465,552 guilders, enabling the directors to recommend a distribution of a dividend of over 15 per cent. among the shareholders. The latter have resolved to increase the capital to 1½ million guilders, by the issue of 1,500 new shares of 1,000 guilders. It was stated at their meeting that the company has done well in 1890 hitherto, 22 million kilogs. being turned out this year against an output of 12 million in the same period of 1889. The directors of the Dutch Sugar Refinery Company have reported similar operations in 1889, resulting in a net profit of 89,189 guilders, equal to 10 per cent. on the share capital.

COPENHAGEN, 31st May, 1890.

A New Petroleum Steamer.—The "Kockum" has just been completed at the Kockum Engineering Works, Malmö, Sweden. The principal dimensions are: Length, 155ft.; breadth, 27ft. 9in; and depth, 9ft. 6in. The engines indicate 350 h.p., and the calculated speed is 10 knots. The steamer is divided into six compartments by oil-tight bulkheads. The pumping machinery is capable of discharging the cargo in three hours and a half. The ventilating arrangements are very complete, and the whole of the vessel is protected by a cover against the heat of the sun, for the sake of the cargo. She is intended for the Astrakan-Baku naphtha trade.

Railways in Norway.—The question of new railways is very much to the fore in Norway at present. Not only is the Government going in for several lines, but private enterprise is also busy. A syndicate is being arranged to build a railway from Christiania to Gjövik, the total cost of which has been calculated at 10,500,000kr. The time required for the building of the line has been put down at six years.

Swedish Wooden Villas for Export.—The firm of Ekman's Mekaniska Snickersfabrik continues to extend its business, and their handsome and practical villas of wood are now being sent to distant parts of the world. The Argentine Republic has proved a good market. A large order was received not long ago from Portugal, and in Italy, too, they have been largely sold.

Spirit Refining in Sweden.—The refining of spirits has become a regular and, to all appearances, a profitable industry in Sweden. The Reymersholm New Spirit Refining Company sold last year 7,574,372 litres, of which about half was sold to the Stockholm Spirit Company. The quantity sold last year was some 400,000 litres less than during the previous year. The gross receipts amounted to 397,779kr., and the expenses to 294,124kr., leaving a net profit of 103,655kr. In the expenditure is, however, included a dividend to the shareholders of 12 per cent., so the net profits, according to ordinary bookkeeping, amount to 235,655kr. The reserve fund has now reached 760,017kr., so it has been decided to turn 550,000kr. of this into shares and place them to the credit of the shareholders.

Strikes.—The bricklayers' strike in Copenhagen continues, neither of the parties showing any signs of weakness. The strike at the large engineering works of I. & G. C. Bolinder, Stockholm, has not been settled. The strike at the match manufactory at Jönköping has ended.

MADRID, 2nd June, 1890.

Pig Iron.—So far Spain has not been able to make hematite pig at a sufficiently low price to allow of it competing in foreign markets, and as regards the lower and cheaper sorts of pig this country was quite out of the running. It is now known that the Union Hullera and Metalurgica de Asturias, a company formed by French and Spanish capitalists, and managed by the able engineer Señor Adaro, has purchased some large iron ore mines situated between Gijon and Luanco, and that they intend to make pig iron. The ores are 50 per cent. metallic iron, with a large proportion of silicon and phosphorus. As they are also large owners of coal mines cheaply worked, they will be able to make a profit at any price above 34s. to 36s. per ton. At the present time Spain makes more pig than is required for the consumption of the country.

The Cuban Railways.—The concession of the Cuban system of railways is still undecided, or rather the decision is not yet known. It has become known that Messrs. Gibbs, of London, are at the head of the English company that has tendered for the concession, and many are therefore in favour of giving them the preference over Mr. Ivo Bosch, who is supposed to have too much work on his hands already. The Ministers are expected to decide to give the concession to the English company.

NEW YORK, 24th May, 1890.

The Coal Trade.—The anthracite coal trade is still improving gradually. The demand in April as in March exceeded the supply, and the inquiries for manufacturing and furnace sizes are excellent. The important fact in the trade is that the large companies continue in harmony as regards the tonnage shipments. The last six months of this year are now almost certain to be profitable. It is expected that prices will advance again, and the feeling in the trade is one of entire confidence as to the future.

A Big Commercial Scheme.—Chicago is to have one of the largest department store buildings in this country. The block bounded by State, Adams, and Dearborn Streets, and an alley, and having a frontage on State Street of 190ft. and on Adams Street of 350ft., has been leased to "The Fair" Corporation. This corporation is organised with a capital of $5,000,000, and at present runs a department store in a series of low buildings on the property. The corporation will at once begin the erection of a twelve-storey building to cover the entire piece of ground. It will cost $2,000,000, and will be constructed of steel, iron, and brick. The land is leased at an annual rental of $154,000, which is 5 per cent. on the valuation of $3,000,000.

North Dakota Industries.—Two industries are being rapidly developed in Dakota. Some of the German farmers have been experimenting with the sugar beet, and they have been so successful that many hundreds of others are intending to plant them this year. The temperature and the moisture of the atmosphere seem to be admirably adapted to maturing the beet to the point where it contains the greatest quantity of saccharine matter. In many places in the State there are veins of soft coal, from 3ft. to 10ft. in thickness, and in many places cropping out on the surface. If the beet crop is what it promises to be, arrangements to transform it into sugar will be made on a large scale, the coal supply being an important factor. It has but recently been determined that barley of a superior quality can be raised in the State, and the industry is rapidly reaching such a point that large quantities will be raised, made into malt, and shipped in that form to the great markets.

Double Tracks on Railways.—Before 1893 the Pittsburgh, Fort Wayse, and Chicago Railroad will be double tracked from Pittsburgh to Chicago. As soon as it became apparent that Chicago was likely to get the World's Fair, the officers of the Pennsylvania Company began holding meetings, at which the amount of traffic and business which would, no doubt, come to them from the Fair in Chicago was discussed. Many of the officials were opposed to the double track because of the expense, and it was only a few days ago that the double tracking was decided upon. The work will require an outlay of several millions. One of the highest officials in the company stated that their business had been increasing rapidly for the past ten years. Plans have been discussed for years as to the best method of meeting this increase without going to so great an expense. The company will have a large trade from the Fair, and they might as well build the track now and get the benefit of the business.

Bridges at Niagara.—The new Niagara River Bridge Bill has been signed by Governor Hill. The Bill provides for the construction of a bridge across the Niagara river about 1,000ft. north of the present railway suspension bridge. The capital is $500,000, with the power of being increased to $2,000,000, and the company is to be managed by a board of nine directors. The construction of the bridge must be begun before July, 1895, and it must be completed within five years. The company is stated to have been organised in the interest of the Canadian Pacific Railway Company, and the bridge is being built to furnish it an entrance into Buffalo.

The Jamaica Railways.—The Jamaica railways, to the extent of 65 miles, have been bought of the Government by an American syndicate for $4,000,000, of which sum $500,000 was paid down to the Government of Jamaica, and the rest is to remain in bonds and mortgage. The lines extend from Kingston to Porne, and from Spanishtown to Ewarton. These lines are to be extended to 185 miles. Two parties of engineers have been in the field for several months, and though no grading contracts have been let, bids have been received for steel rails from England and the United States. The lowest bid for rails came from Birmingham, Alabama. By the terms of the contract 12½ miles of the road must be finished each year; included in this construction will be a number of bridges and tunnels. The Government of Jamaica gives the syndicate 65,000 acres of land, and guarantees bonds to the amount of $40,000 per mile.

United States Railways.—The net earnings of United States railways for the month of March and for the first three months of 1890 show a favourable increase over the corresponding periods of 1889. The gross and net earnings of 124 railways for March, and of 149 railways for three months, compare as follows, with last year's earnings:—

	March. 1890.	1889.
Gross	$50,022,598	$44,985,561
Net	15,510,037	14,238,219
	Three Months.	
Gross	$166,628,417	$151,706,160
Net	49,117,906	43,528,074

This gives a gain of 8·93 per cent. over last year for March and a gain of 12·84 per cent. for three months. The South-Western roads show the greatest increase for both March and the three months—54 per cent. and 41 per cent. respectively. The North-Western, Eastern and Middle, and Trunk lines follow with 21 and 27 per cent., 7 and 23 per cent., and 8 and 16 per cent. respectively. The Southern roads show an increase of 9 per cent. for three months and a decrease of 7 per cent. for March. The Pacific roads show a decrease of 11 per cent. for three months and an increase of 1 per cent. for March. The decrease in both cases is due to adverse weather. Taken as a whole, however, the condition of the railway transportation business is very favourable.

PHILADELPHIA, 23rd May, 1890.

A Gas Company.—The annual meeting of the United Gas Improvement Company, of Philadelphia, was held a few days ago, and preliminary steps were taken towards the complete organisation of the American Gas Investment Company. The new enterprise will be capitalised at $50,000,000, of which one-half is to be subscribed in this country and the remainder is to be offered abroad. The capital will be distributed in 500,000 shares of $100 each, and 2,000 of these will be offered at par as founders' shares to subscribers in consideration of guaranteeing $200,000 to pay for the organisation. As soon as the organisation of the new company is effected 30 per cent. will be paid in, and the $15,000,000 thus raised will be used by paying $10,000,000 for the absorption of the present United Gas Improvement Company, and $5,000,000 to go into the concern as immediate working capital. The money to buy out the present United Gas Improvement plant covers the $5,000,000 of capital of the present company, and a surplus of $5,000,000 which the company has accumulated in addition. A meeting for the organisation of the larger company will be held next month.

A Steamship for Puget Sound.—The steamship "City of Seattle," built at the shipyard of Neafie & Levy, in Philadelphia, for the Puget Sound and Alaska Company, was successfully launched the other day. She is of steel, with two upper decks, and accommodation for 250 passengers. She is 275ft. long, 40ft. beam, 17ft. deep, and of 1,560 tons register. The engines are compound, and will drive her through the water at 20 miles an hour.

Fig. 3.

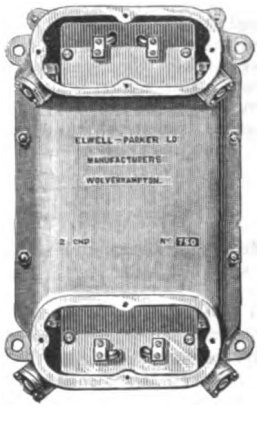

Fig. 4.

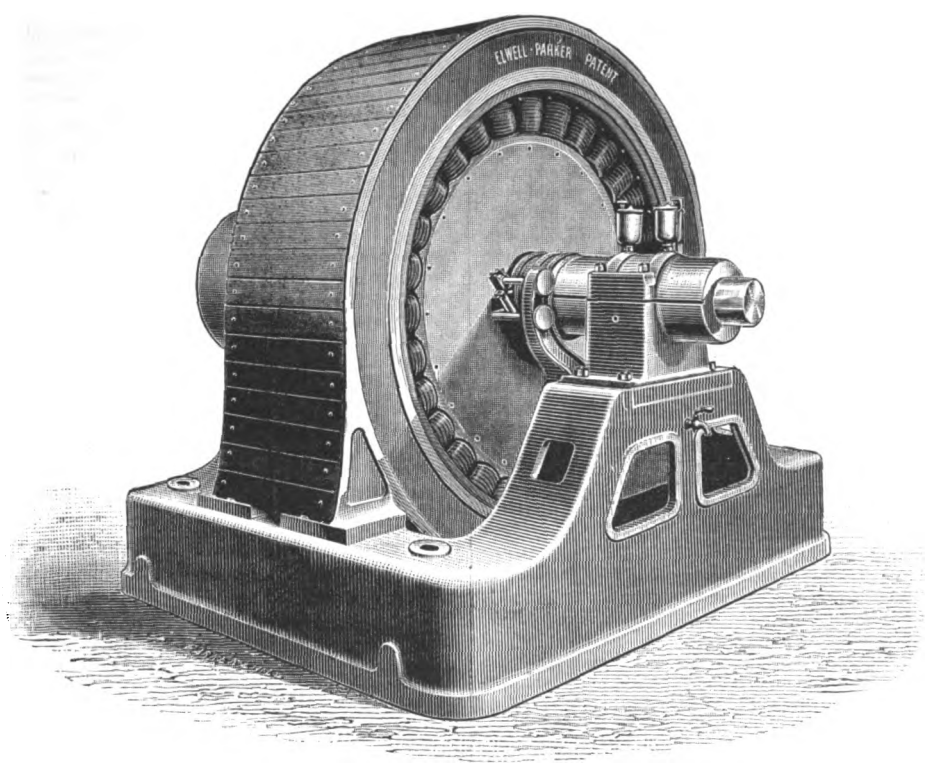

Fig. 2.—The Elwell-Parker Alternator.

ELECTRIC LIGHTING AT THE EDINBURGH EXHIBITION.

I.

In dealing with the electrical exhibits it is necessary to avoid any definite classification, and simply to take the exhibits somewhat at haphazard. Speaking generally, it may be admitted at once that there is no startling novelty. This may indeed be said of most exhibitions, since the first bloom of novelty has, for the most part, had time to wear off ere inventions find their way into an exhibition stand, to be gazed at by the instructed and uninstructed public. One thing is, however, specially noticeable in the general aspect of the electrical exhibits—that is, an increasing attention to finish in workmanship. When one remembers the badly-designed machines, and crude and ill-made fittings, that a few years ago represented the high-water mark of the electrical engineering of the time, one cannot help being struck by the improvements that, in spite of survivals here and there, have been effected both in design and in workmanship. There is still vast room for improvement, both in the unseen but most important items in an installation and in the necessarily more or less obtrusive fittings. We have to get rid, somehow, of the convention of the oil-lamp and the gaselier, and strike out a new convention adapted, and adapted alone, to the exigencies of the new order of things. Where all are by force of circumstances involved in the limitations prescribed by fashion, it would be invidious to make comparisons, but it may be suggested broadly that, notwithstanding the efforts of a few well-known firms—and to some extent because of these efforts—there lies for the expert and original designer a vast untrodden field in designs for electric fittings. In a previous notice of the electrical exhibits, we dealt with those of the Brush Company, which employs its machinery in illuminating the grounds and the interior of the buildings with arc lights; with those of Messrs. King, Brown, & Co., Edinburgh, whose machinery lights the interior with incandescent lamps and actuates some electromotors; Messrs. Ernest Scott & Co., whose alternators and transformers are employed in some of the more distant incandescent lighting in the outbuildings; and the India Rubber, Gutta Percha, and Telegraph Works Company, of Silvertown. Bearing in mind that the order in which we deal with the firms is entirely promiscuous, the next exhibit to be noticed is that of the Edison and Swan United Electric Light Company, Limited. The Edison-Swan exhibits comprise solely lamps and fittings. There is no machinery in motion. Round the stand there is a great show of lamps, numbering upwards of 2,000, and varying in power from the tiny microscope or medical lamp of a single candle-power to incandescent lamps of over 1,000 candle-power. The central case contains instruments and fittings, some of which have not been exhibited before. The instruments comprise Cardew's patent voltmeter, which the Edison-Swan Company manufacture under licence. This instrument is made in four sizes, measuring from 10 to 30 volts, 20 to 80 volts, 30 to 120 volts, and 40 to 150 volts respectively. The instrument with medium range is now made with a dial 12in. in diameter, with large figures, for use in the engine-room.

In addition to Cardew's voltmeter, the company show that of Messrs. Fleming & Gimingham. It is claimed that this instrument combines the advantages of portability and accuracy. It is adapted for measuring either direct or alternating electromotive force. The principle of its construction is that of the dynamometer. If parallel coils, one fixed and the other movable, be traversed by the same current, the movable coil will be attracted towards the fixed coil, and the force required to bring it back to its original position varies as the square of the strength of the current traversing the coils. A steel chronometer spring is used in this instrument to bring back the movable coil to its normal position. The relative position of the coils is shown by an index projecting through the dial. Resistance boxes are supplied with these voltmeters. The voltmeter being put in as a shunt, the resistance gives the current in amperes. The Fleming & Gimingham voltmeters are supplied to read from nil to 220 volts.

Digitized by Google

Among the miscellaneous exhibits of the Edison-Swan Company are their electric focus lamp for optical lanterns, a simple arrangement by which an incandescent lamp can be fixed in a lantern at any desired height, the carbon being in the shape of a square grating in which the whole luminous length of the carbon is coiled. This point of light can, by means of the adjustment mentioned, be accurately focussed. There is also a simple but efficient cut-out, which is supplied at less than a shilling; a stoke-hold fitting, with cap, to be used when the light is not required; a new ceiling plate with cut-out; a slate base with cover to be had in various metals, fastened to the base by a couple of screws; a new enamelled iron shade for high-power incandescent lamps, and a holder for lamps of large size. The company also show their well-known "Tumler" switches, and their slide rule for calculations connected with incandescent lamps.

The Electric Construction Corporation, Limited, have a varied and interesting stand. They show (not in motion) an electric tramcar for propulsion by storage batteries, and fitted with an electric bogie. This car is of the most recent type. It is suitable for running on any line of suitable gauge without any special adaptation of the permanent way. They also exhibit a 50-light EPS storage battery, consisting of fifty-five L 15 cells, 1888 type, in glass boxes. These are shown with complete fittings, as they would be in an ordinary installation. There is besides a variety of secondary cells adapted for different purposes. Among these are an L 31 glass cell giving 60 amperes in 10 hours, one L 15 cell for half this current, one for 45 amperes, and another for 22, both for ship lighting, several for train lighting, traction, boats, medical works, &c. The company also show two distributing switch-boards, one for 80 amperes and another for 60 amperes. Among the accessory instruments for use with secondary batteries are Mr. King's automatic distributing apparatus, consisting of a balance with a running counter-weight, which automatically switches in a new battery when the current of the old becomes exhausted. This is specially intended for use in central station public lighting by means of secondary batteries. It has been employed since April, 1889, by the Chelsea Electricity Supply Company.

The stand of the company is surmounted by a sign-board, the lettering upon which is picked out by 800 16 candle-power incandescent lamps. There are also exhibited a large Elwell-Parker machine and transformers. This plant consists of 100-kilowatt combined alternating dynamo and engine capable of developing 100 amperes at 1,000 volts, a supply sufficient for 3,330 lamps of 30 watts - sixteen plants of this type being supplied for the Metropolitan Electric Supply Company, Limited. The high-tension current is transformed by means of twelve Parker transformers, which reduce the e.m.f. from 1,000 volts to 100 volts. There are also exhibited two continuous current dynamos erected on tension frames in working order. Each machine is capable of simultaneously exciting the field magnets of the alternator, charging the storage battery, lighting 120 16-candle-power lamps, and running two motors. In this case these are on the stand of the Singer Manufactory Company.

In connection with electric traction there is shown the Sprague car equipment. The gear, by this method, is carried at one end by the axle, the other end being supported by springs from the car body, the intention being to secure steady suspension and freedom from vibration due to the jolting of the wheel.

Among the accessories are two types of switchboards for use with accumulators. One is suited for a current of 80 amperes of 100 volts, and is fitted with patent ring-contact switches. The second is suited for a 60-ampere circuit of 100 volts or less, and is fitted with "tongue" switches. The boards are fitted with regulating switches in order to secure that, whatever number of cells the dynamo may be charging, the lamps may be worked at their normal voltage.

Besides these major exhibits, the company show an automatic current alarm, a low constant voltmeter, an automatic make-and-break switch, and a variety of switches and fittings, besides ammeters and voltmeters. Fig. 1 on the opposite page shows the continuous current machine, Fig. 2 the alternator, and Figs. 3 and 4 the Parker transformers, one view showing the interior with the ends of the coils exposed.

SHIPBUILDING NOTES.

On the 29th ult. the "Ruskin," a steel screw-steamer, built by Messrs. Raylton Dixon & Co., Middlesbrough, to the order of Messrs. Arthur Holland & Co., London, proceeded from the Tees on her trial trip. This vessel is built on the raised quarter-deck principle, having a poop aft, and a continuous bridge deck, forming a partial awning deck. The principal dimensions are:—Length, 307ft.; breadth, 40ft.; depth, moulded, 21ft. 4in.; and dead-weight capacity about 3,650 tons. Her engines have been fitted by Messrs. Thos. Richardson & Sons, Hartlepool; the cylinders are 22in., 35in., and 59in. by 39in. stroke.

On the 31st ult. the steamer "Adder," built by the Fairfield Shipbuilding and Engineering Company for Messrs. G. & J. Burns' service from Greenock to Belfast, went on her official trial. The conditions of the trial, as stipulated by the contract, were that the vessel was to make six consecutive runs between the Clock Lighthouse and the Cumbrae Lighthouse at an average speed of 19 knots per hour. The vessel, however, exceeded the contract limit of speed, having made an average of 19¼ knots per hour. The average on the measured mile was 20¼ knots. The "Adder" will be placed upon the Belfast route on the 14th inst.

On the 31st ult. there was launched by the Campbelton Shipbuilding Company a screw steamer, named the "Dieppois." The dimensions of the vessel are:—Length between perpendiculars, 260ft.; breadth, 36ft. 9in.; depth, moulded, 19ft. 6in.,; and dead-weight capacity, 2,650 tons. Messrs. Muir & Houston, Glasgow, are to supply the engines, which will be of the triple-expansion type, with cylinders 19in., 31in., and 51in. diameter, by 39in. stroke. The "Dieppois" will be fitted with all the latest improvements for navigating and for loading and discharging cargo. She has been built to the order of Mr. Robert Delarne, Dieppe.

On the 3rd inst. the s.s. "Valin" was launched from the yard of Messrs. Wm. Doxford & Sons, Pallion. She has been built to the order of Messrs. A. d'Orbigny & Faustin Fils, of La Rochelle, France. The principal dimensions are:—Length, between pp., 250ft.; breadth, extreme, 35ft.; depth, moulded, 18ft. 6in. The engines are on the triple-expansion principle, and have been made by Messrs. Doxford; the cylinders are 21in., 33in., and 54in. in diameter, by 36in. stroke. This vessel is a duplicate of the "Reaumur," recently launched by Messrs. Doxford for the same owners.

Notices of Meetings.

NEXT WEEK.

Society of Arts.—Thursday, June 12th, at 5 p.m. "The Rationale of Indian Railways," by Sir Theodore C. Hope, K.C.S.I., C.I.E. The Marquis of Ripon, K.G., will preside.

Royal Institution.—Friday, June 13th, at 9 o'clock. Professor Silvanus P. Thompson, D.Sc., on "The Physical Foundation of Music."

PRICES CURRENT, 4th June, 1890.

Quotations at per ton, unless otherwise specified.

ANGLES, PLATES, BARS.

Messrs. G. Bailey Toms & Co., London, quote as follows:—

	Com. £ s. d.	Best. £ s. d.

Messrs. Carrick & Brockbank, Manchester, report as follows:—

Copper: A steadier feeling is observable in copper. During the week a fair amount of business in raw has taken place at fluctuating rates, chiefly on three months' account, but values generally have been maintained. As expected, the decrease in stock last month has been very large. The visible supply on June 1st was returned as about 82,000 tons (the lowest since September, 1888), showing a diminution during May of about 8,000 tons. Chili bars to-day are quoted £54 10s. to £54 15s. cash, with firm business. Manufactured quiet at £68 sheets, £71 bottoms.

Tin: No business of importance has taken place during the week, and prices have given way. The market, however, is reported stronger to-day.

Lead firm, with small business doing.

Spelter firm, supplies being small and stocks low everywhere.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

Chemicals: A large business continues to be done in sulphate of copper, and the high prices are well maintained. There is also a good inquiry for delivery late this year and into next, but on account of the upward movement in copper makers are by no means anxious to sell. Caustic soda, after a slight spurt, has given way again, and is dull at present. Bleaching powder is also weak. Soda ash is in moderate demand, prices remaining steady. Carbolic acids are firm, makers of crude asking rather higher figures.

HOME INDUSTRIES.

LONDON, 5th June, 1890.

The Money Market.—Money is rather dearer this week, although no great difference is noticeable in rates. The impression is gaining ground, however, that money must soon become distinctly dearer if the drain of gold to the Continent now going on is not checked. Of a stoppage of the efflux there is no present indication, and discount rates are hardening gradually and steadily in consequence. Dealings on the Stock Exchange are also being affected by the fears of dearer money, and the markets are rather lifeless. In spite of good holiday traffic returns home railway stocks do not show much vitality. American railroad shares depend so much on the silver question just now that in face of a declining market for the metal, and in the absence of active progress with the Silver Bill, this department is also rather quiet. Foreign stocks are fairly well supported, Egyptian and Turkish bonds being in high favour because of the conversion schemes now on the *tapis* in connection with them. Argentine securities fluctuate with the spasmodic jumps up and down of the premium on gold at Buenos Ayres, but they are inclined to improve. Copper shares have been active and firm in sympathy with the tone of the copper market. Gold mining shares have received little attention. Industrial and miscellaneous securities have been rather idle.

Companies.—The following companies have been registered since our last report:—African Exploration Gold Mining and Estate Co., Ld., with a capital of £300,000; H. D. Cooper & Co., Ld., with a capital of £20,000, to carry on the business of glass-lined piping manufacturers; Wolverhampton and Dudley Breweries, Ld., with a capital of £150,000; Anglo-American E.C. Powder Co., Ld., with a capital of £50,000; Lever Brothers, Ld., with a capital of £300,000, to acquire the business of seed crushers, soapmakers, &c.; Smith, Hollinrake, & Co., Ld., with a capital of £6,000; Siston Hill Colliery Co., Ld., with a capital of £100,000; Earl Mill Co., Ld., with a capital of £80,000, to carry on the business as spinners, &c.; The Pine Mill Co., Ld., with a capital of £100,000, to carry on the business of spinners, &c.; Electric and General Investment Co., Ld., with a capital of £200,000; Sjalati Gold Mines, Ld., with a capital of £150,000, to acquire mines, &c., in the Transvaal; China-Clay Union, Ld, with a capital of £800,000; Manchester Glass Bottle Co., Ld., with a capital of £10,000; Caerphilly Brewery Co., Ld., with a capital of £50,000; The Bohmer (Central Andes) Mining and Explorations Co., Ld., with a capital of £200,000.

Railway Companies.—The gross receipts of the twenty-three principal railways in the United Kingdom for the week ending the 25th ult. amounted, on 16,159¼ miles, to £1,470,416, and for the corresponding period of 1889, on 16,031 miles, to £1,274,240, an increase of 128¼ miles, or 0·8 per cent., and an increase of £196,176, or 15·3 per cent., the receipts this year including the first portion of the Whitsuntide traffic.

The Lane Fox Patents.—The Lane Fox Electrical Company have issued a circular, which we have been asked to publish and which we insert on another page. The company set forth some of their claims to work patents, which have been dormant for so many years. They state that Messrs. Crompton & Co. and the Swan United Company have obtained exemption from proceedings for infringement prior to December, 1882. The company repudiates the idea that their only mission is to collect royalties, and declare that they desire to carry on a general electrical and lamp-making business. They give no indication as to the amount of the royalty, but say that it will be small "if the company is fairly met." Attention is called to the fact which we had in mind when we noticed this matter three weeks ago—viz., that from 1878 till 1883 Mr. Lane Fox worked out and applied the system of parallel distribution, in the face of ridicule which had hardly ceased in 1881. The circular refers to many abortive attempts to regain possession of the patents, and to the agreement which was made at the close of the litigation between the Brush Company and the Edison Swan Company, each of these parties obtaining licence to use the patents. Mr. Lane Fox is said to have declined "many times" to join a "ring' proposed by "competent financiers" to control his inventions, and is declared to wish "to liberate, and not to strangle, the electric lighting industry."

Steam Boiler Fluid.—We have received from Messrs. Sydney Minns & Co., Trafalgar Road, Dalston, London, N.E., a small pamphlet referring to their special boiler fluid, and containing analyses of typical waters and ordinary forms of boiler scale. Messrs. Minns claim to treat the question of boiler incrustation on a scientific basis. In the pamphlet before us, they state: "We commence by obtaining a sample of water, analyse it, and prescribe accordingly."

Society of Engineers.—At a meeting of the Society of Engineers, held at the Town Hall, Westminster, on the 2nd inst., a paper was read by Mr. Perry F. Nursey on "Pick's System of Manufacturing Salt *in vacuo*." Dr. Pick's vacuum process is based on the Rillieux, or triple effect, system. The apparatus is made in three duplicate sections, each consisting of four main parts, namely, the boiling chamber, the heating chamber, the collecting chamber, and the filtering chamber. The steam used enters the heating chamber of the first section, and there heats the brine, and the steam given off from that brine enters the steam chamber of the second section, and heats the brine there. The same process is repeated in the third section. The steam generated in the latter section from the brine is drawn off by means of a vacuum pump condenser. The advantages were stated to be a saving in fuel, in labour, and in area occupied, and the avoidance of the production of deleterious gases.

Agricultural Show.—The meeting of the Bath and West and Southern Counties Society for the Encouragement of Agriculture, Arts, Manufactures, and Commerce commenced to-day at Rochester, and will close on Tuesday. The feet run of machinery in motion is 840, as compared with 616 at Exeter last year; and of agricultural implements 3,510ft., as compared with 3,465ft The special features include a working dairy and butter making competitions.

MANCHESTER, 5th June, 1890.

Discovery of Salt Beds.—Two important discoveries of salt deposits have been made. The borings which have been going on at Barrow-in-Furness on Walney Island have resulted in the discovery of an extensive bed of salt. Sinking operations, which have been carried on near Winsford, in Cheshire, have also resulted in the discovery of brine at a depth of 74 yards. The brine is equal to that generally found in the Cheshire district.

The Iron Trade.—Owing to the prolonged holidays, there has been practically no business done during the past week. The market continues to be a very slow one, and buying is on a small scale. Pig iron is only bought for immediate wants, and there is little testing of prices. The continued downward tendency in the large markets is causing buyers to be very cautious in their purchases.

The Cotton Trade.—The quarterly balance sheets of some large spinning companies have just been issued, and are very favourable. Among them are the following:—

	Capital. Share.	Loan.	Profit.	Dividend per Cent.
Crawford ...	£55,960 ...	£90,980 ...	£3,300 ..	
Arkwright ...	37,418 ...	56,726 ...	2,155 ...	10
Gladstone ...	48,542 ...	28,564 ...	856 ...	10
Duchess	35,000 ...	48,153 ...	1,248 ...	10
Star	49,000 ...	65,359 ..	2,025 ...	

All spinners of medium counts are at present doing very well, despite the increased price of cotton. Particulars of the proposed rules under the Indian Merchandise Marks Act are to hand. Those relating to cotton goods provide for the examination and testing by the Customs authorities. In testing yarns nine hanks of varying weight are to be tested, and the average taken. A test of bundles up to 1 per cent. of the whole consignment must be made, if the importer desires it, free of cost to him, but he may, if he chooses, have 10 per cent. tested by paying the cost of such examination. The latter is the extreme limit, and if the tests are not satisfactory the consignment may be refused. Piece goods are to be examined only if the Customs authorities are informed that they are inaccurately stamped. The informant is to deposit a sum as security, which can be forfeited if the information is wilfully false. The only important feature in the section relating to false descriptions of yarns is in the fourth paragraph. It is provided that if the average length of a bundle is less than 815 yards, the description shall be held to be false. This is likely to be modified in accordance with the recommendations of the Manchester and Glasgow Chambers of Commerce, who desire to fix the allowance at 2½ per cent.

The Linen and Jute Trades.—The business done last week surprised most people. As a rule, in the North, Whitsuntide from a commercial point of view is a total blank, and it is customary for the warehouses to close. During a large portion of the week this practice has been observed on the present occasion, but notwithstanding this there has been a larger trade than has been known since the time of the American war, when linen, owing to the scarcity of cotton, which could not be obtained on account of the blockade of the Southern ports, occupied, temporarily, the premier rank amongst the textile fibres spun and woven in the United Kingdom.

General Meeting of Surveyors at Burnley.—On Saturday last the members of the Association of Municipal and Sanitary Engineers and Surveyors (Lancashire and Cheshire District) held their annual meeting in Burnley. Arrangements had been made for the visitors to inspect various works in connection with the borough. Mr. F. S. Button read a paper describing the works to be visited by the members.

GLASGOW, 5th June, 1890.

Pig Iron.—There is nothing new to report in connection with the Scotch pig iron trade. The market is now in the dull season which always follows the spring shipments, and from this time till the end of July there is usually very little doing in makers' iron. This year there is, perhaps, even less doing than usual, and this arises partly from the fact that America is taking very little, and partly from the fact that makers have very little to sell. Shipments to the Continent and to the world at large are going on at a fair rate, and iron is still being taken out of store daily in quantities that were never dreamed of a year ago. Nevertheless prices droop day by day, quite regardless of the question of cost or reduction of stock.

Coal.—The dulness in the engineering trade is manifesting itself in the falling off of demand for coal for use in public works. The price is, however, in the meantime being fairly well maintained in consequence of restriction of output. Still, in dross there has been a decided break, prices having fallen from 1s. to 1s. 6d. per ton.

Local Engineering Operations.—The excavations in connection with the Clyde subway have been begun at Finnieston.—The operation of moving the new bridge carrying the Glasgow and South-Western Railway over the Caledonian line at Eglinton Street is likely to take place next Sunday. The bridge has been erected on a scaffolding immediately to the south of the existing bridge, and the girders will be moved laterally into position between Saturday night and Monday morning. The work is being carried out by Sir William Arrol & Co.

Caledonian Railway.—A new Arran express has been organised by the Caledonian Railway. A new train has been built to run in connection with the new paddle steamer the "Duchess of Hamilton.' The carriages are painted white and chocolate to distinguish them from the ordinary local trains. The train made its first journey on Friday last. It leaves the Central Station at 10.10 a.m. and 4.45 p.m., and is timed to reach Ardrossan in 55 minutes. No stoppage is made on the way.

The Forth Bridge Route.—The new route from Edinburgh, Glasgow, and the South to the North of Scotland, by the Tay and Forth Bridges, to effect which the North British and associated railways have embarked a capital of some four or five millions, was opened on Monday, the 2nd inst. On that day the regular through service of trains to and from the North, *vid* the bridges, was inaugurated. The morning express from Aberdeen at 6.20 is timed to reach Edinburgh at 9.42 a.m. and King's Cross at 6.30 o'clock in the evening—a total time of twelve hours ten minutes; while the ten o'clock express northwards from London performs the journey in twelve hours and twenty minutes. The most rapid train over the new route is that leaving Edinburgh at 5.30 a.m. and arriving in Dundee without stoppage at 6.55. On Monday the traffic was so great that the whole system was thrown into confusion by the consequent delay. The South trains were detained for the connecting trains for the North, each of which was upwards of an hour behind time in reaching Edinburgh. A considerable gale was blowing in both Firths on Monday, but no damage of any kind was done.

(From our own Correspondents.)

LIVERPOOL, 4th June, 1890.

The Leeds and Liverpool Canal.—Owing to the extension of the Liverpool dock system at the north end, the terminus of the Leeds and Liverpool Canal is now some distance from the leading docks and timber yards, and although the various railway companies have followed the trade by constructing new branch lines and depôts, the canal company has hitherto taken no steps to enable them to compete for the traffic. The directors have now, therefore, decided to extend the canal and warehousing accommodation, so as to put the undertaking on equal terms with the railway companies. The proposed extensions are on a large scale, and will involve a large expenditure both for the purchase of land and for construction.

The Belfast and Liverpool Trade.—The trade between these two ports has for many years been steadily increasing, and the business done by the Belfast Steamship Company has attained such large proportions that it has been found necessary to increase the number of steamers for carrying cattle and goods. Messrs. MacIlwaine & M'Coll, of Belfast, have, therefore, been instructed to construct two new screw steamers of 750 tons burthen each, to be fitted with all the modern improvements, at a cost of about £15,000 each.

LEEDS, 4th June, 1890.

The Iron and Steel Trades.—The position of affairs in the iron and steel trades is no more satisfactory than it was a fortnight ago. It was thought that after the Whitsuntide holidays consumers would place orders in the hands of manufacturers, but the anticipation has not been realised to the full. Nearly on all hands complaints are heard of the inactivity of the finished iron and steel trades. Prices are weaker. Engineers and locomotive builders continue fairly busy. The inquiry for agricultural machinery is much less than in the corresponding period of last year. Orders are coming in slowly, and inquiries are few The steel and iron cut nail trade remains quiet. A strike of a large character is threatened in the engineering trade. The demand put forward for a general advance of 2s. a week has met with little consideration on the part of the masters, and consequently between 3,000 and 5,000 men have handed in their notices, the majority of which terminate this week. One or two smaller firms have shown a readiness to come to terms with their men, but none of the larger houses have, it is said, in any way responded to the circulars issued by the local executive of the Amalgamated Society of Engineers. The wages of engineers at Doncaster have recently been increased, and this circumstance seems to encourage the Leeds Committee that they will succeed in what they are attempting to obtain. Whatever may be the result of the movement, it must be recognised that the Leeds engineering industry has of late declined somewhat, and that the

Digitized by Google

present prices for materials and cost of working do not admit of large remunerative returns. Yet, on the other hand, it is urged that the rate of wages paid in Leeds is less than on Tyneside and in Manchester. It is to be hoped that the dispute may be settled without resorting to a general strike.

THE COAL TRADE.—Trade in all qualities of fuel for domestic use is weaker, with falling prices. Gas coal is also in less demand, but steam and shipping sorts remain active. Engine coal and slack dull, and prices lower. Coke continues in a very depressed state. Pits are running on an average four days per week.

SHEFFIELD, 4TH JUNE, 1890.

IRON AND STEEL TRADES.—The unusually fine weather had the effect of prolonging the holidays a full week. On Thursday Messrs. Hadfields, Ld., were compelled to extinguish their fires on account of so few workmen having turned up. A good order for tires has just been placed here, and orders for the axles will shortly be placed here also. The Parkgate Iron and Steel Company have issued a notice to advance the wages of their workmen 2½ per cent. commencing the 1st June; the firm will also pay 3d per ton extra for puddling. Engineers continue well off for work. Messrs. Davy Brothers, Ld., have just shipped a powerful hydraulic forging press to the North of France, and they have also others in hand for local firms. Messrs. Wm. Jessop & Sons are progressing well with their new forge; the hammer for it is to be supplied by Messrs. Thwaites Brothers, of Bradford. The engineers of Doncaster have been granted an increase of wages.

MEANS OF TRANSPORT.—The Sheffield Canal scheme is being pushed forward vigorously, the bright prospect of the Manchester Ship Canal acting as a stimulant. The Manchester, Sheffield, and Lincolnshire Railway Company have failed to come to terms with the Sheffield Canal promoters, and will have to submit to arbitration. It is quite evident that something must be done to reduce the cost of transport if Sheffield intends to compete in the world's market. Every month brings an additional amount of work to the heavy trades, which, as yet, are not subject to much outside competition. All the raw materials for this trade have to be imported a considerable distance.

NORTH STAFFORDSHIRE, 4TH JUNE, 1890.

THE IRON TRADE.—Operations at the iron works in this district have now been resumed after the holidays, though manufacturers find some difficulty in obtaining sufficient orders and specifications to keep the mills and forges fully employed. The collapse in the trade is a complete one, and with the high cost of production prices are unremunerative. In accordance with the award under the sliding scale, an advance of 2½ per cent. in ironworkers' wages came into operation as from the 1st inst., and continues for two months.

THE COAL TRADE.—There is a downward tendency in the prices of fuel of all descriptions. Coal for manufacturing purposes is realising about 10s. per ton, and slack 5s. per ton. A good deal of anxiety is felt as to the course the miners will take with regard to the wages question. It seems almost incredible that a further advance in wages can be conceded in face of the fall in prices.

THE POTTERY TRADE.—Orders are rather more plentiful, but prices are unremunerative. There is a movement amongst the operatives to secure an advance in wages at the next "hiring" season.

CARDIFF, 4TH JUNE, 1890.

IRON AND STEEL.—The demand for pig iron is no worse. This can be looked upon as somewhat satisfactory, considering the steady decline in prices for the past five months. Ironmasters, however, have great difficulty in making both ends meet, and it is expected that other ironmasters will follow the lead of those who have damped down their furnaces. The steel rail market is fairly good, but in steel bars matters seem to be going from bad to worse. The heavy reductions agreed upon by the sellers have very little effect in bringing forward new orders. Quotations are £5 10s per ton, but business has been done as low as £5. For iron ore there is no demand, all the arrivals being under contract. Sellers maintain their quotations at about 14s. 6d. c.i.f. Cardiff or Newport, but it would be difficult to find buyers at any price.

COAL AND COKE.—The position of the steam coal trade continues extremely satisfactory, and colliery owners have reason to congratulate themselves that the wave of depression which seems to be sweeping over all other departments of industry has not, so far, affected theirs. Another large colliery—namely, Penrykyber—has been offered to the public, the capital being fixed at £35,000. The principal proprietors in the late company were Messrs. Cory Brothers, of Cardiff and Swansea, and the coal is said to be of the best. There is an eager demand for shares. Prices of steam coal range from 14s. 9d. to 15s. 3d. first quality, 13s. 6d. to 14s. 3d. second quality, and 12s. 9d. to 13s. third quality. House coal is a little weaker in tone—the natural result of the approach of summer. The exports of coal from Cardiff during the past week have amounted to considerably over 200,000 tons, notwithstanding the stoppages caused by the Whitsuntide holidays. For coke the demand is very poor, as the consumers are afraid to renew their contracts on account of the unsatisfactory position of the iron trade.

SHIPPING.—The freight market is in a state of collapse, and things are fast driving to the same position as that experienced in the years 1884 to 1886, when so many boats had to be laid up in the Tyne, Clyde, and the Tees for want of remunerative employment. Coal freights outwards to Gibraltar from Cardiff are 7s. 6d.; Marseilles, 10f.; Barcelona, 13s.; Genoa, 9s.; and Venice, 9s. 9d. Home freights from Bilbao rule at 5s. 3d. to Cardiff or Newport, and 6s. 3d. for Middlesbrough.

TINPLATES.—It is reported that the works under the proprietorship of Messrs. Wm. Williams & Co., at Upper Forest and Llansamlet, near Swansea, together with the adjoining steel works, are to be converted into a limited company. The profits, it is understood, have been exceptionally large, and there is no doubt that the excellent situation of the works, combined with the reputation which the firm has built up for itself, will induce capitalists to come forward.

BARROW-IN-FURNESS, 4TH JUNE, 1890.

HEMATITE IRON.—There is again a falling off to note in the hematite pig iron trade. The demand is much quieter, and the works are not likely to be able to maintain their present rate of output. During the week a furnace has been blown out by the Moss Bay Company, and another by the Harrington Company, leaving 45 furnaces in blast in the district, and 34 out of blast. In all probability during June three other furnaces will be blown out. Prices are easier, at 52s. 6d. per ton net for warrants, and 55s. to 58s. for makers' iron. In Bessemer mixed Nos., warrants are selling at 5s. per ton under the cost of production.

STOCKS.—A further reduction in stocks of hematite warrants is reported this week; 2,801 tons have been cleared, making a total clearance since the beginning of the year of 72,231 tons. Stocks still aggregate 308,411 tons.

STEEL.—There is a quiet inquiry in the steel trade. Rails are not in full request, and prices have gone down 5s. per ton on the week, heavy sections being quoted at £4 15s. per ton. There is a better feeling in the Siemens-Martin department, as renewed inquiries are to hand for plates and angles for shipbuilding purposes. Tinplate bars are also in better demand, but the trade, generally speaking, is lifeless. Blooms, bars, and billets are in slow demand, but hoops and wire, however, are in better inquiry. Mr. Albert Tilley, engineer for the Barrow Steel Company for many years past, has been engaged by the Martinez Rivas Palmer Company to design, lay down, and manage a new steel works at Bilbao, in Spain, for the manufacture of Siemens-Martin steel shipbuilding material for the shipyard at that place. The new works will be arranged for an annual output of 50,000 tons of finished steel.

MIDDLESBROUGH, 4TH JUNE, 1890.

PIG IRON.—The market continues dull with falling prices. Sellers want 40s. 6d. per ton for No. 3 G.M.B., and business was done at that; but as warrants could be got at less than that, the buyers would not eventually give more than 40s., and in some instances 40s. 3d. per ton. Cleveland warrants are quoted at 39s. 11d. to 40s. per ton cash, West Coast hematites at 51s. 11d. to 52s. cash, and East Coast hematites at 60s. per ton nominally, mixed numbers makers' iron, all f.o.b. The stock in Connal's stores amounted on Monday to 102,952 tons, being 3,080 tons less than on the 31st of May.

WROUGHT IRON AND STEEL.—These products are still very dull, and manufacturers cannot keep their works going full time. The holidays were largely taken advantage of, and some works are not yet reopened. Prices are drooping still more, and manufacturers are open to even less than the quoted price for a large order. Iron ship plates are at £5 7s. 6d.; angles, £5 5s.; common bars, £5 15s. per ton; steel ship plates, £6 10s.; angles, £6 5s.; steel rails (heavy section), £4 17s. 6d. per ton f.o.t. at works, all less 2½ per cent. discount. The strike at Consett has ended, the two unions having compromised matters.

IRONMASTERS' RETURNS.—Everybody expected an increase in stocks; on the contrary, there is a decrease of 12,342 tons, caused mainly by makers breaking their reserve and selling at the reduced price. The shipments were no heavier than usual, so there must have been an increased inland and local consumption.

SUNDERLAND, 4TH JUNE, 1890.

SHIPBUILDING AND ENGINEERING.—Shipbuilding and engineering establishments are increasingly feeling the result of the falling off in orders, and reductions are being made in the number of men employed. There is little likelihood that the tonnage output of the current year of the River Wear will equal that of last year, although up to the present the tonnage launched compares favourably. During the month of May eight vessels of 14,730 tons were launched, making an aggregate for the past five months of thirty-seven vessels and 81,460 tons. It is just possible that for the first half of 1890 the output will be equal to that of the corresponding period of 1889, when forty-eight vessels of 97,999 tons were launched, which was the highest record ever attained for the port. There appears to be an increasing disposition to adopt gas in place of steam as the motive power for driving shipyard machinery. Three shipbuilding establishments have now "Otto" gas engines for this purpose, the latest to have one fitted being the Sunderland Shipbuilding Company, Limited. The other firms which have adopted gas in this manner are Messrs. William Pickersgill & Sons, Southwick, and Messrs. Short Bros., Pallion.

SHIPPING.—The freight market has gone from bad to worse, and there appears to be every likelihood of a wholesale laying up of tonnage. Prompt business from the Black Sea and even in other trades must mean heavy losses on present voyages, and investors are naturally calling out for a reduction in working expenses. Bunker coals have fallen, but wages remain at the high figures to which they have been forced. In some instances the cost of insurance is unduly high, owing to vessels being covered so as to replace tonnage at the prices ruling at the close of last year. Last week there were eleven cargoes imported, consisting principally of timber, two being iron ore. Owing to the holidays the shipments of coal fell to 54,652 tons, besides which 365 tons of coke, 250 tons of patent fuel, 24 tons of nitrate of soda, and 50 tons of crystals were also shipped.

THE PETROLEUM OIL TRADE.—It is authoritatively stated that the American Standard Oil Company has purchased a site to the south of the principal wet docks, for the purpose of erecting extensive petroleum storage tanks, into which the oil will be pumped direct from oil-in-bulk steamers. The intention of the company is to make Sunderland a central distribution district. This will be a welcome addition to the not very extensive import trade of the port.

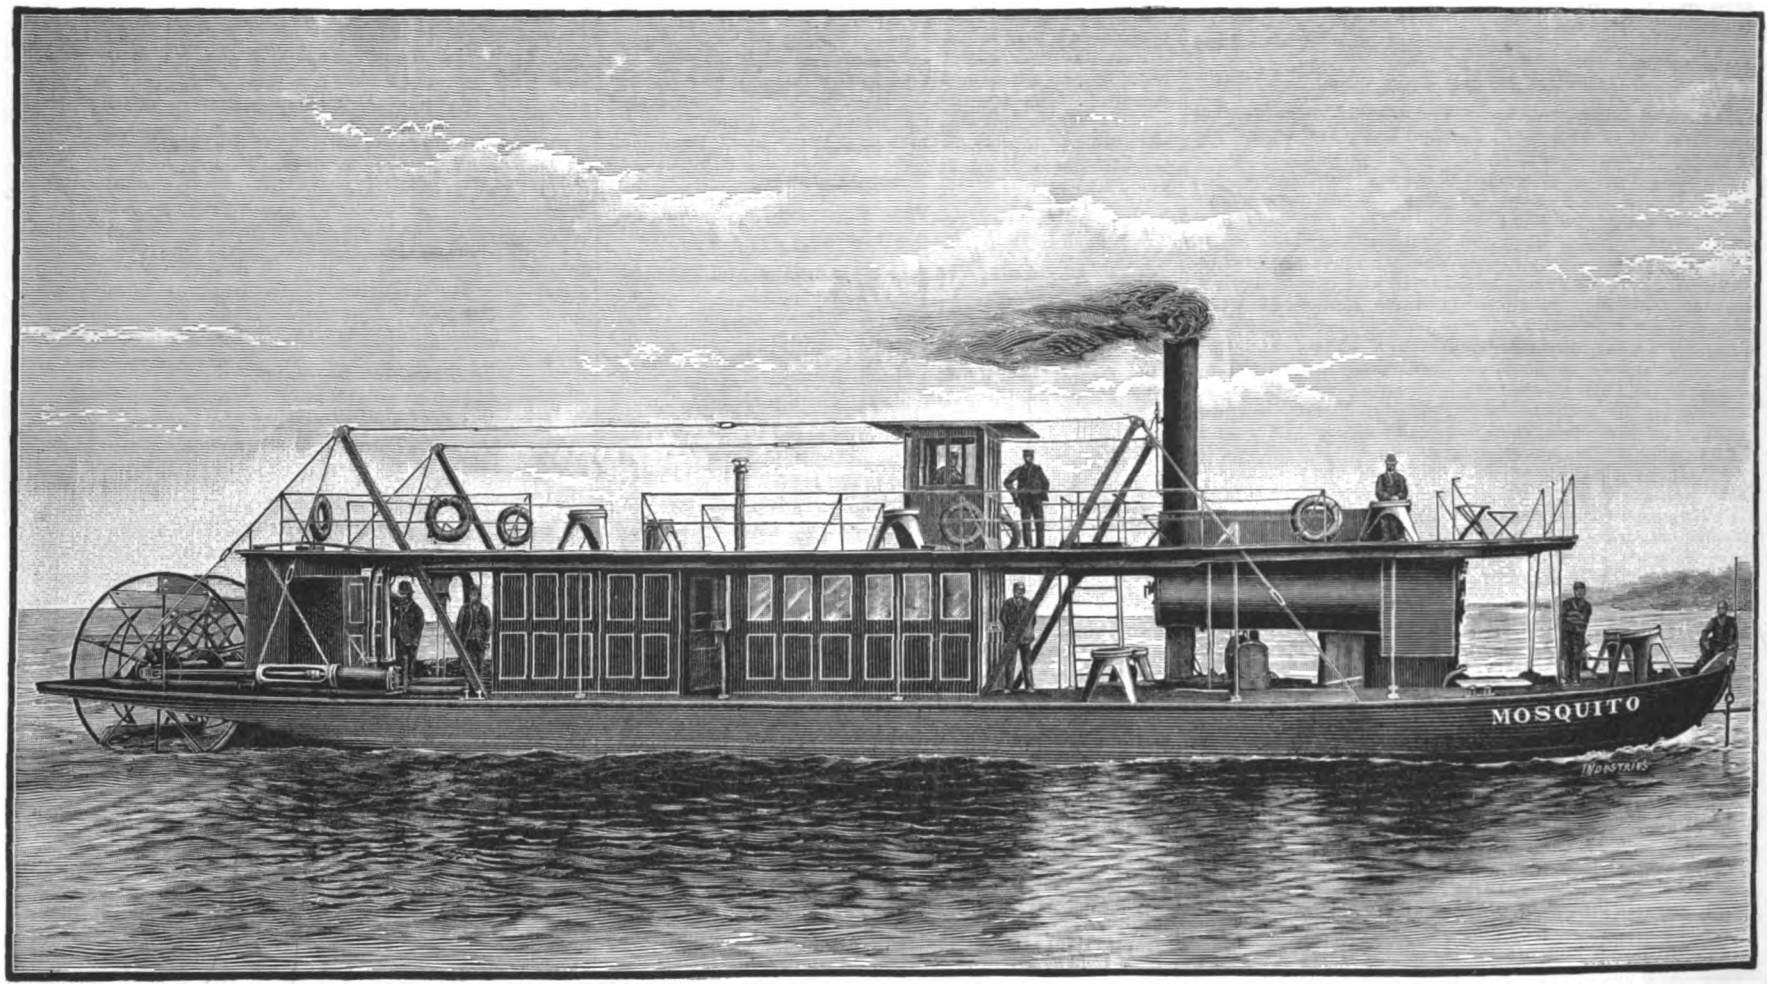
NEWCASTLE, 4TH JUNE, 1890.

THE STEEL TRADE.—A strike of steel smelters, &c., which for the past couple of weeks has caused an almost total stoppage at the Consett Steel Works, was settled on Saturday, and, though the furnaces could not be got ready for a full resumption of work on Monday morning, active preparations were in progress for the restarting of the different departments, and it was expected that before the end of the week the place would again be in full swing. The strike, it may be recollected, was the outcome of an effort by the operatives to force two or three unwilling individuals to join the Steel Smelters' Association, and thus through the merest triviality, thousands of pounds have been lost, not to speak of the serious hindrance to business caused by this arbitrary, and quite unnecessary, action of the men.

THE ENGINEERING TRADE.—Considerable dissatisfaction has been caused throughout the district by the failure of the operatives to turn in to work on Whit Tuesday in accordance with the agreement entered into with the employers by the workmen's representatives in February last, and which specified the number of holidays to be taken during the year—one only to be allowed at Whitsuntide. Though the employers were evidently disappointed by the breach of agreement, they have, up to the present, taken no steps to secure themselves against a repetition of such conduct, and it is probable that, before another holiday period has to be observed, a Conciliation Board will be in existence, by which all matters of difference can be amicably settled. In the marine engineering establishments few signs of coming slackness are yet to be noticed, but it is none the less true that very few new orders are being booked, and that unless some unlooked-for change takes place in the ordinary conditions of trade the advent of a slack time cannot be long delayed. Messrs. Noble & Lund, machine tool makers, Forth Banks, are steadily developing their business, and have now some good orders in hand from local shipbuilding and engineering firms.

GLASS WORKS, &C.—It is understood that a large number of the operatives at the Tyne Plate Glass Works have received notice of dismissal, owing to some contemplated changes in the working arrangements of the establishment. The Gateshead Stained Glass Works are very busy just now, a great many orders for memorial windows, &c., having recently been received. The glass bottle works at Blaydon are kept actively going, the weekly output being now larger than at any former time. Pressed glass works are generally busier than they were a few months ago, and potteries are also showing signs of improved business.

THE COAL TRADE.—The shipments of coal and coke at Tyne Dock for the week ending May 31st amounted to 82,990 tons, being a decrease as compared with the shipments for the corresponding week last year of 18,514 tons.



DUNDEE, 4TH JUNE, 1890.

JUTE AND FLAX TRADES.—The jute trade continues in a satisfactory condition. The market is very firm in tone, and there is a steady demand for yarns and cloth. Manufacturers are well employed, and the present briskness shows signs of continuing for some time. Advices both from Calcutta and New York are good, the improvement in the latter market being well maintained, and burlaps, 40in. 10½oz., being quoted at 5½c. per yard. A fair business has been done here in raw jute during the last fortnight. Prices have latterly been tending rather in buyers' favour. There is an active demand for jute yarns, and some good orders on foreign account were received last week. Few operations of importance in flax are reported, the advance in the rate of exchange having impeded business. Flax and tow yarns are dull of sale, and buying is chiefly of a from-hand-to-mouth character. The tendency of prices is still downwards. There is an absence of animation in the home demand for linens, but there is some inquiry from the United States in anticipation of the proposed changes in the tariff being effected.

HER MAJESTY'S GUNBOAT "MOSQUITO."

BUILT BY MESSRS. YARROW & CO., POPLAR, LONDON.

THE JAPANESE CRUISER "CHIYODA."

THIS vessel, which was launched on Tuesday last from the yard of Messrs. James & George Thomson, Limited, of Clydebank, has many features of considerable interest as compared with vessels of a similar type at present building for our own Government. The "Chiyoda" is the outcome of a design which was submitted to Messrs. Thomson by the Japanese naval architects, who appear to have been much influenced by the example of French designers; but the original design has been greatly modified, at the advice of the builders.

The Colonial cruisers "Tauranga" and "Ringarooma," which are fitting out at the same yard, are vessels of a similar type, and of about the same displacement. They have been built from the designs of our own Admiralty officials, and we give a comparison of a few of the leading dimensions:—

	"Tauranga" Class. Ft.	In.		"Chiyoda." Ft.	In.
Length	265	0	...	310	0
Breadth	41	0	...	42	0
Depth amidships	21	3	...	23	8
Mean draught	15	6	...	14	0

It will be noticed that the Japanese vessel is 45ft. longer than the "Tauranga" class, although having only 1ft. more breadth; in this respect her designers followed the French practice, so that the vessel can be driven at full speed with considerably less horse-power than the British ships. At the same time they have sacrificed "handiness," or the power of turning quickly, which will, however, be in part preserved by the large balanced rudder with which the "Chiyoda" is fitted, on a principle patented by the builders. The "Chiyoda" will be propelled by two sets of vertical inverted triple-expansion engines driving twin-screws. The boilers are six in number, of the locomotive type, and are contained in two boiler rooms.

The armament consists of ten of the well-known 4·7in. quick-firing Armstrong guns recently introduced into our own navy. As originally designed the armament was to have been supplied by a French firm, but the more modern quick-firing guns have been substituted. They will be mounted, four on each side, on sponsons, one on the forecastle and one on the poop, with a large arc of fire. The supply of ammunition will be 200 rounds for each of the ten guns, and special appliances are being fitted to enable the ammunition to be rapidly supplied to the guns. There are also three torpedo tubes, one at the bow and one on each broadside, and the ship will carry seven torpedoes, the torpedo armament being supplied by Messrs. Schwarzkopf, of Berlin. The protection to the machinery and magazines is afforded partly by the usual means of a protective deck, and partly by a belt of armour plating, which is bolted to the skin of the ship in the neighbourhood of the water-line, a feature which is somewhat novel in a vessel of this class. The protective deck has an average thickness of one inch, and extends throughout the whole length of the ship. It is formed of two thicknesses of plating, the lower one being of mild steel and the upper of chrome steel, a material which has greater powers of resistance to the impact of a shot than ordinary mild steel. The armour belt extends for about two-thirds of the total length of the ship, and gives a thickness of side amidships of 4½in. steel, thus effectively protecting the region of the water-line from the destructive effects of the smaller class of quick-firing gun, and especially from projectiles charged with melenite or other high explosive, even when fired from guns of larger calibre. Besides the main armament, an auxilliary armament of fourteen 47-millimetre quick-firing Hotchkiss guns will be carried, as well as three Gatling guns, mounted one in each of the military tops.

The accommodation for the officers and crew, numbering 300, is especially roomy and well ventilated. The crew will be berthed on the main deck, which extends for the whole length of the vessel, and which is well lighted by sidelights on either side. The officers' cabins are situated partly on the main deck aft and partly on the upper deck below the poop, where there is also a roomy wardrobe and commander's cabin. Between the poop and forecastle there is a bulwark or hammock berthing, 7ft. high, which will afford some protection to the men working the guns, as well as from the weather when at sea. The equipment of boats will be very complete, and will include a steam life-cutter with mountings for a quick-firing gun, and also for discharging torpedoes. One of Messrs. Yarrow's petroleum launches will also be carried. The "Chiyoda" will, like all modern warships, be lighted throughout by electricity, and will be fitted with all the improvements which the experience of the Japanese officials and of the builders has been able to suggest. She may, therefore, be expected to prove a most valuable addition to the Japanese navy.

The "Chiyoda" is lighted throughout by electricity by Messrs. Mavor & Coulson, Glasgow. The plant is in duplicate. Willans' compound engines are mounted on the same bed-plates with and coupled direct to Siemens' dynamos. The whole work is being carried out to the same system as that adopted by the British Admiralty. The installation consist of about 300 lamps, including thirty 50 c.-p. lamps in special fittings for lighting the coal bunkers. Three projectors will be fitted on board.

H.M. GUNBOAT "MOSQUITO."

IN our impression of the 16th ult. we referred at some length to two gunboats recently built by Messrs. Yarrow & Co., of Poplar, named the "Mosquito" and the "Herald." As we explained at the time, these boats were constructed and made ready for service in an unusually short period of time. The illustration we give above represents the "Mosquito," which, like her sister boat the "Herald," is 77ft. in length by 18ft. beam, and has a draught of 18in. when under steam. It will be remembered that Messrs. Yarrow guaranteed that the vessel should be capable of being put together and got under steam in less than twenty-four hours. As a matter of fact, some experimental trials have proved that she can be put together in so remarkably short a time as six hours and forty-five minutes.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week.

All accounts are payable to GEO. CAWLEY, *358, Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 309, Strand, London, W.C.*

Industries:

FRIDAY, 6TH JUNE, 1890.

THE COMMUNICATION BETWEEN FRANCE AND ENGLAND.

THREE distinct schemes may now be said to be claimants for the approval of the British public with a view to getting rid of the passage by water across the Channel. The first of these, and the one that has heretofore filled the largest amount of space in the popular mind, is the Watkin tunnel; but the Schneider and Hersent proposal to throw a bridge over the "silver streak" has many friends, and its sponsors are still working diligently with a view to having it taken up; while a third scheme has, within the last few days, been prominently brought forward, the *raison d'être* of which is the combination of bridge and tunnel, by throwing a pier or viaduct out into the Channel on both sides for some half a mile, and then lowering the train by a suitable lift into a tunnel or tube, which will complete the journey until the corresponding viaduct or pier is reached at the other side. This latter scheme is, however, hardly likely to recommend itself to the travelling public, inasmuch as there would be considerable trepidation, if not considerable risk, about the working of a lift in the middle of the sea. The bridge scheme retains the chief place in the affections of Frenchmen and of manufacturers, seeing that it would be open to sunlight and would involve the use of over a million tons of metal. The Yankees have done some big things in bridge building, but they would be the first to acknowledge that this bridge, if carried out, would undoubtedly "lick creation." The proposed undertaking is interesting, alike from an engineering, a political, and a financial point of view, and as such may be shortly examined at this time when the Channel tunnel scheme has been revived by Sir E. Watkin and his friends, and when interested parties are making attempts to secure concessions from the State, both in France and in England, with a view to the bridge being carried out.

The more obvious and important advantages claimed for the proposed bridge are: (1) That it would shorten the time of the journey between London and Paris; (2) that it would obviate changing places and breaking bulk, which is now inevitable in the traffic between England and the Continent; and (3) that it would promote the intercourse of England and the Continent for these and other reasons, of which the avoidance of the potent evil of sea sickness is not the least important. The countervailing arguments are (1) that the bridge would involve an outlay that would be far from commensurate with its real utility, and (2) that it would get rid of the insularity, and consequent security, which, as a "sea-girt isle," we now enjoy. It is also objected that the bridge would be a serious obstruction and danger to navigation, but this fear may turn out to be largely groundless. The whole of the piers supporting the bridge would only occupy a little over one-twelfth of the section of the Channel, and some of the spans proposed are to be from 1,500ft. to 1,600ft. wide, which would be sufficient to admit of the easy passage of a ship of the largest dimensions. It may be observed that although no engineer has declared that the undertaking is impossible, all are ready to maintain that not only would it be the most gigantic undertaking of its kind ever attempted, but it would be an enterprise into which many new conditions would be introduced. It is not alone the great length of the bridge—although a bridge upwards of twenty miles in length would, of course, be unique—but the physical conditions under which the work would have to be carried on would involve much strain, and perhaps difficulty. The greatest depth at which the work would have to be carried on would be about 160ft., midway across the Channel. In the sinking of the caissons, and the building of the foundations, it would be necessary to send workmen down to this depth. However, as the average depth would not be more than 75ft. to 100ft., the probability is that engineering resources would provide the needful means for dealing with the exceptional depth in mid-channel. There are, of course, many other engineering problems of great interest and importance concerned in the scheme, such as the floating of the caissons into position, the building up of the piers and the building out of the cantilevers, the housing and protection of the workmen employed, the wind pressures to be provided for, &c. Most of these points have been dealt with in an interesting paper which the chief promoters and engineers of the project submitted to the Paris meeting of the Iron and Steel Institute in September last, and which has since then been the subject of a good deal of controversy in engineering and military circles, both at home and abroad.

It has been asserted by the promoters of the tunnel that their project is much more feasible and likely to be regarded with favour than the bridge, because it is so much less expensive. There is no doubt that in mere first cost the tunnel would be less costly, assuming always that no unforeseen accidents happened in the course of the undertaking. This latter proviso is one that cannot be disregarded in any estimate of the merits of the two schemes, inasmuch as there is always the possibility that unexpected fissures might cause the works to be suspended. But even if the tunnel were to bes uccessfully completed at a total cost of eight to ten millions, which is the amount that has been calculated by experts—allowing for no contingencies, however—the cost of the work would not stop there. The military and naval authorities who have considered the question have expressed the belief that a tunnel would render necessary a permanent addition of some 8,000 men to the garrison at Dover. Now the British army costs, all round, over £100 per man, and if this average were applied to this estimated addition to the force required to protect our shores, it would mean an annual expenditure of £800,000, which, capitalised at only 3 per cent., would mean an addition of over twenty-six millions sterling to the real cost of the tunnel. Besides this, the tunnel would always be regarded with disfavour by the public, on the ground that it would be somewhat difficult to know what is going on inside. The workings might be flooded, or an invading army might be in possession of the structure, before any warning could be communicated; whereas it is always possible to see what is going on if a bridge is erected. Of course, the bridge, while it would require some modification of the existing military situation at Dover, and probably, also, an increase of the garrison there to some extent, would be more easily disabled, so to speak, than a tunnel. There are many simple expedients available for the demolition of a bridge, either partly or wholly, that would not be equally at command for a tunnel.

Digitized by Google

The scheme for the construction of a bridge across the English Channel could hardly be possessed of more influential sponsors. The foundations have been the subject of a most careful and elaborate inquiry by M. Hersent, a distinguished French engineer. The plans for the superstructure have been made the subject of an equally masterly and comprehensive inquiry by Messrs. Schneider & Co., the proprietors of the great ironworks of Creusot. These gentlemen have had the efficient and cordial co-operation of Sir John Fowler and Sir Benjamin Baker, the engineers of the Forth Bridge. Finally, the French banking establishments have intimated their readiness to supply the requisite funds, provided that all the national and international guarantees are satisfactory. This being the position of affairs, the future development of this vast scheme would appear to be dependent on two considerations—the first, that of whether the consent of the maritime powers and interests of the world, including the special consent of England in respect of her paramount interest in the problem, can be obtained; the second, that of whether the bridge, if constructed, would be likely to prove the desideratum which its promoters expect and promise, and the financial success which the shareholders are entitled to look for. As regards the first of these questions, it will be at once apparent that the maritime questions involved, if they do not concern England and France alone, certainly do affect these countries to an infinitely larger extent than any other. Unitedly, these two countries possess nearly three-fourths of the effective ocean-carrying tonnage of the world. The remaining fourth is largely owned by Germany, Holland, and Italy, and to a limited extent by the United States. Scandinavia has also a considerable shipping tonnage, but a great deal of it never comes into the English Channel. The consent of England and France once obtained, it appears unlikely, having regard to the facts just stated, that any of the other maritime countries would have much effective opposition to offer.

The question of whether the bridge, if constructed, would turn out a remunerative undertaking for its proprietors is one that may now be considered. Most of the traffic, other than passenger, at present carried between England and France, is carried by coasters that usually accept low rates of freight. With these the railway could not for a moment compete as regards heavy traffic, or traffic that was not required to be delivered quickly. The cost of ocean transport is never less than four or five times, and is often twenty or thirty times, under that of transport by land. All *petite vitesse* traffic would, therefore, continue to use the sea instead of the railway; but there is a certain amount of *grande vitesse* traffic that would be likely to pass *viâ* the bridge, such as fruit and flowers from the Riviera and Southern France, and fish from Billingsgate for the supply of Paris, &c. This traffic could usually afford to pay a high rate of freight, and would, no doubt, be charged accordingly. There would, however, be only a limited traffic of this description, and the estimate of over nine millions of tons, which has recently been put forward, appears to be altogether unreasonable, unless, indeed, the railways undertook to carry almost as cheaply as the Channel coasters. On the other hand, there would be practically the whole of the passengers for Paris and the localities or countries that are usually reached through that capital, as well as, in all probability, a large part of the passenger traffic that now proceeds from our shores to other Continental ports. What this traffic would amount to in the aggregate it is not easy to say. The traffic to Paris may be taken at some half a million passengers a year, and probably all the other ports, taken together, would represent half a million more. These would, of course, contribute to the bridge in both directions, and if the special proportion of the charge for the journey assignable to the bridge were fixed at 15s. each way, the annual proceeds from passenger traffic would amount to about a million and a half, or, say, sufficient to pay a 5 per cent. dividend on a capital of thirty millions. But the estimate of the cost of the bridge put forward by its promoters is 34½ millions, and some engineers of distinction declare that it is likely to cost much more. Estimates are, as is well known, generally exceeded by results, being founded on the generally incorrect assumption that no serious casualties will occur, which could never apply to such an undertaking as this.

It would be difficult to frame even an estimate of the cost of maintenance of such a structure, but it must be considerable. As regards the income to be expected from merchandise traffic, considering that sea freights are so low, it is not likely to be very much. The main source of income must always be passenger traffic, and that traffic would require to be stimulated very much indeed before it yielded such a rate of dividend upon the enormous amount of the investment as would be satisfactory. Probably, however, the income would be an increasing one, and if the bridge did not cost much in excess of the estimated expenditure, the dividend would come to be a fairly good one.

ENGINEERING IN ITALY.

Mr. M. Yeats Brown, British Consul at Genoa, yearly sends home, perhaps, the most interesting report to engineers of any which come to the Foreign Office. His last is no exception to the rule, and we take from it some interesting information. It will be remembered that some time ago the Italian Government took steps to foster the engineering industries of the country, and foundries and metal works have consequently greatly increased in number in the Genoa district. The imports of metals, which might be expected to have largely advanced in consequence, are, however, very little different from previous years, though machinery has risen from £272,372 in 1887 to £488,640 in 1889. The import list is deceptive as regards raw materials, as a good deal comes overland. The machinery is chiefly plant for the foundries and engineering works, which will now compete with us. Some of the machinery consists of pieces of marine and other engines which these works have orders for, but which they are not yet in a position to make on their own premises. The greater part of the import was from this country. Some of the establishments have been getting steel castings and shafting from Germany, but many prefer to pay higher rates for English materials of reliable quality. Steel boiler plates of the best quality are obtained at the cheapest rate from Glasgow, but it is stated that the contracts for the heavy shell plates for boilers for the Government ships are to be given to the Terni Works, which were described in *Industries*, Vol. II., page 553, and those that require to be flanged or worked are to be ordered from Germany. Light boiler plates and ship plates are now made extensively by Messrs. Raggio and others, and thin steel plates are also made at Sestri and at Rivarolo, where an English manager is said to turn out good work for Messrs. Dufour & Co. Works for making Dick's delta metal have been erected at Cornigliano, and the owners have contracted to supply propellers for the "Liguria" and "Marco Polo" men-of-war. Galvanised iron roofing is now made at Sestri, and iron and steel wire in Turin. At Milan extensive plant has been put down for the manufacture of steel castings. Work is to be commenced shortly, and low rates are to be quoted to establish a connection. Anchors and chains have been largely imported; these come entirely from England. The imports of yellow metal are constantly declining. Tinplates have fallen off owing to large stocks in hand, but prospects of an increase are favourable. A company has been started to manufacture tinplates at Brescia. The iron works of the district have been in active work throughout the past year, and have considerable orders on hand. Messrs. Ansaldo & Co. turned out forty locomotives at Sampierdarena, besides several sets of small marine engines and the 20,000 h.p. main engines for the ironclad "Sicilia," which is being built at Venice. They have also in hand the engines for three large and four small Government vessels, three sets for the Navigazione Generale Company, and two for vessels on their stocks at Sestri. It is not mentioned whether they are of triple or quadruple expansion. They launched last year at Sestri two steel sailing ships (one of which, the "Catterina Accame," was the first steel ship built in Italy), besides several steel pinnaces for the Government, a floating crane of 120 tons for Genoa, and other important work. They have now a large number of vessels on the stocks. Messrs. Odero & Co., of Sestri, turned out three torpedo boats, four barges, and twenty-three sets of launch engines for the Government, and eight engines for mills, varying from 20 to 100 h.p. They are also well supplied with work for the current year. The great works at Savona, known as Tardy, Benecke, & Co., are now worked with German capital and are under German management. They are chiefly employed in making steel rails, but also manufacture heavy ship plates. In addition to these great works, Messrs. Cravero & Co., Balleydier & Co., Wilson & Maclaren, Dufour & Co., and others have all been busy. The Consul states that, as long as the high tariff and premiums on shipbuilding give them such ample protection, they will be enabled to compete against our cheaper prime materials and our greater experience. All other Italian industries have been eclipsed by the remarkable development of metal works and engineering establishments. At San Remo schemes are on foot for lighting the town electrically; one offer has been received from an English firm. The Pertusola lead and iron works are increasing their business rapidly, and they are extending their shipbuilding works under the direction of an English and Italian engineer. The submarine cable manufactory of Messrs. Pirelli & Co. was last year almost at a standstill after two years of great activity. A contract with the Italian Government is, however, being negotiated. Messrs. Buffico & Co.'s ironworks at Spezia have been active. The works of Messrs. Larini, Nathan, & Co. are steadily increasing their business in connection with the Italian Royal Navy and Royal Engineers. The Spezia branch of this Milanese engineering establishment is under the supervision of Mr. Nathan, the English partner, and they are prepared to carry out all orders for dock gates, pontoons, dredgers, boilers, bridge work, portable iron houses, and waterworks. The castings are made at the Milan works, where a small steel foundry has been started. It will be seen from this summary that a flourishing state of affairs exists in the Italian engineering trade, the only exception being the one firm which is dependent upon exceptional circumstances.

OUR TREATIES WITH JAPAN.

We have often referred to this subject, because we think it highly important that official neglect and red tapeism should not further be allowed to strain our relations with Japan.

The *Times* of Friday last published a very interesting letter from its Tokio correspondent, in which he says:—"An event of great importance has just occurred in Japan. On Monday, April 21st, the new Code of Civil Procedure and the first portion of the Civil Code were promulgated. They will be speedily followed by the remainder of the Civil Code and by the Commercial Code. These documents represent the outcome of fifteen years' labour by foreign and Japanese legal experts. They embody the best principles of Western jurisprudence, modified only so far as to suit Japanese conditions. Already the new Criminal Code, which went into force in 1881, has received the approval of eminent European jurists, and there can be no doubt that the Civil Codes just promulgated will also be found satisfactory. Now, therefore, Japan possesses a body of civil and criminal laws which will bear comparison with those of any country in the world. Moreover, just two months ago there was promulgated another ordinance scarcely less important, entitled the 'Law of the Constitution of the Courts of Justice.' This law, the carrying out of which involves a heavy expenditure, completely reorganises the Courts of justice throughout the Empire, and may be said to have secured the endorsement of Western Powers, for the prospect of its imminent enactment was one of the practical guarantees regarded with satisfaction by the foreign negotiators in the treaty revision conferences. With laws fully up to the standard of Western requirements, with Courts organised on an efficient basis, with police of proved competence, and with a prison system which has been favourably described by competent observers, it must be conceded that no substantial barrier stands any longer between Japan and the recovery of her judicial autonomy; or, in other words, between her present semi-isolation and the complete freedom of foreign intercourse which she desires to substitute for it."

After fully explaining the action which has been taken by the Japanese, this correspondent concludes as follows:—"The result, briefly stated, is that the Japanese Government and people are now fully sensible of the paramount necessity of concluding a treaty with England. They see that, whatever may be the goodwill of other Powers, the key of the situation lies ultimately in Great Britain's hand as surely as it lay there twenty years ago. In the negotiations now resumed Japan's whole energy will be directed to securing British acquiescence, and it is not too much to predict that if she succeeds England's influence and prestige in Japan will recover all their lost ground, and stand higher than they ever stood before. The question for Lord Salisbury to consider is whether guarantees, of

Digitized by Google

which one never had any real value, and the other is already fulfilled, should be suffered to stand between England and Japan's friendship, and between the present commercial restrictions imposed on British subjects in Japan and the complete freedom offered by the new treaty. No sensible Englishman cares two straws whether the guarantee about foreign judges remains or disappears, while to Japan its absence means national rejoicing, its presence national umbrage and discontent. One can scarcely exaggerate the effect that will be produced if, in the sequel of all this agitation and perplexity, England comes forward and proves that, so far from ignoring or opposing Japan's claims, she, and she alone, is prepared and competent to secure their universal recognition. It does not often happen that so large a reward awaits such an easy exercise of statesmanship."

THE RATING OF MACHINERY BILL.

In writing of this Bill on a previous occasion (see *Industries* of the 13th November, 1889), we considered its general principles, and the arguments which were adduced in support of it, so that we need not again enter on these. The Bill has now been before Parliament for a considerable time, and in previous sessions it has failed to pass, owing chiefly to the pressure of other business. It was reintroduced early this session, and was read a second time on the 16th of April. Anyone who reads the speeches which were made on that occasion will be forced to the conclusion that the difficulty which has arisen in the matter is really a revival of the old one between the landed and manufacturing interests, a difficulty which has done much to influence British legislation in many ways, as is well known to every student of economic and social science. The problem now before the legislature is to decide fairly between these two interests, and at the same time remove the uncertainty which prevails regarding the actual state of the law, and the want of uniformity in different parts of the kingdom. The interpretation of the law, as at present existing, is open to various readings, or at least various meanings have been given to it, which have led to great anomalies in practice. In Scotland the engines, boilers, and main gearing alone are taxed, and the machinery and implements of trade exempted, and the Court of Session has decided that only such machinery as would go to the landlord at the termination of his lease could be rated.

The Committee stage of the Bill has been put down for the 18th inst., and we are sorry to learn that, notwithstanding the opinion strongly expressed by the House of Commons in its favour at the second reading, a determined attempt is being made by its opponents to defeat it. The chief opposition, as is to be expected, comes from the Rural Boards of Guardians, who look upon manufacturers as fair game. The Bill has not received very cordial support from the legal element in the House, for lawyers do not favour, as a rule, legislation which simplifies legal arrangements or removes doubts as to meaning. Sir Henry James is perhaps the only distinguished lawyer who has given the Bill a cordial support, although at the same time he has not hesitated to criticise and amend some of its provisions. We understand that chiefly through his influence an amendment is to be proposed which will embody the practice in Scotland and exempt all machinery which is used for manufacturing purposes, that is, machinery only fixed to the building with the object of steadying it, and which can be removed without affecting the building and does not require any special arrangements—in other words what may be called the tenant's machinery, as distinguished from the landlord's, will be exempt from rating. A little common sense is all that is required in carrying out such an enactment as this, and we trust that the compromise will be accepted by both sides. This is a question which affects both manufacturers and workmen, and we would strongly advise that all possible influence be brought to bear on members of the House of Commons before the 18th inst., so that the measure may be passed into law.

THE LATE SIR GEORGE BURNS, BART.

The death of Sir George Burns in his ninety-fifth year, which took place on Monday afternoon at Wemyss House, on the Clyde, recalls to our minds the early days of the steam shipping industry, of which he was one of the founders. The son of a well-known Glasgow minister, he was all his life closely associated with Glasgow, and although he retired from active business thirty years ago, he retained his interest in many of the public affairs of the city. Three years ago he assisted at the laying of the memorial stone of the New Barony Church, and gave some interesting reminiscences of the Old Barony, of which his father had been minister for sixty-eight years. Till almost the very end he enjoyed excellent bodily health and unimpared mental vigour. The former was shown by his ability to read and write without spectacles and by his activity, and the latter by the interest he took in scientific and other subjects.

He was born in 1795, and in 1822 he married the eldest daughter of Dr. Cleland, the well-known statistician, by whom he had seven children, only two of whom survive. In 1818, along with his brother James, he commenced business in Glasgow as a general merchant. Some years later he took an interest in some sailing ships, and in 1824 they engaged in steam navigation between Glasgow and Belfast, and shortly after they extended this to the Glasgow and Liverpool trade. In 1830 this was amalgamated with the business of the Messrs. MacIver, of Liverpool, and the trades thus organised included branches between Glasgow and Liverpool, Belfast, Londonderry, Larne, and the West Highlands, all of which are still managed by the Messrs. Burns, except the last, which was disposed of in 1852 to Mr. David Hutcheson. The local arrangements, however, were not sufficient to employ all the energy of Sir George, and he became in 1838 one of the founders of the Cunard Line, which has now attained great magnitude. The capital of the new company was £270,000, and the first contract was with Her Majesty's Government for the conveyance of mails once a fortnight between Liverpool and Halifax and Boston. Gradually the other shareholders were bought out, and the whole concern became exclusively vested in the three families of Cunard, Burns, and MacIver, until it was converted into a limited liability concern a few years ago. The Glasgow business, however, has always been conducted under the names of G. and J. Burns.

Letters to the Editor.

THE LANE FOX PATENTS.

To the Editor of "Industries."

Sir,—As some misapprehension appears to exist in the mind of the public as to these patents, we wish to point out that they are at present held by the Lane Fox Electrical Company, Limited, subject to licences granted to the Brush Electrical Engineering Company (as successors of the Anglo-American Brush Electric Light Corporation), the Edison Swan United Company, and certain other persons abroad.

In the case of one patent, No. 3988** of 1878, for distribution, Messrs. Crompton & Co. and the Swan United Company have obtained an exemption from proceedings for infringement of the patents prior to December, 1882.

The Lane Fox Electrical Company, Limited, has been formed not merely, as has been alleged, to collect royalties; but to carry on a general electrical and incandescent lamp manufacturing business. If the company is fairly met in the question of royalties, but a small charge will be imposed, and it is anticipated that when the question is more fully understood, the reasonableness of the company's charges will be appreciated by the industry.

It should be borne in mind that the Lane Fox patents are in no way invalidated by the long period during which they have been, or appear to have been, in suspense; nor, on the other hand, has that suspense been the fault of Mr. Lane Fox, or designed by him with a view of entrapping companies into their use.

At an early period the Lane Fox patents were disposed of by Mr. Lane Fox, to be worked with other patents, to the British Electric Light Company, Limited, and subsequently to the Anglo-American Brush Electric Light Corporation. Those who are conversant with the early history of electric lighting will know that until recently the principles of incandescent electric lighting were not generally understood, and though Mr. Lane Fox himself well knew the value of his patents, they were not properly appreciated by the companies who held them, and were mixed up and entangled with the claims of other patents held by the same companies for other and competing objects.

In illustration of the general contemporary ignorance of the principles now stated to be obvious, it may be mentioned that when first enunciated by Mr. Lane Fox they were received with ridicule and decried as impracticable, and that such staunch supporters of the system as Messrs. R. E. B. Crompton and W. H. Preece were at first opposed to them; even so great an authority as Sir William Thompson had, for a time, his doubts as to their theoretical soundness.

This opportunity may be taken to correct an impression which, to our great surprise, appears to prevail—namely, that Mr. Lane Fox confined himself, some twelve years ago, to shadowing forth the bare outlines of a scheme the essential details of which were laboriously worked out by others. This is not true. Not only were the principles of incandescent electric lighting distinctly enunciated by Mr. Lane Fox as stated above, but all details necessary to their efficient application were worked out, by him independently, or through his agency, during the years 1878 to 1883. Thus in his hands the system became a thoroughly working system; installations were put up at home and abroad, and when Mr. Lane Fox temporarily abandoned electric work at the end of 1883, his system, which was ridiculed as late as 1881, was accepted and largely used.

After many abortive attempts to regain possession of the patents, attempts giving rise to "agreement" after "agreement" (each, as it was subsequently found, adding to, rather than removing the confusion), an agreement was finally come to upon the conclusion of the recent litigation between the Anglo-American Brush Electric Light Corporation and the Edison Swan United Company, Limited. By this agreement, dated 3rd December, 1889, each of the two litigating companies obtained a licence to use the patents in the future, and an indemnity in respect of the past; but subject thereto, and to certain licences affecting the foreign patents, all the patents were assigned absolutely to Mr. Lane Fox.

In February of this year the Lane Fox Electric Company, Limited, was formed to carry out the long-postponed designs of Mr. Lane Fox, and to vindicate his position as the inventor of the true principles of incandescent electric lighting. The company, however, do not propose to charge vindictive royalties, or in any way to attempt to impede the progress already made, even by the unauthorised use of the Lane Fox patents.

Many times in the course of his prolonged negotiations with the Anglo-American Brush Electric Light Corporation Mr. Lane Fox was invited by competent financiers to join in the formation of a "ring" to control to their own exclusive advantage the electrical industry. Mr. Lane Fox declined. He wished to liberate and not to strangle the industry. Such still is his wish; and the wish of the Lane Fox Electrical Company is the same; but as true liberty consists in justice, and not in injustice, the company will vindicate the patents, and insist upon the payment of royalties in respect of them.

In pursuance of this purpose the company have formulated proposals, the terms of which will in due course be advertised; the pith of these proposals being that if those now using the patents will accept the proposed terms, or such modification of them as may be agreed upon by the middle of June next, no royalties will be claimed for the use of the patents prior to the 31st December, 1889.

It is confidently hoped that the companies, and the electrical industry generally, will see the fairness and reasonableness of the terms proposed, and will co-operate in giving Mr. Lane Fox the position he can fairly claim in the electrical world.

Yours, &c.,
C. A. Stephenson,
Managing Director Lane Fox Electrical Company, Limited.

66, Victoria Street, London, S.W.,
31st May, 1890.

A LETTER EXPRESS.

To the Editor of "Industries."

Sir,—I have the honour to hold a memorial which is about to be forwarded to the Postmaster-General asking for the establishment in this country of a "Letter Express." This memorial already includes the signatures of the Lord Mayor of London (Sir Henry Isaacs), Lord Randolph Churchill, Cardinal Manning, the Bishop of London, Lord Wolseley, and Sir John Lubbock (Chairman of the London Chamber of Commerce).

Will you kindly permit me, through your columns, to invite the opinion on the subject of mayors of towns, members of Parliament, heads of commercial corporations, and of the public generally (the opinions of the Press also would be most valuable), so that the whole may be transmitted, with the memorial, to Mr. Raikes.

Yours, &c.,
Francis George Heath.

Underwood, Kew Gardens,
3rd June, 1890.

The following is a copy of the memorial:—

"To the Right Honourable Henry Cecil Raikes, M.P.,
Her Majesty's Postmaster-General.

"Sir,

"We the undersigned, expressing, as we believe, the opinions of a very large number of persons, beg to call your especial attention to the importance of establishing a 'Letter Express' as an adjunct to the service of the Post Office in this country.

"Amidst the great mass of letters hourly passing through your department, there must be a very considerable number of such importance to the senders that they would gladly pay a small extra fee for immediate delivery. The requirements of such persons are not sufficiently met by the telegraph service, as the cost of a lengthened urgent communication would oftentimes be too great to admit of its being incurred; but as short telegrams would often be sent intimating that express letters were being despatched, the proposed service would tend to augment the telegraph revenue.

"An Express Letter Service of the kind indicated is in successful operation in the United States of America, in Germany, in Belgium, and in Switzerland, and delivery of letters can, we understand, be made within twenty minutes of their reaching the despatching office. As a distinct staff is employed for the work, it is performed without any detriment to the ordinary deliveries.

"If a charge for express delivery of, say, threepence, were made upon each letter, and prepaid by the sender, we believe it would prove to be a source of very great benefit to the general public.

"Trusting that your earnest and immediate attention may be given to this matter,

"We beg to subscribe ourselves, Sir,

"Your obedient servants,

"Henry E. Card. Manning.
"Henry A. Isaacs (Lord Mayor).
"Randolph S. Churchill.
&c. &c.

PIECE WORK.

To the Editor of "Industries."

Sir,—Your leading article of the 16th ult., in which you asked the question, "Can an improved education prevent strikes?" has raised a discussion on the subject of piece work, which, however, appears to be rather one-sided. As a former mechanic I should like to state the opinions I have formed on the subject, as the result both of personal experience and observation. With a conscientious employer piece work is no doubt the fairest method of payment, but there are few men able to withstand temptation when their financial interests are directly opposed to their duties, and the consequence is that piece work in almost all cases becomes mere task work. The workmen at first put all their energy into their work, and continue for some time at a pressure which would soon kill them. They realise large wages, and thus attract competitors, and the employers take the opportunity of lowering prices. A few months of over-exertion reduce the strength of the work-

Digitized by Google

men, while the increasing competition brings down wages almost to the limit of subsistence. Moreover, the system tends to engender a selfishness which prevents apprentices being taught the elements of their trade, and their time is wasted on unskilled work and in carrying messages, and their five years' apprenticeship only results in turning them out handy labourers. This I believe to be the cause of the recent great cry for technical education. If the masters and the men did their duty to the apprentices, that cry would seldom be heard.

Your question, "Can an improved education prevent strikes?" must of course be answered in the affirmative, if we understand education in the proper sense of the term—education both of masters and men, not only in the technical details of their work, but also in their duties to each other—in short, education in "honesty." When we have that, the questions of piece work and day work will settle themselves, and both parties will see that their best interests are bound up together, and can only be advanced by a hearty co-operation which will make strikes impossible.

Yours, &c.,
Glasgow, 2nd June, 1890. A Former Mechanic.

"CAN AN IMPROVED EDUCATION PREVENT STRIKES?"

To the Editor of "Industries."

Sir,—I notice in your issue of the 23rd ult. a letter from "J. W. D.," who answers the above question, raised in your recent leading article, in the affirmative.

If I may venture an opinion on the subject, I would say that undoubtedly a better education would tend to prevent *unreasonable* strikes, but I do not consider that it would either do away with or even lessen the *genuine* strikes, by which I mean the strikes which emanate from the men employed, and where there is a real grievance. I do not think that anything will do away with these, as there will always be unreasonable and unjust employers, and, under such circumstances, the strike seems to me to be the natural, and, perhaps, the proper, check against oppression, deplorable as its results may be.

But it is rare nowadays for us to be treated to a genuine strike. As a rule now, men are "drawn out" without being consulted in the matter, and often quite against their wishes and interests. They do not know what their grievance is, nor whether they have got one. Nor have they the least idea what they are to expect from striking. In such "strikes" as these a better education would tend perhaps to make the men discriminate a little more between the men that have their interests at heart and those that have not, and to insist on the former being placed at the head of their unions.

It has always been my endeavour, when I have had occasion to write on the labour question, to point out that the self-interested and semi-educated men, and the well-meaning fanatics who, as a rule, at present "run" the unions, hold a power which they use dead against the interests of the working man. I think that the only way to effectually protect the working man from his union leaders, and so bring strikes down to their legitimate bounds, would be for legislation to make the trades unions responsible to the law for the fulfilment of all contracts they may enter into with their members or with anybody else. Till this is done they will never know the real wishes of the working man, and strikes alike against the interests of man and master will continue to take place.

The working man should be the master of his union officers. At present he is their slave, and one who sees no probability of freedom.

Yours, &c.,
South Kensington, S.W., 4th June, 1890. J. Stafford Ransome.

COMPRESSED AIR CARS.

To the Editor of "Industries."

Sir,—In Gilbert and Sullivan's "H.M.S. Pinafore" the Bo'sun, referring to Dick Deadeye, says, "What's to be done with this here hopeless chap?" After Messrs. Hughes & Lancaster's last letter I must admit that I similarly wonder what is to be done with them. They either do not understand plain English, or go out of the way to misinterpret it, for they utterly pervert what I have written in previous letters.

It is evidently little use, under such circumstances, to repeat what I actually said. I may mention, however, that I am quite aware that most of the American lines are run on the overhead wire system. I also know that Mr. Reckenzaun has got accumulator cars working successfully in Philadelphia. I also note in your current issue that Mr. Jarman's company are going to run accumulator cars in the south of London at 4½d. or under.

I am always pleased to hear of briskness of trade, and am therefore glad that Messrs. Hughes & Lancaster are so exceedingly busy. When they have fitted up a line on a working basis, and find it run economically, I hope they will find sufficient time to give a record in your columns.

Yours, &c.,
Portsmouth, 2nd June, 1890. Car.

[This correspondence must now cease.—Ed. *Industries.*]

BRITISH MANUFACTURES ON THE CONTINENT.

To the Editor of "Industries."

Sir,—The fact cannot be ignored that with some of our staple productions there is not that success attending their exploitation that might be naturally expected from their intrinsic merits in markets quite close to our own shores. In far off directions like Japan, Australia, South America, &c., we hold the principal position against all comers in nearly every department. With many of the large consuming countries of the Continent, however, the Belgians, the Swiss, and the Swedes surpass us in railway plant, fixed engines, steamers, and certain other details. Neither of these items can be built cheaper elsewhere, nor can we look to charges of exportation for the difference, and duties would be the same in any given case. Yet that Swedish steamers go largely to Russia, and Belgian machines to Germany, is common knowledge. In short, the Continent is almost like one vast compact country in itself, where a great interchange of manufactured goods takes place. Germany and France are celebrated for war material, and generally may be said to supply the bulk of these plants to the other Powers of Europe, including guns, torpedoes, and torpedo *boats*; Switzerland is celebrated for its engines, both locomotive and fixed; while Belgium has a notoriety in the way of steel goods, and Holland and Sweden do well with special classes of steamers.

What accounts, then, for the backwardness on the part of British manufacturers in these fields of trade? Is it the lack of that enterprise which has hitherto characterised us, to which we can attribute any failures to compete with our neighbours on their own ground? Probably our very insular position, the cause of our success as colonisers, is the answer to the above question.

The typical Englishman is not at home with the suave manners he finds, say, in Russia. The customs outside his own islands are very different to what he is accustomed to, whereas amongst all Continental peoples there is a similarity of style. Can nothing, therefore, be done to break down the barrier standing between us and these markets? Are we to believe that for ever these gates are closed to our trade? Here it must be allowed that where commerce is to be carried out trained hands are wanted for doing it. The simple fact that an article is the best suited for its particular purpose is not enough. Intelligent men, acting as go-betweens from the manufacturers to the consumers, are absolutely necessary. These England does not possess in sufficient numbers as far as the Continent is concerned. A very wide field is opened up by this remark. It virtually means that, after the vast sums spent in education, we still lack certain elements.

I do not suggest that every youth should be trained to speak French, German, Russian, &c. Certainly, however, it would be in the interest of manufacturers to initiate schools of languages in every district, so that those who had any aptitude might obtain scholarships, and thus be met half-way in their studies. An aspirant, as it is now, meets with too many difficulties in the pursuit of what he desires. We have institutions for everything in these days, but this question of thorough and systematic teaching in living languages still remains to be solved.

The ever-ready Teuton is ahead of us with the College for Oriental Languages in Berlin. It behoves us, therefore, to bestir ourselves in this matter, though probably, with native races, other points in our system outweigh any disabilities in this particular.

Chambers of Commerce have been very active in recent years, but laurels are yet waiting to be grasped by enterprising bodies who have our industrial supremacy at heart. In the direction of languages lies, in my opinion, the kernel of our future position in the world's trade. Given an army of young men, capable of speaking two or three foreign languages, the quality of our wares will do the rest.

"Trade follows the flag" is a motto well known to Englishmen. On the Continent, however, we may justly say that to make known the various classes of British manufactures requires an exponent of intelligence equal to what is found on the spot. Any expenditure would be well laid out in seeing that we were not behindhand in this department. Moreover, it is becoming an ever-increasing question whether we are not already suffering in over-sea markets by our extreme apathy in this matter of languages, for the population embraces a larger proportion than ever of Germans in one colony, Italians in another direction, and so on through the list of the emigrating nations. Many of these traders in other lands require to be communicated with in their own tongue. Until, therefore, this link in the great chain of our commercial relations has been forged, we cannot be said as a nation to have done all that might be expected from us as a practical people.

Yours, &c.,
London, 3rd June, 1890. Trader.

INSULATION RESISTANCES OF CABLES.

(*From an American Correspondent.*)

On Saturday, the 24th of May, a representative of the *New York Electrical Review* visited an electric light installation by the United Electric Improvement Company at their works in Gloucester, New Jersey; and also witnessed some interesting tests of the insulation of the underground main conductor, which is a No. 0 gauge drawn into a wrought-iron pipe buried some 2ft. below the surface of the ground, and insulated by the Brook system, carrying a current of 2,700 volts and 9 amperes, feeding the current to 50 arc lamps. The insulation tests by the ordinary galvanometer method showed something over 1,000 megohm miles, but a more satisfactory test was by a Holtz machine, which produced a spark 6in. in length. This failed to puncture the insulation or affect it in any way.

It is now pretty well known that an insulation which may test very high galvanometrically with the potential of 200 to 500 elements, may, when subjected to the pressure of 2,000 or more volts, be easily broken down or disrupted. Mr. Wm. Maver, Jun., recently stated that a cable measuring 20,000 megohm miles of insulation in the factory, broke down by a dynamo current of 600 volts, after being drawn into a conduit. Drs. Warren de la Rue and Hugo Muller published the following figures as the striking distance between a point and a disc:—0·5in., 11,700 volts; 1in., 23,400 volts; 2in., 46,700 volts; 3in., 70,100 volts; 4in., 93,500 volts; 5in., 116,800 volts; 6in., 140,200 volts; 7in., 163,600 volts; 8in., 186,900 volts; 9in., 210,300 volts; 10in., 233,700 volts; 20in., 467,300 volts; 30in., 701,000 volts; 40in., 734,700 volts; 50in., 1,168,300 volts. It is stated that these experimentors used a battery of eleven thousand cells as a basis for obtaining the foregoing figures.

The Gloucester cable is insulated with a semi-liquid preparation, which is comparatively cheap, and an increase of insulation does not proportionately increase the cost per conductor. There is another feature of this method of insulation. The pipes are laid in the grounds and the conductors drawn in and insulated afterwards. In this respect it differs from all other modes. Cable, insulated in factories, and afterwards coiled, uncoiled, and drawn into conduits, are liable to injury by that operation, especially so if employed for arc-lighting purposes. There were at Gloucester a variety of specimens of arc-lighting cables, the insulation of which was easily punctured by a spark of less than 1in. in length. Many authorities quote dry air as the highest insulating medium, and it is probably correct as tested by ordinary methods, but for high voltages it certainly does not compare with liquids. Bearing upon this point was a statement by Mr. Foudersmith, the electrician of the Pennsylvania Railroad Company, who was present and witnessed these experiments, to the effect that of the fifty-three conductors laid by Mr. Brooks three years since on the Pennsylvania Railway, not one of them had ever been interrupted by atmospheric discharges or any other cause, though lightning was a great source of trouble and interruption to all other kinds of insulation used for underground and river crossings, and that the insulation of this Brooks cable, one and one-third miles in length, was at this day thousands of megohm miles, and as high or higher than when first laid.

RESEARCH COMMITTEE ON MARINE ENGINE TRIALS.*

1. Trial of the S.S. "Fusi Yama."

Steamer.—This steamer was tested as a good example of an ordinary trading vessel working under the usual conditions. She belongs to Messrs. Gellatly, Hankey, Sewell, & Co., to whom the committee are much indebted for giving them every facility for making the experiments. She is a vessel of 214·3ft. in length between perpendiculars, 29·3ft. beam, and 20·5ft. depth. Her registered tonnage is 632 net, and her gross tonnage 994, under deck 899 tons. Her displacement on the day of the trial, when the mean draught was 18ft. 11¾in., was 2,175 tons. The trial was made upon the 14th and 15th November, 1888, on a run from Gravesend to Portland. The ship left Gravesend, where her compasses had been adjusted, about six o'clock on the afternoon of the 14th November, and the trial started at 8.51 p.m. on that evening. It lasted until 11 a.m. on the 15th. The run was continuous, with the exception of stoppages amounting in all to 12 minutes between 3.10 and 3.25 a.m. when landing the pilot off Dover. In addition to this the engines were running slow for about 13 minutes between 3 and 3.30 a.m. The reading of the counter was entered at each change of speed or stoppage during this time.

Engines.—The "Fusi Yama" is fitted with compound surface-condensing engines, made by Mr. Martin Samuelson, of Hull, in the year 1874. They had been thoroughly overhauled by Messrs. Rait & Gardiner, under the superintendence of Mr. Frederick Edwards, immediately before the trial, and were in thoroughly good working order. The cylinders' diameters are 27·35in. and 50·3in., measured from gauges. Their common stroke is 33in. The diameter of both piston-rods is 4·9in. There are no tail rods. The cranks are at right angles, the low-pressure leading. The cylinders are not jacketed. The clearances of the high and low pressure cylinders as measured on the drawings are respectively 7·6 and 5·0 per cent. Each cylinder is provided with a single slide-valve worked by the ordinary link-motion gear. The throttle and stop valves, and the link-motion, were sealed up at starting. The link-motion, however, was opened out a little at 1.24 a.m., and remained in its new position during the rest of the run. The screw propeller is four-bladed, having a diameter of 13ft., and a mean pitch of 16·37ft.

Boilers.—Steam is supplied by one boiler 13ft. 3¾in. mean diameter, 11ft. long, and containing three furnaces. The total grate surface is 52 square feet, and the total heating surface 2,257 square feet, the ratio between the two being 1 to 43·4. The mean diameter of the flues is 2ft. 11½in. The fire-bars are of the ordinary description, and there are 17 bars in the width of each furnace, and therefore 34 in each grate. There are 232 tubes of 3¾in. external diameter, and 7ft. 5in. long between plates, equivalent to a total tube surface of 1,689 square feet, which is 32·5 times the grate surface. The internal diameter of the funnel is 4ft. 6¼in., and its total height is 43ft. 2in. above the centre of the lowest furnace. The total weight of the engines and boiler, including water in condenser pipes and boiler, and all mountings, is about 100 tons. The net volume of the boiler is about 1,681 cubic feet.

Duration of Trial.—The duration of the trial from start to finish was 14 hours 9 minutes. Deducting the 12 minutes of stoppage, the running time was therefore 13 hours 57 minutes, or 837 minutes.

Coal Measurement.—The same method was used for weighing the coal as was employed upon the "Meteor" trial. About 70lb. of coal were weighed in each bucket, and about nine buckets were weighed on to the stoke-hold floor at one time. The trial was started with a clean floor. The time was noted at which each lot of weighed coal was put upon the fire, and no more coal was weighed out until the floor was again clear. The line of coal consumption plots out as shown upon the diagram, Fig. 1. The fires were not cleaned during the run. The ashes were weighed after the trial was over. The coal was West Hartley Tyne coal, costing 15s. 9d. per ton. It was somewhat irregular in quality, but a sample collected at different times during the run, and

* Report prepared by Professor Alexander B.W. Kennedy, F.R.S., Chairman of the Committee for the Institution of Mechanical Engineers, and read at the meeting of the Institution on the 1st ult.

Digitized by Google

afterwards well mixed and pounded, gives the following analysis, which has been made by Mr. J. C. Wilson:—

	Coal as Used.	Dry Coal.
Carbon	70·85 per cent.	77·52 per cent.
Hydrogen	4·71 „ „	5·15 „ „
Moisture	8·60 „ „	0·00 „ „
Ash	5·11 „ „	5·59 „ „
Nitrogen, sulphur, oxygen, &c., by difference	10·73 „ „	11·74 „ „
	100·00	100·00

The calculated calorific value of this fuel as used is 12,760 thermal units per lb., which is equivalent to the evaporation of 13·21lb. of water from and at 212° Fahr. The equivalent carbon value of this fuel as used is 0·878lb. per lb. The total coal used was 13,768lb. in 849 minutes. As, out of the whole time of running, the engines were stopped for 12 minutes, during which period, of course, the fires were more or less damped, it may be taken that the actual time of firing was equivalent to about 840 minutes; but in order not to confuse matters, the boiler time will be taken as equal to the engine time—that is to say, to the time during which the engines were actually running, namely, 837 minutes. The total coal was therefore 16·45lb. per minute, or 987lb. per hour. The weather was fair until reaching Dover, but became very rough during the last part of the trial, which was brought to an end somewhat sooner than was intended, because of the great difficulty of obtaining further accurate measurements. Up to the actual point of ceasing observations, however, the weather did not affect their accuracy, although it rendered difficult the estimation of the water-level in the boiler at the end of the trial. The roughness of the weather at the end of the trial prevented accurate measurements being made as to the amount of clinker obtained from cleaning the fires. The actual amount of ash weighed off from under the grates was only 278lb., or about 2 per cent. of the total weight of the fuel.

Furnace Gases.—The temperature of the chimney gases was observed 15 times during the trial, and its average value was 578° Fahr.; the highest reading being 617°, and the lowest (which was just after starting) 500°. Two samples of furnace gases were collected and analysed; the analyses of these by weight and by volume are given in Table I.

The mean chimney draught, which was measured by a U gauge-glass at the place where the furnace gases were collected, was 0·28in. of water.

Feed-water Measurement.—The feed-water was measured in the same way as for the "Meteor," on its way from the hot-well to the feed-pump of the engine. The tanks used for weighing it (which held about 260lb. each) were placed on the upper engine-room platform; their contents were carefully tested by weighing water into them, and they were at the same time ascertained to be free from any leakage. The necessary correction having been made for the temperature of the feed, the total water used amounted to 109,800lb. (its mean temperature being 129·5° Fahr.), over a total time of 850 minutes. The last feed-tank was emptied at 11·1 a.m., or one minute after the last reading of the counter, so the engine was actually running during 838 minutes of this time, so that the mean consumption of water per minute (engine time) was 131·0lb., or 7,860lb. per hour. The continuous consumption of feed-water is shown in Fig. 1. All the steam made by the boilers went to the main engine, steam being kept up in the donkey boiler for any other purposes that were required.

Power Measurement.—Indicator diagrams were taken at about half-hourly intervals throughout the whole of the trial, 26 sets or 104 cards being taken in all. A pair of Darkes' indicators were used on the high-pressure cylinder with ¼th springs, and a pair of Richards' indicators on the low-pressure cylinder with ¼th springs. The following are the mean effective pressures in the two cylinders in pounds per square inch:—

Cylinder.	Top.	Bottom.	Mean.
High-pressure	31·06	30·41	30·74
Low-pressure	10·43	11·30	10·87

These pressures correspond with the following indicated horse-powers:—

High-pressure cylinder	168·2
Low-pressure cylinder	203·1
Total indicated horse-power	371·3

One set of cards was taken during the time when the engines were slowed down (13 minutes), and the proper allowance has been made for this in the preceding averages. The maximum indicated horse-power given by any one set of cards was 402·2, which occurred at 5·30 a.m., with 57·5 revolutions per minute, and 59lb. of steam. The minimum indicated horse-power by any one set of diagrams at full speed was 313 at 11 p.m., with 53 revolutions per minute, and 49lb. of steam. From the 104 diagrams which were taken during the trial a mean diagram has been plotted for each of the two cylinders, and these are given in Fig. 4. The continuous variations of boiler pressure and cylinder mean effective pressures are shown in Fig. 2; and of horse-powers and speeds in Fig. 3.

Speed.—The counter read 8,507 at 8.51 p.m. when the trial commenced, and 55,033 at 11 a.m. when the trial ended. The total number of revolutions made by the engines was therefore 46,526 in a total running time of 837 minutes, which gives an average rate of 55·59 revolutions per minute. The maximum number of revolutions per minute for any half-hour was 57·5, and the minimum number (except when slowed down) was 53.

Pressures, &c.—The mean barometic pressure during the trial was 30·1in. of mercury, or 14·8lb. per square inch. The mean boiler pressure was 56·84lb. per square inch above the atmosphere, measured on the gauge in the stoke-hold. On the engine-room gauge the mean pressure was 55·2lb. per square inch. It will be seen from the diagram that the pressure was fairly constant, except during about two hours towards the beginning of the run, and during the time when the engines were slowed down. The pressure-gauge in the stoke-hold was read every quarter of an hour during the trial, and the other gauges were read every half-hour alternately with the counter readings, and at the same time as that at which the indicator cards were taken. The mean reading of the vacuum gauge was 25·40in. of mercury, or 12·48lb. per square inch below the atmosphere. The mean initial pressure in the high-pressure cylinder (from measurement of diagrams) was 50·3lb. per square inch above the atmosphere; and the mean back-pressure in the low-pressure cylinder was 10·9lb. per square inch below the atmosphere, which corresponds to an absolute back-pressure of 3·9lb. in the cylinder.

Boiler Efficiencies.—The rate of combustion in the furnaces was 18·98lb. of coal per square foot of grate surface per hour, or 0·437lb. per square foot of total heating surface per hour. The evaporation was at the rate of 7·96lb. of water per lb. of coal. As the feed entered the boiler at a temperature of 129·5° Fahr., and as the temperature corresponding to the mean steam-pressure was 304° Fahr., each lb. of steam must have taken up 1,077 thermal units; so that the equivalent evaporation from and at 212° Fahr. was 8·87lb. of water per lb. of coal, or about 10·10lb. per lb. of carbon-value in fuel. The equivalent amount of heat utilised per lb. of coal was 8,570 thermal units, or, say, 67·2 per cent. of the whole calorific value of the fuel, which percentage, therefore, represents the actual boiler efficiency. The total nominal calorific value of the fuel burnt per minute was 209,900 thermal units. Assuming that the two samples of furnace gases analysed gave a fair average value, it appears that the weight of dry air per lb. of coal was about 22·8lb. The loss of heat in raising the temperature of the furnace gases from 55° Fahr., allowing for the steam due to the combustion of the hydrogen in the fuel, works out to 2,995 thermal units, or 23·5 per cent. of the whole calorific value of the fuel. There was no loss by formation of carbonic oxide. The loss due to evaporation of the moisture in the fuel would be 0·9 per cent. These quantities add up to 91·6 per cent. of the whole heat of combustion, the balance of 8·4 per cent. including all losses by radiation. The weight of water evaporated per square foot of total heating surface was 3·48lb. per hour. The average rate of transmission of heat through the material of the boiler was 3,750 thermal units per square foot of total heating surface per hour.

Coal Consumption.—The total coal burnt—namely, 987lb. per hour—corresponds to 2·66lb. per indicated horse-power per hour. This is equivalent to 2·33lb. of carbon value per indicated horse-power per hour.

MARINE ENGINE TRIALS.

	100·00	100·00	100·0	100·00	100·00	100·00

Digitized by Google

Engine Efficiencies.—The measurement of feed-water shows that the quantity used per indicated horse-power per hour was 21·17lb. per hour. The actual heat received by the feed-water per minute was 141,100 thermal units, or 380 thermal units per indicated horse-power per minute, which is 67·2 per cent. of the whole heat of combustion. The absolute engine efficiency, or ratio of the heat turned into work to the total heat received by the feed-water was 11·25 per cent.

Total Efficiency.—The combined efficiency of the boiler and engines, or the ratio of the heat turned into work to the total heat of combustion of the fuel, was 0 672 × 0·1125, which is equivalent to 7·6 per cent.

Steam from Indicator Diagrams.—The following are the results of measurements made upon all the indicator diagrams taken to ascertain the proportion of steam accounted for by them. The actual weight of feed-water used per revolution was 2·357lb.:—

Proportion of Steam accounted for by Indicator Diagrams.	Lb. per Revolution.	Percentage of Total Feed.	Percentage present in Cylinder as Water.
Steam present in high-pressure cylinder after cut-off, when the pressure was 45·2lb. per square inch above the atmosphere	Lb. 2·08	Per Cent. 88·2	Per Cent. 11·8
Steam present in low-pressure cylinder near end of expansion, when the pressure was 4·8lb. per square inch below the atmosphere	1·66	70·7	29·3

(To be continued.)

THE BOARD OF TRADE AND ELECTRIC LIGHTING.*

The first attempt to deal with the question of electric supply on the part of the Legislature was the Act of 1882. As notice had been given of many private Bills to be brought in to acquire the necessary powers for a general supply, proceeding on very varying lines, it was thought that the time had come for a general Act dealing with the subject. The two principal objects of this Act were: (1) To empower electric supply companies, or persons, or local authorities desirous of undertaking this supply for their own districts, to lay their mains in the public streets, and conduct the business of supply generally in a manner recognised by law; (2) to recover charges for supply made to consumers. At the same time proper regulations and conditions were imposed upon the undertakers to secure the safety of the public and the adequacy of the supply; while the fear of creating a new perpetual monopoly was evidently present in the minds of the framers of the Act. This Act is so familiar that a short sketch of its provisions will be sufficient. It sets out by detailing the various ways in which statutory powers can be obtained. These are: (1) By licence; (2) by Provisional Order; (3) by special Act.

The issue of licences is left entirely in the hands of the Board of Trade, but the consent of every local authority affected must first be obtained. The original period for which a licence is granted must not exceed seven years, but it may be renewed with the like consents. A licence may be for "public purposes" or "private purposes." "Public purposes" only allows supply for electric lighting of streets, public places, buildings, theatres, &c.; while "private purposes" allows general supply, not only for lighting, but for any other purpose, except the transmission of any telegram. The Board of Trade is empowered to make such regulations and conditions in a licence as it may think expedient.

Provisional Orders in this Act may be granted without requiring the previous consent of the local authorities affected, but have no force unless and until confirmed by Act of Parliament. The period of an Order may be limited, or it may be unlimited in duration. There appears to be very generally diffused a mistaken idea on this point. Many people appear to think that a Provisional Order only lasts for 42 years, or 21 years under the old Act. This was stated in the *Times* the other day as a fact It is, however, quite a mistake. The Orders granted by the Board of Trade, and confirmed by Parliament, have hitherto been, without exception, I think, unlimited in duration. There are various provisions for sale or transfer of the undertaking, including, in the case of a company, compulsory sale to the local authority; but these provisions may never be acted upon, and even if they are put in force, do not extinguish the powers granted. Section 6, with respect to regulations, is so important that it will be better to give the exact words—

"6. The undertakers shall be subject to such regulations and conditions as may be inserted in any licence, Order, or special Act affecting their undertaking with regard to the following matters:—(*a*) The limits within which and the conditions under which a supply of electricity is to be compulsory or permissive; (*b*) the securing a regular and efficient supply of electricity; (*c*) the securing the safety of the public from personal injury, or from fire or otherwise; (*d*) the limitation of the prices to be charged in respect of the supply of electricity; (*e*) the authorising inspection and inquiry from time to time by the Board of Trade and the local authority; (*f*) the enforcement of the due performance of the duties of the undertakers in relation to the supply of electricity by the imposition of penalties or otherwise, and the revocation of the licence, Order, or special Act where the undertakers have, in the opinion of the Board of Trade, practically failed to carry the powers granted to them into effect within a reasonable time, or discontinued the exercise of such powers; and (*g*) generally with regard to any other matters in connection with the undertakings. Provided always that the Board of Trade may from time to time make such regulations as they may think expedient for securing the safety of the public from personal injury or from fire or otherwise, and may from time to time amend or repeal any regulations which may be contained in any such licence, Order, or special Act in relation thereto: and any regulations so made or amended by the Board of Trade shall, from and after the date thereof, have the like effect in every respect as though they had been originally inserted in the licence, Order, or special Act authorising the undertaking; and every regulation so repealed shall, from and after the date thereof, be repealed accordingly, but such repeal shall not affect any liability or penalty incurred in respect thereof prior to the date of such repeal, or any proceeding or remedy which might have been had in relation thereto. Any local authority within any part of whose district electricity is authorised to be supplied under any license, Order, or special Act may, in addition to any regulations which may be made under the preceding provisions of this section for securing the safety of the public, from time to time make, rescind, alter, or repeal bye-laws for further securing such safety; and there may be annexed to any breach of such bye-laws such penalties, to be recovered in a summary manner, as they may think necessary: Provided always, that no such bye-laws shall have any force or effect unless and until they have been confirmed by the Board of Trade and published in such manner as the Board of Trade may direct."

The proviso enabling the Board of Trade to make regulations from time to time, and to amend or repeal any regulations, is certainly a wise provision, and it has been largely carried into effect. The power conferred upon the local authority of making bye-laws for further securing the safety of the public should also be noted, and that this may be exercised even where they are themselves the undertakers. In the case of local authorities being undertakers, power is given for them to contract for the execution and maintenance of any works, or for the whole business of supply; but they are forbidden to transfer or divest themselves of any legal powers or liabilities without the consent of the Board of Trade. As regards overhead wires, undertakers must get the express consent of the local authority for their erection along, over, or across any street, and the local authority may remove any electric line placed above ground without such consent, and, even where such consent has been given, a court of summary jurisdiction may order the removal of any electric line, on the ground of public safety. It must be noticed, however, that nothing in this Act empowers any interference on the part of the Board of Trade or any other authority with electric lines erected by persons who are not undertakers. The undertakers are not allowed to prescribe any special form of lamp, or to interfere with the use made by any consumer of the supply given to him; but no consumer is to deal with his supply in such a manner as to unduly or improperly interfere with the supply to other consumers; and any dispute as to this is to be determined by arbitration. There are provisions against undue preference on the part of the undertakers in their supply and charges. I take the meaning of these sections (19 and 20) to be this—that the undertakers may make any agreement as regards price, hours of supply, &c., provided that the price is not in excess of the maximum rates laid down; but that, where they have made any such agreement with any private consumer, any other private consumer may demand a similar agreement, where the conditions are similar; and so in the case of street lighting authorities; but not that a private consumer could demand to be supplied at the same rate as is agreed upon for the street lighting or for lighting a large theatre. Supply may be cut off for neglect of payment of charges due, but only until these charges and any expenses incurred in cutting off the supply are fully paid. Any unlawful and malicious injury of electric lines and works is made a felony, and any person who maliciously or fraudulently abstracts, causes to be wasted or diverted, consumes or uses, electric energy is declared to be guilty of simple larceny—in fact, to have stolen it. The purposes for which the officers of the undertakers may enter premises of consumers are strictly defined, and they have no legal right of entry for any other purpose—*e.g.*, to inspect the electric lines and fittings of the consumer. The Board of Trade has, however, so framed the Orders and Safety Regulations as to make it unlikely that any consumer would refuse entry to a properly authorised agent of the undertakers, if required by them to make an inspection of these electric lines and fittings.

In the section of the Act providing for the protection of the Postmaster-General, it is curious to note that a distance of 10 yards was apparently considered as the outside limit of distance within which a telegraph line might be affected by an electric supply line. The section dealing with compulsory purchase by the local authority after 21 years has been made the scapegoat for the failure of the electric lighting "boom" of 1883. It is questionable, however, whether it had so much effect as is attributed to it in preventing capitalists from coming forward to support electric lighting schemes, and also whether whatever checking influence was really due to it has not in the long run been as beneficial as a nipping frost in early spring in restraining youthful impetuosity. And I may remark that this clause did not excite any serious opposition at the time; in fact, the Bill was sent up from the Commons with a fifteen years limit, and extended in the Lords to twenty-one years, which was considered an ample time even by the persons best qualified to judge, as is amply demonstrated in the minutes of evidence given before the Parliamentary Committee.

In the amending Act of 1888 the first section has two important provisions—"1. Notwithstanding anything in the Electric Lighting Act, 1882, no Provisional Order authorising the supply of electricity by any undertakers within the district of any local authority shall be granted by the Board of Trade except with the consent of such local authority, unless the Board of Trade, in any case in which the consent of such local authority is refused, are of opinion that, having regard to all the circumstances of the case, such consent ought to be dispensed with; and in such case they shall make a special report, stating the grounds upon which they have dispensed with such consent. The grant of authority to any undertakers to supply electricity within any area, whether granted by licence or by means of a Provisional Order, shall not in any way hinder or restrict the granting of a licence or Provisional Order to the local authority, or to any other company or person within the same area." The second section repeals section 27 of the former Act, and substitutes forty-two years for twenty-one, as the time to elapse before compulsory purchase can be enforced. Section 3 gives power to the Board of Trade to vary the terms of compulsory sale in accordance with any agreement between the local authority and the undertakers. Section 4 is very important, as it empowers the Board of Trade to make regulations for the protection of the public safety and of telegraphic and telephonic lines in the case of any electric lines used for the supply of electric energy, however laid or erected, and whether under statutory powers or not. Perhaps I had better give the first part of this section—"4. (1.) Where in any case any electric line or other work may have been laid down or erected in, over, along, across, or under any street, for the purpose of supplying electricity, or may have been laid down or erected in any other position for such purpose in such a manner as not to be entirely enclosed within any building or buildings, or where any electric line or work so laid down or erected may be used for such purpose otherwise than under and subject to the provisions of a license, Order, or special Act, the Board of Trade, if they think fit, may, by notice in writing under the hand of one of the secretaries or assistant secretaries of the Board of Trade, to be served upon the body or person owning or using or entitled to use such electric line or work, require that such electric line or work shall be continued and used only in accordance with such conditions and subject to such regulations for the protection of the public safety and of the electric lines and works of the Postmaster-General, and of other electric lines and works lawfully placed in any position and used for telegraphic communication, as the Board of Trade may by or in pursuance of such notice prescribe; and in case of non-compliance with the said regulations, then the Board of Trade may require such body or person to remove such electric line or work: Provided that nothing in this sub-section shall apply to any electric line or work laid down or erected by any body or person for the supply of electricity generated upon any premises occupied by such body or person to any other part of such premises." Sub-section (2) provides for the Postmaster-General taking action himself in the case of lines not laid under statutory powers, in the event of actual interference with his telegraphic lines, provided that these lines are not already regulated by the Board of Trade. The general purport of the section is to place the responsibility for the proper regulation of electric supply wires generally on the Board of Trade.

We now come to the dealings of the Board of Trade with the subject, and I propose to consider in the first place the various forms of Provisional Orders granted under the general Acts As licences differ very slightly in form from Orders of the same date, it will not be necessary to discuss them. There are up to the present time four forms of Orders, differing materially from each other in important respects, and showing, I consider, progressive improvement in the treatment of the subject as experience was gained. These are—1st, The 1883 form, of which Bradford is, I think, the only one now actually being worked, but some other local authorities are preparing to start under old Orders; 2nd, The Chelsea Order of 1886, and St. Austell Licence of 1885; 3rd, The London Orders of last year, which form, I may point out, is only applicable to metropolitan districts under the London County Council; 4th, The model forms of Orders for this year, which are even now being modified in certain clauses, and will not attain finality until some points have been determined by the action of Parliament. There are slight variations in form among individual Orders, generally due to some local considerations, and in every case there are considerable differences between Orders granted to local authorities and those granted to companies.

The first matter in all the Orders is the interpretation clause. In this, last year an innovation very important to electricians was introduced—viz., the definitions of "energy" and "power"—"The expression 'energy' shall mean electrical energy, and for the purposes of applying the provisions of the principal Act to this Order electrical energy shall be deemed to be an agency within the meaning of electricity as defined in the Electric Lighting Act of 1882." And "the expression 'power' shall mean electrical power, or the rate per unit of time at which energy is supplied." They hang upon the definition of electricity in the principal Act as "electricity, electric current, or any like agency." Rather a general definition, you see. Now the use of the term "energy" has, I consider, materially improved the language of the Orders, both from a scientific and a legal point of view. Under the old forms of Orders the undertakers were authorised to supply "electricity," and continual reference is made to this as the quantity supplied. Now this word has, or had, many meanings, but in this case it could only mean electrical energy. But when we turn to the "Price" clauses we find that energy is expressly mentioned as differing from electricity, and that there, at all events, the latter meant what we now call "electrical quantity." There really was here some confusion of language, distressing to the electrician and opening up grand possibilities of endless talk to lawyers. The proposed amendment was referred to your Council and concurred in by them, and I am glad to notice that the use of the term "electrical energy" is gradually working its way. I am not yet satisfied, however, with our word for what used to be the particular meaning electricity. It is rather absurd to call it "electrical quantity," since so many other things are electrical quantities. I almost think we want a word for this even more urgently than for electrical locomotion, over which so much ingenuity has been lately expended. The worst of it is that, as nobody knows what it is, or to what extent its existence is an objective reality, it is difficult to find an appropriate word. At any rate, it was impossible in the Orders to call it "electricity" any longer, as the Act says that is what is to be supplied; so that we had to define "energy" as what was meant by electricity in the Act, and use "electrical quantity" for the particular meaning for want of a better word. This also necessitated an alteration in the title. There is a slight further alteration in the new model title. As regards the definition of "power," this was necessary to avoid a difficulty in modifying a few clauses in the old Orders which dealt with the maximum current to any consumer to render them applicable to tranformer systems.

The definition of "main" has been materially altered. Thus it used to mean the conductor alone, then a continuous electric line, defined in the Act as follows:—"The expression 'electric line' means a wire or wires, conductor, or other means used for the purpose of conveying, transmitting, or distributing electricity with any casing, coating, covering, tube, pipe, or insu-

* Paper read by Major Cardew before the Institution of Electrical Engineers on the 17th inst.

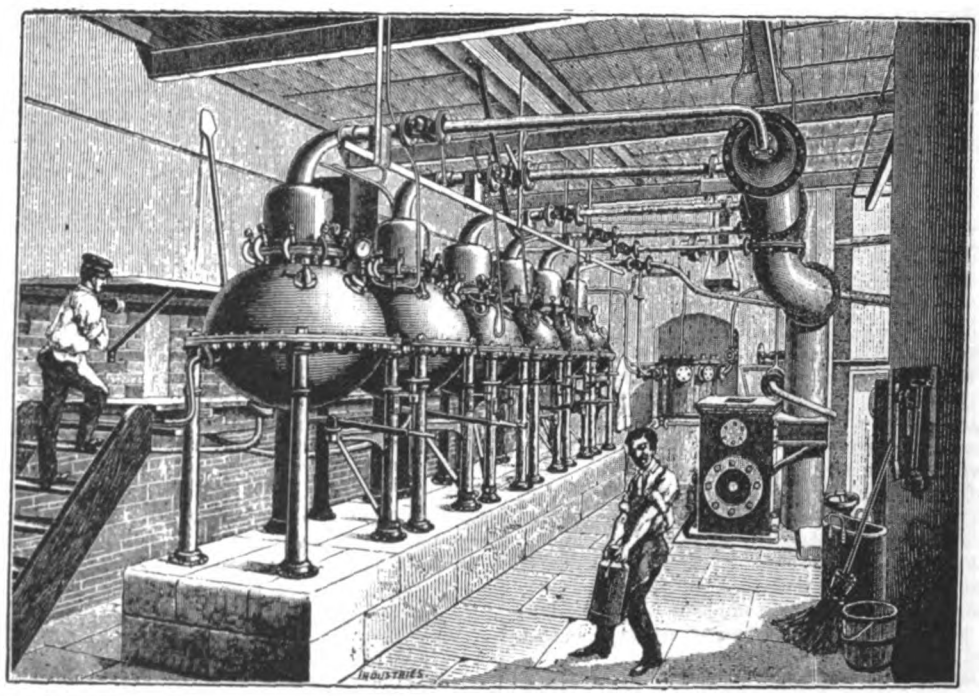
Digitized by Google

lator enclosing, surrounding, or supporting the same, or any part thereof, or any apparatus connected therewith for the purpose of conveying, transmitting, or distributing electricity or electric currents." And, lastly, the word "continuous" has been omitted as unnecessary in the case of transformer systems. The definition of "service line" has been altered in the same way. "Distribution main" has not been altered. It is a very important definition, as follows:—"The expression 'distributing main' shall mean the portion of any main which is used for the purpose of giving origin to service lines for the purpose of general supply." Difficulties may arise in interpreting this, as, for instance, in cases where the same conductor is at one part a feeder and at another a distributing main; but it is one of those things which must be left to custom and precedent.

The other definitions need not detain us now, except that two important ones have been added in the new forms—"The expression 'consumer' shall mean any body or person supplied or entitled to be supplied with energy by the undertakers." "The expression 'consumer's terminals' shall mean the ends of the electric lines situate upon any consumer's premises and belonging to him, at which the supply of energy is delivered from the service lines." The consumer's terminals are the point of demarcation between the possessions of the undertakers and their customers; they need not be binding posts.

In the clauses headed "Area of Supply," an important novelty was introduced last year, and has been retained in the new model for companies, expressly prohibiting the undertakers from supplying outside the area granted to them without further statutory powers. This is a sacrifice of their common law rights which they are required to make in consideration of the special privileges they acquire. This provision is being carried out by mutual agreements between the London companies. The old Orders, and the Liverpool and Swansea Orders of last year, provided for the division of the whole area into two districts, scheduled A and B respectively; the A district alone being the area for which powers are immediately granted, and in which supply is compulsory; while the B district was intended to be added piece by piece, practically at the option of the undertakers. The general effect of this was to induce undertakers to apply for very large districts, the greater part of which were in the B schedules, over which they thereby acquired a sort of prior right of occupation without incurring any liability. This was altered last year and a single district substituted, to the whole of which the "Compulsory Works'" clauses apply.

(To be continued.)



A SWISS CONDENSED MILK FACTORY.

We give herewith an illustration of the interior of one of the largest condensed milk factories at Vevey, in Switzerland, for a description of which we are indebted to our French contemporary *La Nature*. The manufacture of condensed milk has been considerably developed in Switzerland during the last few years, and two large factories belonging to the Anglo-Swiss Milk Company have been erected at Cham and Guin, while the Nestlé Milk Company have worked at Vevey, Bercher, and Payerne. The export in 1887 reached the large total of 494,720 cases, containing four dozen tins each, and in 1888 of 520,000 cases, while last year the total was greatly in excess of this latter number. Some 15,000 cows belonging to the peasants of 250 villages contribute the milk to the several centres, where the fresh milk is cooled in large refrigerators and bought by the manufacturers. It is then removed to the factory, where it it is first heated over a large water bath, and subsequently in large copper vessels, to a temperature not exceeding 80° C. These copper vessels are arranged in series, as shown in our illustration, and are connected with pipes leading to a vacuum exhausting apparatus similar to those used for the evaporation of beetroot juices in the manufacture of sugar. The milk is sweetened by the addition of 13 per cent. of refined sugar, which is aspirated into the copper vessels through a siphon at the beginning of the operation. The condensed milk, as soon as it reaches the requisite degree of concentration, is removed from the copper vessels, cooled, and placed in large receivers surrounded by running water, and thence transferred to the small tins, which are at once soldered hermetically.

THE SMOKELESS GUNPOWDERS.

The secrecy of manufacture of smokeless powders by the different European Government officials has given an unusual interest to the various patents relating to this subject, and it will be in the recollection of our readers that Sir Frederick Abel, in his recent lecture on "Smokeless Explosives" at the Royal Institution, pointed out that the question of the ultimate adoption of smokeless powders for military and naval purposes was only a matter of time. The so-called "amide powder," formed from a mixture of potassium and ammonium nitrates, was at one time the most important of these new explosives. Unfortunately, it was found to deteriorate when stored in a confined space, and hence a new material was desired. The French produced a powder for their Lebel rifle which contained picric acid, and last year it was believed that the manufacture of this explosive in France would confer a considerable benefit on the manufacturers

A SWISS CONDENSED MILK FACTORY.

of picric acid, as this material had hitherto few commercial applications. At present the smokeless powders which give the best results are those obtained from different nitro-celluloses or modifications of gun-cotton. Nobel obtained from gun-cotton by dissolving it in nitro-glycerine, a powder which was both smokeless and unaffected by water, but as this explosive gives no solid products when detonated, there seems to be a difficulty in using it for the purpose for which it was devised, since no lubricant is produced in the bore of the gun to reduce the friction of the metal on metal. The composition of this Nobel powder is as follows:—

Nitro-glycerine	100
Nitro-cellulose	50–200
Camphor	10–25

The camphor is first dissolved in the nitro-glycerine, and then, after the addition of 200–400 parts of benzene or amyl acetate, the nitro-cellusose is stirred into the solution. On evaporating the benzene at a temperature of 50°-60° C., the explosive is left in a gelatinous sheet, which can subsequently be cut into small cubes. As camphor is a very volatile body, the explosive made in this way is not of uniform composition; and more recently M. Nobel has proposed a mixture of 50 parts nitro-glycerine with 50 parts of dinitro-cellulose, the latter being made to dissolve in the former by means of benzene. He claims for this modification of his original powder that it is of uniform composition and permanent in moist air. The Nobel powder is of a brown colour, and is one of the smokeless explosives which has recently been experimented upon by the German Government.

The French smokeless powder already alluded to is known under the name of "poudre vieille," and has been in use in the French army since 1887, but the secret of its composition has been so well guarded that no other Government has been able to produce a similar powder. It possesses many good qualities, and has been kept for a considerable length of time without undergoing any deterioration.

In Belgium the powder manufactory of Wetteren have produced a smokeless powder by dissolving nitro-cellulose and barium nitrate in amyl acetate. It is known as "No. 32," and is sent into the market in thin sheets resembling brown paper. The Austrian firm of Wolf & Co. have also introduced one of these new explosives. Their compound consists of gun-cotton which has been partially dissolved in acetic ether or nitro-benzene, and subsequently dried by driving off the solvent at a low temperature. In this way each particle of gun-cotton is coated with a glazed surface, which retards its decomposition and renders it available for use in firearms.

Maxim has also patented a modification of gun-cotton, which is obtained by first saturating the cotton with acetic ether vapour, when it can be compressed into any desired shape, and subsequently obtained in granules or powder by gently evaporating off the solvent.

The well-known Hengst powder is obtained by nitrating straw, and then digesting the nitro-cellulose so formed in a hot bath of the following composition:—

Water	1,000
Saltpetre	12·5
Potassium chlorate	3·125
Zinc sulphate	12·5
Potassium permanganate	12·5

After this treatment for some hours the material apparently absorbs some of the salts present in the water, and when dried by pressure can be obtained in the form of a fine powder. In an amended patent of last December the patentee has made some slight alterations in the method of manufacture. In America, gellite, or emmensite, so called from Dr. Emmens, of New York, is now being experimented with. It is a nitro-cellulose saturated with ammonium picrate, and was first introduced to the American market in 1888. The nitro-cellulose used in its manufacture is prepared from paper, care being taken that the nitro-product does not contain any trace of free nitric acid. It is then warmed with picric acid, and a current of ammonia gas passed through the liquid to convert the acid into the ammonium salt. Other powders of lesser importance containing nitro-cellulose have been patented by Turpin in 1888 and Gaens in 1889. The Gaens powder is being manufactured at Hamburg; it has the fellowing composition:—

Nitro-cellulose	25
Potassium nitrate	60
Ammonium ulmate	15

This mixture is dissolved in acetic ether, and the mass compressed and granulated; it is then carefully dried. The ammonium ulmate, which is the novel ingredient in this formula, is obtained by digesting peat or turf with ammonia; the ulmic acid present in the vegetable mould is thus dissolved, and from the solution so obtained the ammonium ulmate is prepared. It is difficult to see what especial virtue this material has over other organic acids of more definite constitution.

In this country, although apparently the official experiments have not been sufficiently decisive to warrant a new departure of any magnitude, considerable progress has been made. Among the earlier patents we find that Sir Frederick Abel, in 1886, laid claim to a smokeless explosive consisting of nitro-cellulose powdered and dried, and mixed with one-tenth to one-half its weight of dried ammonium nitrate. The mixture is then moistened with petroleum ether and moulded into small cubes, which are finally dried by gentle heating. The powder is then treated with a solvent which attacks the surface of the nitro-cellulose. On again drying, each granule is found to be coated with a superficial layer of varnish, which protects the ammonium nitrate from absorbing moisture from the air. Sir Frederick Abel has also produced an explosive named "cordite," which is similar to that patented by M. Nobel, but is obtained in filaments of a light brown colour.

Johnston and Borland have also patented an explosive which is obtained by dissolving nitro-cellulose in a solution containing camphor. After gentle heating the solvent is driven off, and an intimate mixture of the nitro-cellulose with the camphor is obtained. On heating this mixture in a closed vessel, the camphor being

Digitized by Google

volatile produces a sort of glazed film on the surface, which renders the mass hard and suitable for use.

More recently, Colonel Noble has succeeded in producing at the gunpowder factory at Waltham Abbey a new smokeless powder, termed "Walthamite," which has already given satisfactory results when fired in the new magazine rifle at the Government ranges at Enfield Lock. Its composition is at present not made known, but it is understood that peat is used in its manufacture, and that therefore it may contain as one of its ingredients ammonium ulmate similar to the Gaens powder, to which we have have already alluded.

THE SOCIETY OF CHEMICAL INDUSTRY.

LONDON SECTION.

At the meeting on Monday, the 2nd inst., Messrs. Cross and Bevan read a paper, entitled "Some Considerations on the Chemistry of Hypochlorite Bleaching," in which they advanced evidence in support of the following points:—

(*a*) Bleaching by means of the hypochlorites is attended with chlorination of the fibre.

(*b*) That there is less chlorination of the fibre when magnesium hypochlorite and electrolysed magnesium chloride are employed instead of bleaching powder.

(*c*) That chlorination of the fibre takes place is proved by the presence of organic chlorides in the washed pulp, and in the amount of soluble chloride and free base being less than should be the case if no such change takes place.

It consequently follows that bleaching by bleaching powder is a different chemical action from that in which permanganates and hydrogen peroxide are employed.

The authors show that bleaching by means of hypochlorites includes the three chemical changes of hydrolysis, oxidation, and chlorination, and point out that these changes are influenced by the temperature at which the bleaching is performed, by the quantity of base present, and by the strength of bleaching solution employed.

Bleaching by means of sodium hypochlorite is very similar to that effected by bleaching powder, the amount of base retained by the fibre and extent of chlorination being nearly the same. The chlorination appears to be due to the presence of organic substances of the nature of ketones in the fibre, and the organic chloride produced in this way has no doubt feeble acid characteristics which bring about the retention of the basic constituents of the bleaching liquid by the bleached fibre.

Notes.

THE BRITISH ASSOCIATION.

The sixtieth annual meeting of this Association will commence on Wednesday, the 3rd of September, at Leeds, under the presidency of Sir Frederick Augustus Abel. The following are the presidents of the various sections:—Mathematical and Physical Science, Mr. J. W. L. Glaisher; Chemical Science, Professor T. E. Thorpe; Geology, Professor A. H. Green; Biology, Professor Milnes Marshall; Geography, Colonel Sir Lambert Playfair; Economic Science and Statistics, Professor Alfred Marshall; Mechanical Science, Captain A. Noble; Anthropology, Dr. John Evans. The local secretaries are Messrs. J. Rawlinson Ford and Sydney Lupton and Professors Miall and Smithells.

THE INDUSTRIES OF BAVARIA.

Upper Bavaria has a population of 1,006,761, who are chiefly engaged in the cattle-rearing industry. At Munich there are the famous breweries, whose products are exported to all parts of the world under the name of Munich beer. There still exist artificial flower, colour, mathematical and optical instrument factories, tanneries, and paper mills. Clock wares are highly wrought, and at Munich also railway locomotives and waggons are made. Lithography there is of high repute, and painting, sculpture, and ornamenting give employment to numerous artists. Lower Bavaria has a population of 660,802, engaged especially in agriculture and in trading in products of the soil. There are, however, several factories of ceramic and glass articles, and peltries. The snuff consumed in the kingdom is chiefly prepared in Lower Bavaria. The Palatinate contains 696,375 inhabitants. The products of the soil are wheat, tobacco, wine, beets, and various fruits; cotton yarn, cotton velvet, cloths, plushes, glassware, nails, iron stoves, and chemical products are also manufactured. The Upper Palatinate has 537,990 inhabitants, devoted principally to agriculture; however, it also produces cloths, paper, porcelain, glassware, and alcohols. Upper Franconia has 576,703 inhabitants, almost exclusively agricultural, and occupied particularly with market gardening and the culture of table fruits. There are also cotton mills and weaving sheds. Musical instruments and the famous Venetian pearls are also made there. Central Franconia is peopled by 671,966 inhabitants. The products of its soil are principally tobacco, hops, and wheat. Lower Franconia, with 619,436 inhabitants, produces celebrated wheat and wines. Swabia, with 650,166 inhabitants, exports large quantities of cheese, and supplies cotton and woollen yarns, sewing threads, typographic machines, paper ware, brass, watch springs, saw blades, and matches.

MANUFACTURE OF PAPER IN THE UNITED STATES.

Americans are beginning to compete with this country in the paper trade. The English Consul at Boston, in reporting on the commerce of his district during the past year, states that the manufacture of paper, though not very profitable, owing to the competition of the increasing number of factories, has been brought to such a high state of development, and reduced so much in cost of production by improved machinery and the successful use of wood pulp under a special process, that it has become possible to establish a large export trade, not only in rivalry with, but directly to, the United Kingdom. A market has also been found in Australia and elsewhere.

PROFIT SHARING.

The policy of a firm or company sharing profits with the men employed seems on the face of it to be an equitable and just arrangement, and calculated to have good effects. A great deal of noise is being just now made in the American papers over a scheme put forward by the Illinois Steel Company, to pay to their workmen who have been with them a year 1 per cent. on their wages, 1¼ per cent. after eighteen months' service, and ¼ per cent. additional for every six months up to five years, when no further advance will be made. Any cessation from work during the period will disqualify for the benefits. This our American friends term "profit sharing," but this is a perversion of the English language. The basis of reward is the wages paid, and not the profits made by the company. Under such an interpretation, everyone who has wages paid him is a profit sharer, which is manifestly absurd. The system is merely one of giving a premium for continuous service and good behaviour.

THE McKINLEY TARIFF BILL.

In referring to this Bill, which passed through the House of Representatives on the 21st ult., our American contemporary, *The Iron Age*—in the issue just to hand—says: "So far as the iron and metal trades are concerned the Bill presents only a few modifications which will be of widespread influence. This, of course, is particularly true of the tinplate duty, which will create a great industry and will largely increase the consumption of raw material. It is probable that a sharp contest between the American and Welsh makers will soon follow, so that an interesting and momentous period lies before that particular trade. It is not improbable that the greater part of the stock abroad will be rushed over to this country as soon as it becomes certain that the Bill will become a law. In the metal trades the reduction in the duty on copper is of very little consequence, the only really important feature of the measure being the duty on foreign lead ores, which will keep Mexican free lead out of our markets. Even now the price of the metal has risen materially. Whether the frontier smelters will find it possible to handle any quantity of Mexican ore under the drawback system remains to be seen. The contest in the Senate, and the compromises in subsequent conferences of both Houses, are likely to deal with other parts of the Bill than the metal schedule, so that, with the exception of minor modifications, the McKinley rates are likely to prevail."

ODORISING WATER GAS.

Dr. Lewkowitsch, in a recent note in the *Chemical News*, suggests the use of thio-acetone for odorising water gas. This compound can be readily prepared, and has a characteristic penetrating odour, which would render it possible to detect the escape of very small quantities of water gas odorised with it. Like mercaptan and several other compounds which have been suggested for this purpose, this body contains sulphur, and may therefore not be so suitable as acrolein, which the author also suggests for the same purpose. The removal of the poisonous carbon-monoxide itself, and the substitution of an equal volume of hydrogen gas, has been patented by Professors Crookes and Ricarde-Seaver, but we have not been able to ascertain whether the process has been tried on a sufficiently large scale to demonstrate its advantages. They pass the water gas over red-hot soda-lime, and the action of the soda-lime on the gas may be thus expressed—

$$2NaOH + CO = Na_2CO_3 + 2H.$$

Carbonate of soda, it will be noticed, is reproduced in the process, and only requires recausticising with fresh lime for a subsequent operation. The cost of lime has, therefore, to be added to the cost of manufacture of the gas, but, on the other hand, the calorific value of hydrogen is much greater than that of the carbon-monoxide it replaces. The low density of hydrogen makes it more liable to diffuse than even carbon-monoxide through leaky fittings, so that it would apparently be still of advantage to odorise the hydrogen.

THE TRADE OF DAMASCUS.

It is really a comfort to find a British consul who says that our merchants do well, many seeming to consider it necessary to grumble at them each time that they write to the Foreign Office. Consul Dickson of Damascus gives a gratifying account of our trade there, for out of imports of the total value of £670,760 our share last year was £354,027, an increase of £119,356 compared with the previous year. "The activity of British firms, in making themselves known by advertisements, circulars, and correspondence with local merchants, has helped somewhat to promote business relations with England and to increase the demand for articles of British manufacture." The import of cotton goods has greatly increased; so has yarn. Iron has also improved, but hardware and glass have fallen off to a slight extent.

POLISH TRADE.

Improvements in Custom House arrangements will facilitate trade between Dantzig and Warsaw, and consequently have a beneficial effect on British trade with the latter district, which is mainly carried on through Dantzig. Last year's foreign trade showed a considerable improvement on the whole. The import into Warsaw of woollen textiles advanced to a marked extent, and raw wool also advanced. Steel and iron goods also increased. The cause of this improvement was largely a more favourable rate of exchange. The industries of Poland have made substantial progress, wool weaving and spinning mills, cotton mills, and other manufacturing establishments increasing in number. The industrial centre in which the advance is most prominent is the town of Lodz and its neighbourhood, in the Government of Pietrokow.

IMPORTS AT BARCELONA.

The total quantity of raw materials imported last year at Barcelona are reported by the British Consul there to have been 593,645 tons, an increase of 34,155 tons over the previous year. Of this 395,495 tons came from Great Britain and our Colonies. Textile materials from England and India showed little change compared with the previous year. The falling off in the quantity of pig iron, steel, and smelting iron amounts to 5,897 tons; the total amount is not given. The cause is that native iron from Gijon and other parts of the North of Spain is taking the place of English and Scotch iron. The total weight of manufactured goods imported in 1889 was 52,742 tons, against 51,862 tons in 1888. There was an increase in the importation of the following articles—viz., worked marble, colouring extracts, chemical and pharmaceutical products, soap, candles, cotton and linen threads, linen and wool textures, silk threads, paper, leather goods, engines, machinery, toys, and indiarubber goods. There was a slight decrease in the following articles of import—viz., porcelain, hardware, copper, brass and zinc articles, palm oil, starch and corn flour, and paste-board and card-board. About 17,790 tons, or one-third of total amount, came from Great Britain, and consisted of glass, bricks, hardware, drugs, chemicals, cotton and wool textiles, textures, machinery, and paper. It is reported that there is no increase in the imports of spun yarn from the United Kingdom. The trade in wet spun yarns has been lost, owing to Belgium, Germany, and Austria being able to supply them at lower rates.

7751. Frater, T. ..... Washing machines.
7752. Muschamp, P. ..... Ball-bearing pedestal.
7753. Horne, W. ..... Utilising tides for motive power.
7758. Evans, T. ..... Tubular boilers.
7759. Macnaughton, J. ..... Breechloading firearms.
7761. Sloan & Barnes ..... Manufacture of wood wool.
7762. Barber, T. W. ..... Self-centering chucks.
7763. Wood & Whitaker ..... Boiler furnaces.
7772-3. Martin, E. ..... Filtering machinery.
7782. Boultbee, F. R. ..... Feed and guide for saw benches.
7791. Brining & Lister ..... Nail-driving machines.
7793. Smith, W. ..... Machinery for grinding plate glass.
7797. Hood, W. ..... Pile-driving machines.
7798. Simpson, G. ..... Locomotive engines.
7802. Hayes, G. ..... Metallic lathing.

20th May, 1890.

7807. Davis, G. D. ..... Rotary engines.
7813. Goude, Goude, & Goude Baling press.
7817. Orton, W. ..... Paring machines.
7820. Bates, F. G. ..... Cementation process.
7823. Sagar & Sagar ..... Carving machinery.
7826. Locher, E. ..... Transporting passengers and goods by air pressure.
7829. Hemingway, W. ..... Carding engines.
7833. Hochedez, A. J. ..... Safety bolt.
7843. Weaver, I. D. ..... Switch points.
7846. Byers, W. L. ..... Anchors.
7848. Palmer & Ware ..... Candle-moulding apparatus.
7849. Jobling, J. A. ..... Pots for melting glass.
7852. Boult, A. J. ..... Computing machines (*Sharpe*).
7856. Cherry, H. J. ..... Heeling machinery.
7857. Jennings & Byrne ..... Washing machines.
7861. Monro, C. E. ..... Typewriting machines.
7863. Bartlett & Keuffel ... Crank connections.
7864. Stuart, S. ..... Channel iron.
7865. Kadzidtoroski, A. R. ... Detachable link toothed chains.
7866. Williams, W. P. ..... Street indicators for tramway cars.
7869. Smith, C. R. ..... Seamless gold-plated wire.
7870. Hale, G. C. ..... Portable water towers.
7872. Marzin, L. ..... Steering apparatus.
7873. Perry, F. J. ..... Embroidery machines.
7879. Lycoudio, P. S. ..... Ordnance.
7881. Szeniowski & Piatkowski ..... Centrifugal machines.
7885. Bilgram, H. ..... Machines for manufacturing cigarettes.

22nd May, 1890.

7886. Norman & Simpson ..... Furnaces.
7888. Shipman, J. T. ..... Tubular boilers.
7892. Atterton, J. ..... Machines for washing roots.
7898. Jones, J. ..... Hangers for belt guide pulleys.
7899. Collis, A. B. ..... Engine governor.
7904. Hall, O. S. ..... Looms.
7906. Wootton, J. ..... Circular saws.
7909. Smith, M. ..... Printing machines, &c.
7911. Moore, E. ..... Ironing machine.
7912. Cordes, H. ..... Shot-making apparatus.
7915. Anderson, R. ..... Steam engines.
7919. Douglas, G. ..... Machinery for pressing and finishing textile fabrics.
7920. Bennett & Hides ..... Gas engines.
7929. Galloway & Beckwith Water tube boilers.
7933. Bellach, H. ..... Stamping sheet metal.
7957. Clayton, Shuttleworth, Shuttleworth, Clark, & Gamble ..... Thrashing machines.
7942. Edwards, E. H ..... Cement kilns.
7950. Robinson, G. W. ..... Cork-cutting machines.
7952. Lever, Holland, & Todd Steam boilers.
7953. Lever, Holland, & Todd Boiler furnaces.
7955. Williams, J. ..... Hydraulic engines.
7957. Montbith, J. ..... Rotary engines.
7959. Smith & Smith ..... Locks and bolts.
7964. Baker, W. ..... Breechloading small arms.
7966. Jones, J. ..... Rotary bookcase-making machine.
7967. Weir & Weir ..... Steam-heated evaporators
7969. Agnel, A. ..... Hammerless gun.
7973. Haddan, H. J. ..... Grinding discs (*Snissaert*).
7974. Fowler, A. B. ..... Boot treeing machines.
7980. Meunier, Père, & Meunier, Fils ..... Spinning machines.
7985. Barclay & Duncan ..... Lock nuts.
7995. Thompson, W. P. ..... Steam engines (*Schaefer*).
8003. Cole, W. ..... Centrifugal machinery.
8005. Lake, H. H. ..... Ingots for plated wire (*Smith*).
8006. Westbrook & Burns ... Dies and stocks for cutting threads.
8010. Broadbent, E. W. ..... Sewing machines.
8011. Gastrell, J. P. H. ..... Levers and linkages.
8012. Gastrell, J. P. H. ..... Linkages for transmitting motion.
8017. Wolseley, F. Y. ..... Universal joint for shafts.
8021. Hale, J. M. ..... Ships' boats, &c.
8022. Marr, J. N. ..... Clearing tramway lines.
8024. Chadwell, C. ..... Tramway points.

23rd May, 1890.

8038. Kelly, R. ..... Bending pipes, &c.
8039. Glinsmann, H. C. ..... Washing machines.
8041. McGregor, A. ..... Reaping and mowing machines.
8045. Bayly, J. P. ..... Nut lock (*Thompson*).
8050. Torkington, J. ..... Smoke-consuming apparatus.
8053. Booth, W. A. ..... Sectional warping machines.
8060. Stott, J. ..... Printing machines.
8061. Cooper, E. W. ..... Looms.
8063. Boardman, J. W. ..... Standards for wire fencing.
8065. Eastman, M. ..... Permanent way.
8067. Foxwell, J. B. ..... Hollow fire-bars.
8069. Douglas, S. ..... Apparatus for propelling vessels, raising water and other liquids, and compressing gases.
8071. Seddon, F. ..... Valves.
8074. Woods & Woods ..... Crushing mill.
8078. Martin, A. ..... Apparatus for clipping animals.
8079. Hartmann, E. ..... Railway brakes.
8080. Lederer & Plouhy ..... Carding machines.
8092. Williams, J. N. S. ..... Sugar cane slicing machines.
8093. Odell, J. B. ..... Type distributing apparatus.

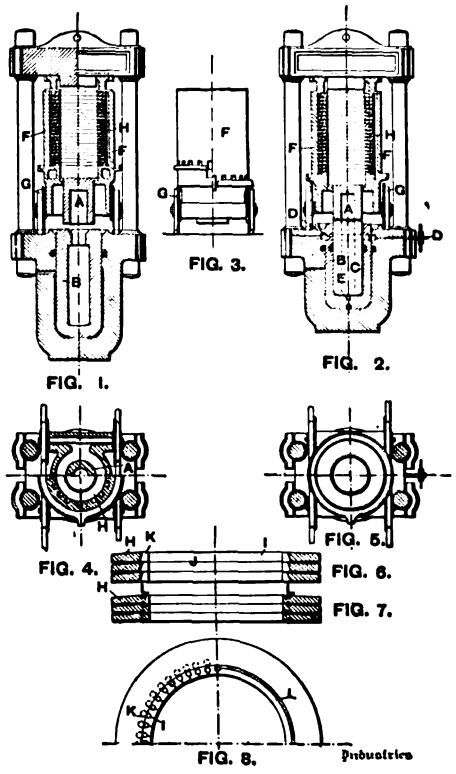
ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

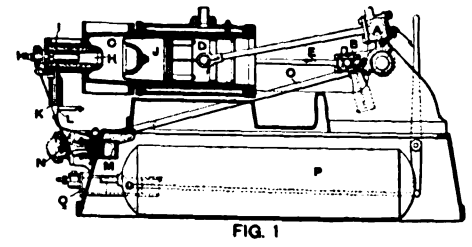


ENGINEERING.

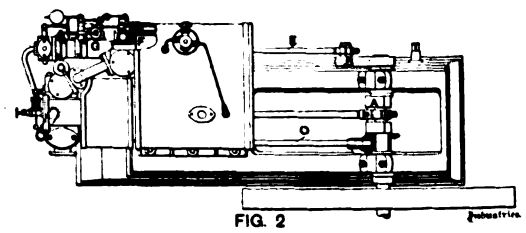
Rotary Engines.—*G. J. Clarkson, Stockton-on-Tees.* (*R. C. Fisher, Ontario, Canada.*) The illustration shows a sectional elevation of this improved rotary engine. Upon the driving shaft is secured the three cylinders B, C, and D. These cylinders are fitted with pistons which are pressed against the partially open ends of the cylinders by coiled springs. The cylinders B, C, and D are enclosed in a chamber E, which has a steam inlet F and exhaust G. The steam inlet is fitted with a slide valve H worked by a bowl travelling in the groove I; the inlet is also fitted with a sliding piece J. The action is as follows: The shaft is first revolved by hand; this causes the rod K to draw the valve down and admit steam into the space L. The

block J is thus forced downwards, and its rounded edge pressing against the framing of the cylinders causes them and the shaft to revolve. When the block J has descended sufficiently to expose the passage L the steam enters the space between the case E and the piston of the cylinder B. The piston is then pressed into its cylinder against the resistance of the spring, and the cylinders are thus caused to rotate. Before the head of the cylinder reaches the port G and the steam is exhausted, the supply is cut off and the steam used expansively. The opening M is the outlet for condensed steam. Four claims are made.—No. 19110. November 28th, 1889. 8*d.*

Presses for Extracting Oil.—*W. P. Thompson, Liverpool,* (*A. Schumacher & C. Tschiffeli, Marseilles.*)—To secure a large return from oil mills it is proposed to treat the articles to be pressed in metal cages, and under a much greater pressure than formerly. The increase of pressure in this system is attained by diminishing the area of the cages in proportion to that of the pistons of the presses; the greater difference of area the greater will be the pressure. Fig. 1 is a vertical section of one form of press constructed according to this invention; Fig. 2 is a similar view of a modification; Fig. 3 is an elevation of the cage of the improved press; Fig. 4 is a section; Fig. 5 is a sectional plan of Fig. 2; Figs. 6, 7, and 8 are details. The piston of the press being of too great a diameter to penetrate into that part of the cage where the materials to be pressed are placed, recourse is had to one or the other arrangement of pistons here mentioned, namely:—First, to terminate the bottom of the cover of the cage by a pressure cylinder A of a certain height having a vacant

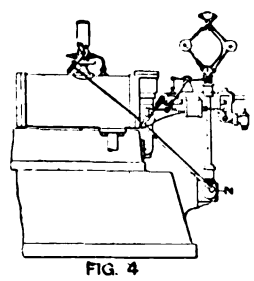


space around its lower end in which the piston B can lodge when raised (see Fig. 1). Second, to employ a second piston C resting inside the first B (see Fig. 2). The inner piston C rises first, the outer one B being held stationary by a brake D. A lifting valve E is provided. At the commencement of the pressure the brake D holds the large piston B immovable until the small piston has produced its effect. The brake is then released, and, the valve closing itself by its own weight, the two pistons rise together. The cage F is composed of a metal case mounted on rollers or wheels G. In the inner side of this cover or case is a number of vertical grooves destined to allow the expressed oil to escape. In the interior of the above-named cage is piled, one above the other, a number of horizontal rings H or rundles of circular or rectangular section, or of any other suitable shape. These rundles are placed one above the other, and, as shown, are connected by horizontal joints J, to which is given more or less play according to the nature of the grain to be treated. The rundles are pierced with a number of vertical holes K with vertical openings I, destined to provide, in addition to the filtering horizontal joints, as many vertical filtering joints as desired. These rings or rundles preferably taper slightly from top to bottom, in order to facilitate the discharge of the oil bags. For the treatment of certain grains and oleaginous fruits, between the parts of the rundles which are in contact semi-circular channels L are formed, and, in order to prevent the pulp under the action of the pressure coming out with the oil, the channels thus made are filled with a little packing of hair, aloes, or any other filtering material, or even with a metal circle covered with one of these filtering materials. Five claims are made for the method of adapting presses to work at higher pressure, and for the manner of constructing the cage.—No. 8740. May 27th, 1889. 8*d.*

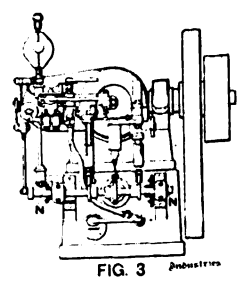


Compressing Plastic Substances.—*J. Price, London.*—In the moulds used in this class of machine difficulty has sometimes been experienced in removing the pressed material from the mould without effecting its shape, sharpness of outline, &c. In the manufacture of blocks and slabs of artificial stone this is an important feature. To prevent these defects the inventor constructs a mould as follows:—The head and bed plate of the press are fitted with loose plates to form the top and bottom of the mould, the plates having any pattern upon them required. The sides of the mould may be formed of one or several pieces. When the material has been compressed in this mould the plunger of the press is secured by means of any suitable mechanical device, and the sides of the mould are then slidden upwards or downwards, clear of the compressed material and the loose plates. The block of material, with the top and bottom plates adhering, is removed from the press and dried. When the block is sufficiently dry the plates are removed. Claims:—(1) In a hydraulic press, a mould of which the sides are capable of being moved independently of the top and bottom of the mould; (2) in a hydraulic press, a mould of which the sides are capable of being moved in combination with means for securing the plunger of the press during such movement; (3) a hydraulic press, in which after the material has been compressed the plunger is secured, the sides of the mould are moved away, the material is held between an upper and lower plate and then removed fixed between the said plates; (4) a hydraulic press constructed as and for the purposes described.—No. 6861. April 24th, 1889. 8*d.*

Ribbed Glass, &c.—*A. Drummond, Glasgow.*—Under the present system of manufacture, designs upon glass are produced by passing a roller, upon which the design is cut, over the glass when it is in a ductile state, or by pouring the glass upon the table in which the required design is cut. To facilitate the construction of the designs is the object of the present invention. The designs are cut or embossed in thin sheets of metal by presses, punches, and dies. This thin sheet, with the pattern so formed, is laid upon the table or bent round the roller. In the latter case the edges of the sheet are brazed together, and beween the pattern sheet and the roller is interposed a sheet of asbestos or other soft fire-resisting body. Claims: (1) In the manufacture of glass the application and use of sheets having designs or patterns impressed, stamped, cut, embossed, or perforated on them, said sheets being either made into cylinders and fitted on a smooth roller or core, or fitted on the surface of the glass casting table; (2) the combination with the roller or core of a casting table of a lining of asbestos or other heat-resisting material, interposed between the said roller and a cylinder, with the designs or patterns on it; (3) the combination with a glass casting table of a sheet, having designs or patterns on it, and secured to the table by means of rods or their equivalents.—No. 8760. May 27th, 1889. 8*d.*



Petroleum Motor Engines.—*O. Imray, London.* (*F. C. Glaser, Berlin*).—These improvements relate to the arrangements for effecting the supply of petroleum to the engine cylinder. The explosive mixture is produced and introduced into the cylinder of the engine by a jet of air which passes the orifice of the petroleum conduit and takes up a certain quantity of petroleum. The petroleum mixes with the jet of air in the form of a spray, and is thus delivered into the heated cylinder bottom. The cylinder is vertical, and has near its lower end a small chamber communicating by a valve directly to the cylinder. Pipes conducting the air current, petroleum, and extra air supply lead to this chamber, the air current pipe being at right angles to the axis of the cylinder, and the others parallel to it, and their openings just below that of the air current supply. When the valves are opened the current of air is forced directly into the cylinder and sucks in with it the petroleum and extra supply of air. Three claims are made.—No. 8778. May 27th, 1889. 8*d.*



Gas Engines.—*E. & H. Crowe, Middlesbrough.*—Improvements are made in the method of burning and mixing the gases, and in the construction of the valves, combustion chamber, and regenerator. Two pumps are worked by the engine, one compressing the combustible gas, and the other the air necessary for the combustion of the gas. The gases enter the combustion chamber and cylinder at the full pressure of the pumps, and are ignited by a flame produced by passing a small quantity of the explosive gas and air through a tube heated to redness. In the illustration of this invention Fig. 1 is a side elevation partly in section, Fig. 2 a plan, Fig. 3 an end elevation, and Fig. 4 another side elevation. There are two cranks, one, A, being the motor crank, and B the pump crank. The pumps F and G are in the same straight line, and have their pistons suitably coupled and driven by the connecting rod E. The motor cylinder C terminates in a combustion chamber H, which is surrounded by refractible material I, so that the heat developed by one charge may be utilised to heat the succeeding charge. D is the motor piston with a hollow chamber J. The ignition tube K is heated

by a burner L, and gas is passed through the tube by a small pump M driven by an eccentric upon the countershaft N. The shaft N is driven off the crank shaft by gear wheels and the shaft O. The action is as follows:—Assuming the pump pistons to be in and the motor piston receiving an outward impulse, then the pump piston will draw in through suitable valves a charge of air and gas. When both cylinders are full, the pistons return

and compress their charges, and towards the end of the stroke deliver them to the combustion chamber. Just before this, however, the pump M sends a quantity of inflammable mixture through the ignition pipe K. This flame meets the explosive charge as it is delivered by the pumps to the combustion chamber, and the charge is thereby burnt slowly, forming a gradual impulse. To start the engine the reservoir P is first charged with compressed air by a hand pump Q. This air is passed to the engine cylinder, and by its pressure gives to the engine sufficient motion to bring the other parts into work. Eight claims are made.—No. 7594. May 7th, 1889. 8*d.*

WIRE STRAIGHTENING AND CUTTING MACHINES.—*T. J. Crossley, Middleton Junction, Lancashire.*—Improvements are here made in these machines to permit thinner wires to be straightened and cut into equal lengths than is possible in the ordinary machines. The accompanying illustrations show a side elevation, plan, and end elevation of the improved machine. At the back of the headstock A, a pair of feed rollers I take in the wire W from a reel and push it through the spindle C, where, by passing through the eyelets of the bolts D, which are set out of centre, it is bent backwards and forwards and straightened in the usual way. The wire, on issuing from the spindle, passes between a pair of cutters mounted on a slide N. One of the

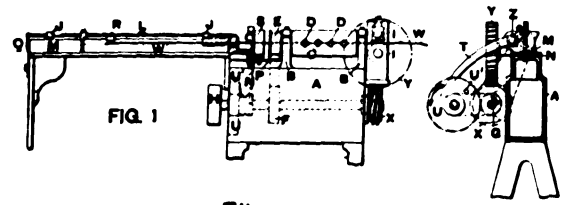

FIG. 1

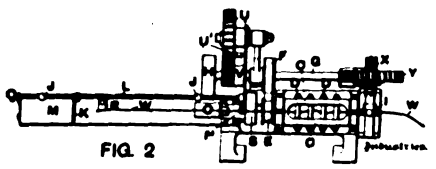
FIG. 3



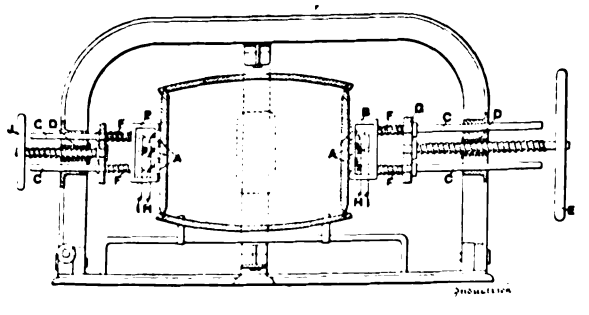


FIG. 2

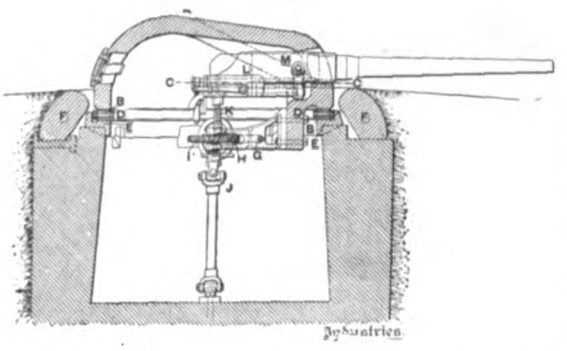
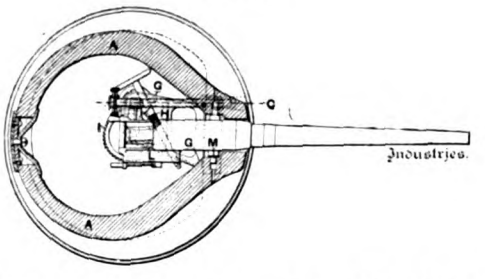
cutters is attached to a lever T, and it is operated by a pin U¹ lifting the end of the lever as the disc U is revolved. The disc U is driven off the main shaft by suitable connections. The wire, as it passes from the cutters, is conducted along the top of an inclined table M by a bracket O until it strikes against the stop K. The stop K is adjustably connected to a sliding rod L, which is attached to the slide N carrying the cutters. When the end of the wire, therefore, strikes the stop K, the cutters commence to move with the wire, so maintaining a constant distance between the cutters and the end of the wire, until the end of the lever T engages with the stud U¹, and the knives are operated. The wire is then discharged and rolls down the inclined table M to a receptacle, whilst the cutter slide, stop, &c., are returned to their normal positions by the spring P. If the wire is thin, it is supported, as it is pushed along the table, by a number of brackets similar to R. Claims: (1) In wire straightening and cutting machines the arrangement of an adjustable fence K, on a sliding rod L, connected to the cutter slide S, as described and illustrated; (2) in wire cutting and straightening machines placing the cutter slide N at such a distance from the striker wheel U that the cutter slide connected to a sliding rod carrying a stop fence cannot be drawn against said striker wheel by means of the wire pushing the stop fence before the striker has struck the cutter lever T and cut the wire, and employing a long stud U¹ as striker, as described and illustrated; (3) in wire straightening and cutting machine the arrangement of angle brackets R for curving and stiffening the wire substantially as hereinbefore described; (4) the general arrangement of wire cutting and straightening machine as described and illustrated.—No. 9037. May 31st, 1889. 8*d.*

BRANDING MACHINES.—*G. P. Nightingale, London.*—The machine is designed for branding casks, cases, crates, &c. The accompanying illustration shows a sectional elevation of the apparatus. The branding letters A are arranged in the face of a metal frame B. The frame B is supported upon rods C, which slide in the framing of the machine and are operated by a screw D and hand-wheel E. To make the connection flexible between the screw D and branding irons, the springs F are interposed between the cross-head G and frame B. The branding irons are heated by gas burners supplied with gas by pipes H and air by the pipes I. All that is necessary in branding a cask is to place it between the branding irons and screw up the hand-wheel E, the hand-wheel J being for adjustment. Claims: (1) A



machine for branding casks, cases, and the like, comprising one or more pairs of branding plates, one plate of each pair being capable of adjustment and the other movable for and during branding, with a rest or support for the cask, case, or the like, and spring cushions to the branding plates, substantially as and for the purpose set forth; (2) the machine having two hinged frames substantially as illustrated and described with pairs of branding plates and means for adjustment of one plate of each pair and for movement of the other plate during branding—No. 4019. March 14th, 1890. 6*d.*

BOILER FURNACES.—*H. J. Haddan, London.* (*F. F. Amoroso, Venice, Italy.*)—This invention refers to a method of burning liquid fuel in boiler furnaces. In the furnace is an open tray or tank of convenient shape and size to cover the area of the furnace, and of sufficient depth to hold a moderate quantity of the liquid fuel. Over this tray are journalled horizontally revolving perforated cylinders or rotary bodies provided with radiating wicks of asbestos. The wicks, as they revolve, dip to the required distance into the fuel, and so become saturated. As the wicks emerge from the fuel, the fuel upon them ignites from that burning upon the preceding wicks. The rotation of the wick holders may be done by the engine driven by the steam from the boiler, or by an independent engine or motor. While steam is being raised in the boiler heated by the improved furnace, the wick holders may be revolved by hand or by an independent engine. The wick tank is in connection with a fuel reservoir, the communication being controlled by a ball cock or float. Claim: The means for burning oil consisting of an open tank or tray for receiving said oil, and a system of rotary wick holders dipping into said tank or tray as and for the purpose described.—No. 10392. June 26th, 1889. 6*d.*



TURRET MOUNTING FOR GUNS.—*T. Nordenfelt, London.*—The turret is not intended to be lowered level to the ground in critical moments, but always maintained at the same height. The shape given to the turret and the mounting renders it safe against hits. A sectional elevation and plan of the turret is given in the accompanying illustrations. To keep the turret A as low as possible, the sights C are placed beneath the gun. The turret rests on a number of rollers B kept in position by rings D, and running upon the base ring E. A massive iron ring F protects the base of the turret. Beneath the gun is a bracket G carrying the turret gearing; the turret is rotated by a worm H and worm-wheel I. The bearings in which the worm is carried are on the bracket G, and they always retain the same position in relation to the turret, whose vertical axis coincides with that of the worm-wheel. The worm-wheel is mounted on the bracket G, so that it can yield to shocks resulting from rough treatment to which the turret may be exposed, and if the turret be slightly displaced it carries the worm-wheel and worm with it. The worm-wheel, however, is prevented from turning, its spindle being connected with the foundation of the turret by a double universal joint J. The bracket, however, is able to rotate around the wheel. The elevation and depression of the gun are effected by means of a common screw K, the top end of which is connected to the cradle L by a ball and socket, whilst its lower end runs through a nut

FIG. 1.

provided with trunnions, the bearings of which are placed in the above-mentioned bracket G. The cradle is carried by trunnions M, which project into the turret. Claims: (1) A fortification turret mounting of substantially the peculiar form described and supported upon rollers beneath its edge; (2) a fortification turret mounting supported upon rollers beneath its edge and turned by

FIG. 2.

gear flexibly connected to the foundation; (3) a fortification turret mounting supported upon rollers beneath its edge and carrying a worm and worm-wheel by which it can be turned, the worm-wheel being prevented from revolving by a flexible connection with the foundation; (4) a fortification turret mounting carrying the gun at the top of the turret, the embrasure being so formed and the gun being so fitted that the line of sight is beneath the gun; (5) fortification turret mountings substantially as described and shown.—No. 9498. June 7th, 1889. 8*d.*

WATER VELOCIPEDE.—*E. F. Bour, London.*—The framing of this apparatus is somewhat similar to that of an ordinary road tricycle, the wheels being here replaced by floats of a torpedo shape. To the rear end of the front float is mounted a small screw propeller; its shaft enters the float and is geared by mitre wheels to a vertical shaft passing out at the top of the float through a journal by which the float is secured to the frame. The vertical shaft is geared to a horizontal shaft in the framing, and is rotated by treadles of the usual volocipede construction, the treadles being geared to the horizontal shaft in a suitable manner. Seats and steering bars similar to those used upon velocipedes are provided for the navigators. The steering is performed by the rotating of the front propelling float about its vertical axis. Claims: (1) A water velocipede having three or more torpedo-shaped or equivalent floats arranged as described, with propeller and driving gear in one or more of the said floats; (2) a water velocipede having a pivoted leading float and two or more fixed trailing floats, shaped and connected by a backbone or framing as set forth, a screw propeller at the end of the leading float, and gear for operating said propeller and for steering the velocipede; (3) a water velocipede as described having pillars and attachments for slinging hammocks thereon; (4) a water velocipede having three torpedo-shaped floats arranged and connected as at the apices of a triangle, and a triangular netting, webbing, or grating slung or supported on a frame between the floats to serve as a flooring; (5) in a water velocipede, a leading float having a resilient fore part telescopically sliding therein and held projected by a spring to minimise the force of a collision.—No. 7256. May 1st, 1889. 8*d.*

LIQUID METERS.—*J. Lacoste, Paris.*—The meter is constructed with a single cylinder, the liquid being made to pass in alternately at opposite ends, and the flow being controlled by a combined arrangement of valves actuated by the piston at the end of each stroke. Referring to the illustrations, Fig. 1 is a longitudinal section, Fig. 2 a sectional plan on X X, Fig. 3 an end elevation, and Figs. 4, 5, and 6 details of the meter. The piston

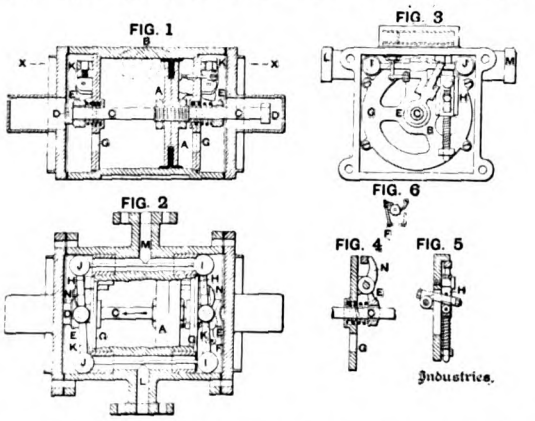


FIG. 1 FIG. 3 FIG. 2 FIG. 6 FIG. 4 FIG. 5

A has a double-ended rod C, upon whose ends are secured the collars D. The collars D at the end of each stroke press against levers E, which are held normally outwards by the springs F. On the levers E are projections N, which strike against the beams K as the levers E are depressed, and operate the valves I J carried by the beams K. The valves are spherical in shape, and control the inlet and outlet openings L M in such a manner that as the piston finishes its stroke to the right the outlet valve I is closed and the inlet valve opened, whilst the reversed effect is produced upon the other valves J. To hold the valves in the positions they are placed at the end of each stroke for the whole length of time of the succeeding stroke, use is made of the spring bolts H. Claims: (1) A liquid meter wherein a measuring cylinder containing a reciprocating piston has two longitudinal passages, the one serving for supply of the liquid, and the other for the discharge, which passages open into each end of the cylinder and are provided with four valves so connected together that at the end of each stroke of the piston the positions of all four valves are simultaneously reversed; (2) in a liquid meter such as is referred to in the preceding claim, mounting the supply and discharge valves at each end of the cylinder upon the opposite ends of a rocking beam, and connecting the two supply valves respectively together by a rod, whereby the simultaneous movement of all four valves is effected when one of the rocking beams is actuated by one of two spring levers, the other spring lever being depressed by a head on the piston rod at the end of a stroke, so as to relieve the other beam of its action; (3) in combination with the arrangement of valve gear referred to in the preceding claim, the use for locking the valves in position of two spring locking bolts, the end of one of which is made by its spring to project beneath the raised end of the one rocking beam so as to keep it in that position, the bolt being withdrawn by an arm acted upon by the piston at the end of its stroke, when it is required to reverse the position of the valves; (4) the construction of fluid meter combined and operating as herein described with reference to the illustrations.—No. 4393. March 20th, 1890. 8*d.*

ROTARY SHUTTLES FOR LOOMS.—*W. P. Thompson, Liverpool.* (*J. H. Mahr, Flensburg, Germany.*)—One or more of these shuttles are arranged in a loom for the purpose of conducting the woof or weft from one side only into the warp, whilst the ordinary shuttles, which have a reciprocating motion, are conducting the woof from both sides into the warp. Fig. 1 is an elevation of this apparatus, and Fig. 2 a section. The under part of the shuttles engage in guides A, which are of circular form, and resemble the letter I in cross section. On the guides are fixed toothed racks B, which engage in tooth-driving wheels C, and thus give the shuttles their motion. D is the groove in which the ordinary shuttle travels. The guide A and rack are formed with a recess E, which allows the shed to be formed. A hole F is formed in the supporting plate of the apparatus, through which

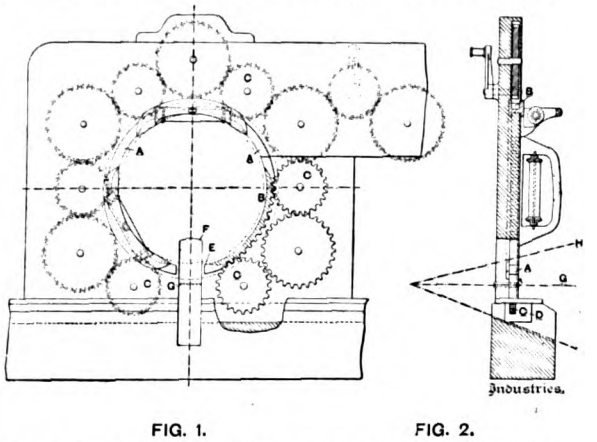

FIG. 1. FIG. 2.

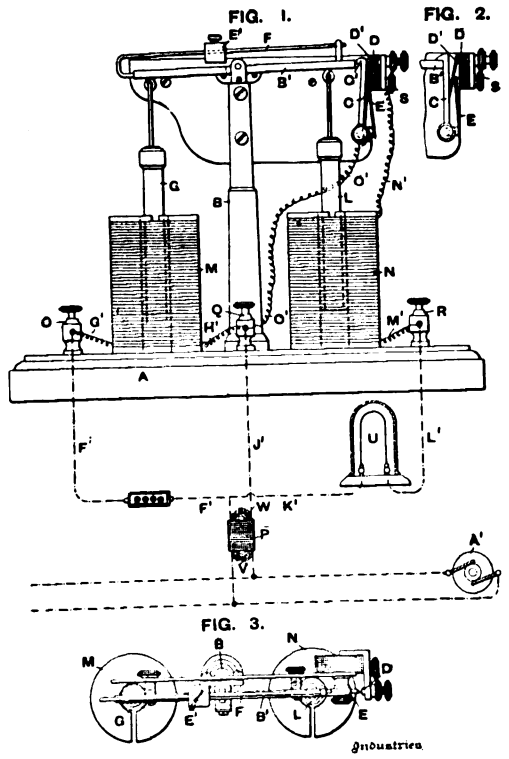
the warp threads are led. The warp beam is at one side of the plate, and the cloth beam at the other. The method of employment is as follows:—The warp threads G normally lie preferably rather below the periphery of the rack and guides A. When the apparatus is in the position shown in the illustrations the shed is formed by raising a certain number H of the warp threads and depressing the remainder I. The number and order of the threads raised will of course depend upon the pattern desired. The series of rotating shuttles is now passed through by means of the gear wheels actuating the rack, and the apparatus again assumes the position shown. The reciprocating shuttle or shuttles may also be passed if desired, or the shed may first be reformed and then the reciprocating shuttle passed. Claim: The

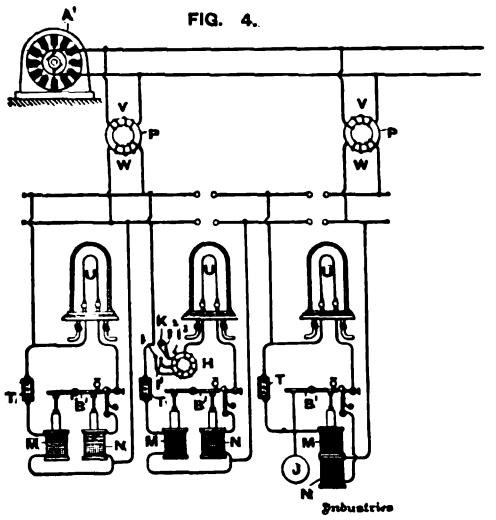
Digitized by Google



arrangement of one or more shuttles in a circular guide, which shuttles are adapted to be driven in one direction by wheels arranged either within or without the said guide, substantially as and for the purposes set forth.—No. 6519. April 16th, 1889. 6*d*.

PROPELLING CANAL BOATS.—*W. J. Griffiths, Greenwich.*—The boats are propelled by an endless chain mounted upon the boat and made to revolve with its lower half resting upon the bottom of the canal. The chain runs over a series of rollers arranged upon one side of the boat, and it is driven by a motor fixed in the bow of the boat and geared to one of the pulleys, over which the chain passes. As the chain is revolved its lower part has a tendency to be dragged along the bottom of the canal in a direction from the bow to the stern. The frictional resistance, however, between the chain and canal bottom prevents or partially prevents this action, and the boat is instead propelled forwards, the chain being lifted up at the stern and lowered again at the bow. If at any place the depth of water increases the chain will then assume a catenary curve at the bow and stern, and the length lying on the bottom of the canal will be shorter, but owing to the pulley at the bow being above the level of the top of the boat, and that at the stern level with the bottom, the difference in height ordinarily met with will not appreciably affect the resistance of the chain to moving on the bottom. Claim: The propulsion of canal boats by the frictional resistance on the bottom of the canal of an endless chain which is rendered capable of adjusting itself to moderate variations of depth of the canal by the pulleys on the boat being arranged as described.—No. 10260. June 24th, 1889. 8*d*.

STEAM VACUUM PUMPS.—*J. Brindley, Wolverhampton.*—This pump is of the type in which steam acts directly upon the surface of the water, the steam, after completing its work, forming a vacuum by condensation, so causing the pump to be recharged. The simplest form of this pump is constructed with a pear-shaped chamber of cast iron, terminating at its base with an enlarged portion to accommodate the suction and delivery valves. The steam-controlling valve is dispensed with, so that there are but two valves, one for the inlet and the other for the outlet. With a pump chamber constructed and fitted with valves as described, and with a continual flow of steam into it from the top, the water being pumped is driven out to the lowest level in the following manner. The steam acting upon the surface of the water forces it down and out at the discharge valve. As the surface of the water increases, due to the shape of the chamber, the steam rapidly expands and condenses in the lower part of the chamber. The water now rushes into the lower part of the chamber, and by its momentum refills the chamber, causing the action described to be repeated. When more economical working and a steady discharge are desired, a second chamber is used in conjunction with the first, and a valve controlling the admittance of steam to the chambers added. The valve is worked automatically so as to supply steam to one chamber as the other is refilling. Ten claims are made.—No. 10720. July 3rd, 1889. 8*d*.

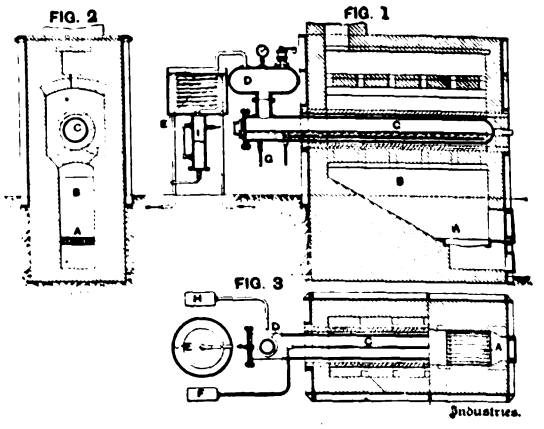


ELECTRICITY.

INTERRUPTING ELECTRIC CIRCUITS.—*W. P. Thompson, Liverpool. (The Westinghouse Electric Company, U.S.A.).*—It has been found that carbon filaments may be treated with advantage by alternating electric currents, and it is desirable that, after the treatment has proceeded to a certain point, the circuit should be automatically interrupted, so that all the filaments after treatment shall have the same resistance. This invention is designed o provide a circuit controlling device which shall insure that the circuit leading to the filaments shall be interrupted, and the

treatment terminated when the resistance of the filament has decreased to a certain predetermined point. The invention is illustrated by the accompanying figures. Fig. 1 is a front elevation, Fig. 2 a detail, Fig. 3 a plan, and Fig. 4 a number of these devices worked from one dynamo but arranged slightly different. Referring to the Figs. 1, 2, and 3, upon a balance lever B¹ are suspended the cores G L of two solenoids M N. The balance lever is retained in a horizontal position by a hook C. A¹ represents any suitable source of electric supply. In the circuit of the electric source is the primary coil of a converter P. The secondary coil of the converter has two circuits, one leading through an adjustable resistance to the post O, from O to the solenoid M, and then back to the coil through the post Q; the second circuit includes the filament U, the solenoid N, the contact device D D¹, and the post Q, which is in connection with the coil. When the filament is inserted and ready to be treated, the end of the lever B¹ carrying the core L is lifted, the arm C being pressed back against the spring E. The end of the catch or projection C¹ then rests against the smooth end of the lever B¹. This holds the spring D¹ against the point D, and completes the circuit, including the filament. Now, as the treatment proceeds, the resistance of the carbon becomes less by reason of the deposit from the surrounding atmosphere of hydrocarbon, and, therefore, more current passes through the solenoid N until the pull upon the core L exceeds that upon the core G sufficiently to draw the end of the lever B¹ downward across the point of the catch, thus allowing the arm C to be forced backward, separating the spring D¹ from the point D, and thus interrupting the circuit through the filament. As the current employed is an alternating current, no injury is done to the contact points by the interruption of the circuit, and, moreover, there still remains a closed secondary circuit through the coil M. It will be noticed, however, that the catch C¹ prevents the lever B¹ from immediately tilting in the opposite direction under the influence of the solenoid M acting upon the core G. Claims: (1) In an apparatus for treating filaments by means of the alternating current, the combination of two solenoids acting upon one or more cores in opposition to each other, a carbonised filament in circuit with one solenoid, and an automatic circuit interrupter in series

FIG. 4.



with only the last-named solenoid and the filament, the whole arranged in such manner that the circuit through the carbon filament shall be broken the moment it arrives at the predetermined resistance; (2) the process of treating filaments which consists in dividing an alternating current into two parts, each passing through a separate solenoid, one passing also through the filament to be treated, and a circuit interrupter and the two solenoids acting in opposition to each other on the same core, or on two cores mechanically united, and so arranged that when the two branches reach a certain ratio the one to the other, the circuit containing the filament shall be automatically interrupted; (3) the improved apparatus for treating filaments as described and illustrated.—No. 8815. May 28th, 1889. 8*d*.

ELECTRIC TRAMCARS.—*T. D. Hollick, London.*—The wheels of the tramcar are connected to the electromotor by the use of friction gearing. To prevent the loss of power caused by the necessity of obtaining sufficient pressure between the friction gearing to make them act, the inventor utilises for this purpose the weight of the body of the tramcar. The car is carried, with the intervention of suitable springs, upon the bearings in which the spindle of the electromotor revolves. This spindle is arranged transversely across the car directly above the wheels of the latter which are to be propelled, and upon the spindle are fixed two wheels or pinions of metal, indiarubber, or other material, which press upon the tires of the car wheels and set them in motion. The axles of the car wheels revolve in axle boxes of the usual kind, fitted to horn plates upon the framing which carries the electromotor. To permit of the adjustment of the pressure upon the friction gearing, the inventor arranges one or more cams, actuated by a screw under the control of an attendant, so that the horn plates, electromotor, and car can be raised or lowered to a small extent, and the pressure upon the gear so decreased or increased. Two claims are made.—No. 8468. May 21st, 1889. 8*d*.

CHEMISTRY.

DISTILLATION OF OILS.—*J. Dewar, Cambridge, & B. Redwood, Finchley.*—In distilling mineral oils, such as natural petroleum, or similar oil made from shale, coal, or other bituminous substances, in order to separate the lighter oils, suitable for lamps or other purposes, from the heavier oils, there is frequently a very large residue of heavy oil. The invention refers to an improved motion of obtaining lighter oils from such residue. The illustrations show one form of the apparatus for this purpose. Fig. 1 is a longitudinal, Fig. 2 a transverse, and Fig. 3 a horizontal section of the apparatus. A is the fireplace and B the combustion chamber of a furnace for heating the retort C. The front part of the retort communicates freely with a still head D which in turn communicates with a condensing coil E. A pump F forces the oil to be treated into the retort, and a pipe G provides the means of discharging the contents from the retort. The retort C being partly charged with oil, and the remaining space and the still head charged with air from the air pump H, the retort is heated and the oil vaporised under pressure. The oil vapour as it is developed passes to the condenser E and collects in the vessel I, from which it may be drawn off as desired. The less volatile vapours are condensed in the still head D and fall

back into the retort. Claims: (1) The herein-described method of distilling mineral oils and like products by vaporising them and condensing the vapour generated under a regulated pressure of air or gas; (2) for operating in the manner referred to the combination of a retort or boiler, a condenser, an oil pump, and an air or gas pump with their communicating pipes, as described. —No. 10,277. June 24th, 1889. 8*d*.

MISCELLANEOUS.

GLASS TANKS.—*J. Armstrong, London.*—The tanks are constructed for holding acids for the purpose of electric battery cells, &c., the object of the invention being to make them from rolled plate, or sheet glass. In a specially constructed kiln, heated by gas or fire, is placed a mould of the form of the tank to be constructed. Previously to placing the mould in the kiln, the glass sheet or sheets of the requisite size and shape to form the tank are placed upon the mould. The kiln is heated, and the flames made to play upon the glass, so softening it and causing the sides to bend over into and upon the mould. The flames are then directed upon the edges of the glass until they are heated to fusing point, when an apparatus is made to enter the mould and press the sheets into the shape of the mould. Another instrument is used to rub up and down the edges and weld them together. The mould is then reversed, and the tank removed into an annealing oven. The moulds and other parts of the apparatus are made hollow to admit cooling agents to keep them at the proper temperature. Wirework may be pressed into the glass at the time of pressing it into the shape of the mould. Claims: (1) Making boxes or tanks of glass from sheet or plate glass, by welding the corners or angles, with or without the wirework inserted; (2) in a furnace for making boxes of glass by process of welding the joints as described; (3) in a furnace for making boxes of glass by process of welding the joints, the use of a gas jet or hot flame to impinge upon the joint to be welded; (4) in the process of making boxes of glass, a tool used with pressure or an apparatus to unite the edges of the glass; (5) in a furnace for making boxes of glass, moulds made and constructed as described; (6) in a furnace for the purpose of making glass tanks the use of rails for sliding the moulds upon; (7) the general plan and arrangement of the furnace and apparatus for the purpose of forming glass tanks.—No. 7346. May 2nd, 1889. 6*d*.

APPARATUS FOR THE DIFFUSION OF DISINFECTING FLUIDS.—*A. R. Upward, London.*—The apparatus is adapted to be worked by the opening and closing of a door at the entrance to the room or closet in which the spray is to be diffused. The spray is caused by an air-forcing appliance either attached to the door or to the door frame, and operated by the opening and closing of the door. A tube of convenient length leads from the air-compressor to a spray nozzle of ordinary construction, and supplies the nozzle with the necessary blast of air. The feed pipe of the nozzle is immersed in a tank or vessel containing the disinfectant. To ensure the proper working of the air-compressor, it may be worked by a spring which is compressed by the opening or closing of the door, but released before the expiration of either movement, so that in its sudden recoil it forces the air to and through the spray nozzle. The force of the air supply is thus not dependent upon the rate at which the door is moved. Claims: (1) A spray-producing apparatus operated by the usual motion of the door; (2) a spray-producing apparatus, consisting of an air-compressing device, operated by spring pressure, the elastic extension or compression of the spring being set up and suddenly released by the motion of a door or other equivalent movement, the sudden exhaust of the air operating any form of blast spray nozzle for the dispersion of liquids; (3) in such a spray-producing apparatus a spring pressed air-producing device in combination with a rotating disc having projections which gradually reinforces and suddenly releases the spring of the air-compressing device; (4) in such a spray-producing apparatus an actuating disc and projections in combination with a pawl and driving ratchet wheel upon a drum, rotated by a line, cord, or band against the recoil, reaction of the internal spring by the motion of the door; (5) in such a spray-producing apparatus the combination with a spray nozzle feeding from a small reservoir containing the liquid to be dispersed of an auxiliary liquid supply cistern.—No. 7978. May 14th, 1889. 8*d*.

Copies of the British specifications may be obtained on application to H. READER LACK, Esq., ***Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every*** 10*d*. ***or fraction of*** 10*d*. ***Remittances exceeding one shilling must be made by Post Office Order.***

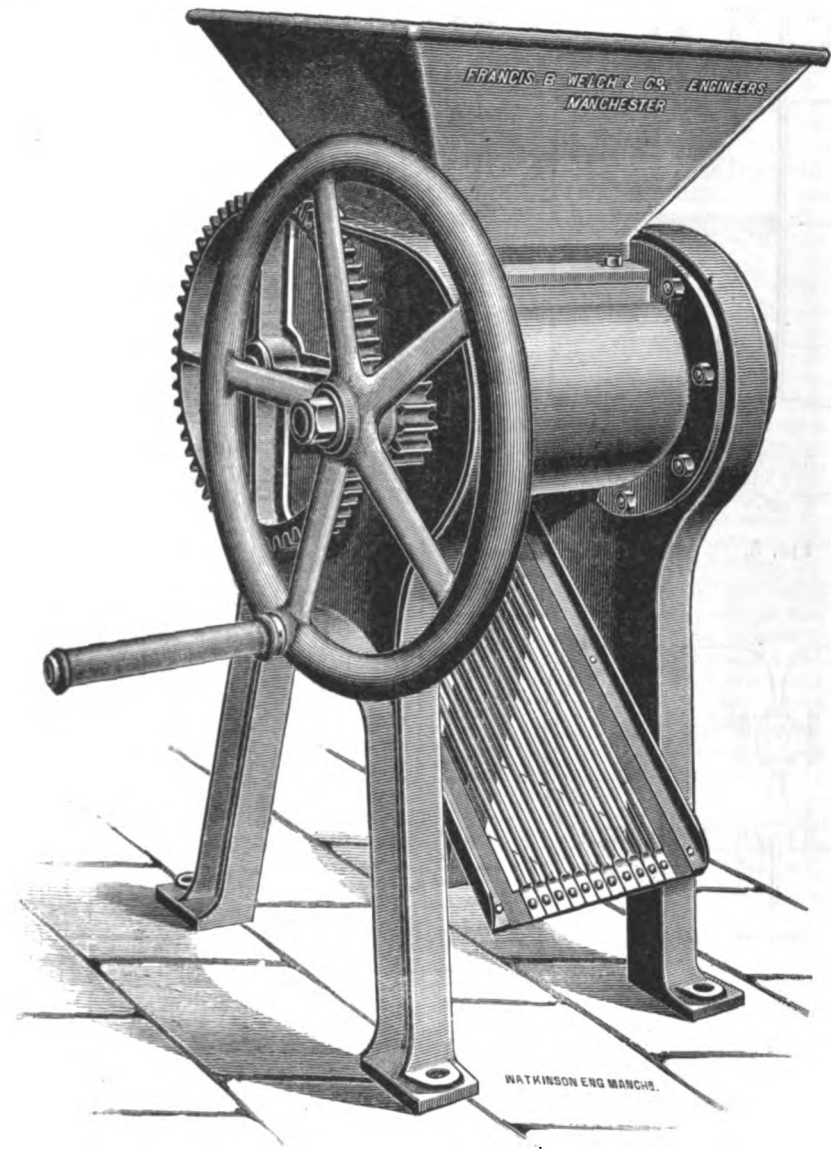
COKE CRUSHING MACHINE.

We illustrate herewith a machine for crushing coke, which is being made by Messrs. Francis B. Welch & Co., Atlantic Works, City Road, Manchester. It is specially adapted for use in connection with smiths' fires, and it can be worked either by hand or by steam power. The crushed coke falls upon an inclined screen placed under the machine for the purpose of removing the dust and finer particles.

THE DAIMLER PETROLEUM MOTOR.



It is claimed that the motor we illustrate below is distinguished from other gas motors by the employment of a more powerful gaseous mixture, and by its high rate of speed. The explosive mixture is formed from gasoline, and the carburetter, where the mixture is prepared, is shown on the right of the illustration. An engine of 1 horse-power consumes about half a litre of gasoline per hour. The speed is regulated by a very sensitive governor acting on the escape valve, and regulates the number of explosions proportionately to the power required. The ignition is effected by a platinum capsule heated to a red heat by an exterior flame. There are, therefore, no slides or electrical spark used. The lubrication of the principal parts of the motor, which are enclosed in the framing, is done by a lubricator placed on the cylinder. The

engine is started by moving a small handle placed on the fly wheel, and which, as soon as one explosion has taken place, throws itself out of gear. The inventor has aimed at producing a motor of light design so as to be easily transportable. This has been done by reducing the number and weight of the working parts, and it is therefore claimed to be especially adapted for electric lighting. pleasure launches, fire engines, and the propulsion of tramcars. As stated in our issue of the 2nd May, a line is being used in the centre of Vienna, in connection with the Lands and Forests Exhibition, to accommodate a new car driven by one of these motors. The Daimler motor is made with one or two cylinders, and can be worked either by petroleum or gas. In the latter case the carburetter is unnecessary. The motor is manufactured by Messrs. Panhard & Le Vassor, of 19, Avenue d'Ivry, Paris. We are indebted to our contemporary *La Revue Universelle des Inventions Nouvelles* for the above illustration.

IMPROVED COKE CRUSHER.

CONSTRUCTED BY MESSRS. FRANCIS B. WELCH & CO., ENGINEERS, MANCHESTER.

RESEARCH COMMITTEE ON MARINE ENGINE TRIALS.*

(*Continued from page 546.*)

2. TRIAL OF THE S.S. "COLCHESTER."

Steamer.—This vessel is the latest of those built for the Great Eastern Railway Company for carrying their passenger traffic between Harwich and Antwerp. The committee is very greatly indebted to the Great Eastern Railway Company, and especially to Mr. Holden, the locomotive superintendent of the line, and to Captain Howard, the company's marine superintendent, for the facilities which they gave throughout for the carrying on of the trial. The "Colchester," which is driven by twin-screws, is a vessel of 281ft. in length, 31ft. beam, and 15·2ft. in depth. Her gross registered tonnage is 1,160, her net registered tonnage being only 517 tons, the remainder of 643 tons representing space occupied by machinery, seamen, &c. Her draught at Harwich at the end of the trial was 13ft. 7in. aft and 10ft. 6in. forward, corresponding to a displacement of 1,675 tons. The trial was made upon the 9th of November, 1889, on a run from the Humber to Harwich. The ship had been lying in the Humber, where her machinery had received a thorough overhauling by the makers, Messrs. Earle's Shipbuilding and Engineering Company, Hull. Steam was got up on the morning of the 8th November, and the engines were turned round about 3 p.m. on that day. The steamer left her moorings about 3 a.m. on the 9th November, and the trial started at 5 a.m. on that morning. It lasted until 4 p.m. exactly, the boat being taken a little south of the Stour estuary in order to prolong the trial somewhat. The furthest south point was reached at 3 p m. on the 9th November. The engines were stopped about seven minutes during this time to allow the pilot to leave the ship, and they were also slowed down for five minutes about the same time. The counter was read at each of these changes of speed, all of which occurred before 5.40 a.m.

Engines—The "Colchester" is fitted with two compound surface-condensing engines, driving the two screw shafts. The engines are entirely separate, and are placed slightly inclining from the vertical, the space between them being taken up by a condenser which is common to the two. They were built by Earle's Shipbuilding and Engineering Company in 1888-9. The vessel had been on her station running to Antwerp and back twice every week from the end of February to the middle of September, 1889, and had run a total distance of about 16,530 miles during that time; and had undergone her first overhaul at the makers, as already mentioned, during the week before the trial. The engines and boilers therefore were in thoroughly good order. The diameters of the cylinders are 30in. and 57in. respectively. An opportunity has not occurred to gauge them. Their common stroke is 36in. The diameter of all piston rods is 6in., and of all tail rods 4·5in. The cranks of each engine are at right angles, and the high pressure cranks lead. The cylinders are not jacketed. The clearances of the high and low pressure cylinders as given by the owners are 9·39 and 6·23 per cent. The valve gear is of the ordinary link motion type. The surface-condenser contains 3,000 square feet of tube surface in 1,176 tubes, 1in. external diameter, and 9ft. 11⅞in. long over plates. The screw propellers have cast-steel blades and boss; each is 11ft. 6in. diameter, and 20ft. 4½in. pitch, with a surface of 45½ square feet.

Boilers.—There are two iron boilers, each double-ended, 13ft. mean diameter, and 18ft. 3in. long; each boiler having six furnaces of 3ft. 4in. internal diameter. The total grate surface is 220 square feet; the length of each surface on bars being 5ft. 6in. The total heating surface is 5,820 square feet, of which 4·770 square feet is tube surface. There are 784 tubes, 3¼in. external diameter, and 6ft. 9in. long over plates. The total heating surface is therefore 26·5 times, and the tube surface 21·7 times the grate surface. The boilers have been designed to work safely with a pressure of 90lb. of steam, but are ordinarily worked, as during the trial, with a pressure from 5lb. to 10lb. less. There are two double funnels, one for each stoke-hold; the internal diameters of their outer and inner shells are respectively 6ft. 7in. and 5ft. 5in., and the total height of each funnel is 47ft. above the centre of the wing furnaces. The total weight of the engines and boilers, including water in condenser, pipes, and boilers, and all mountings is about 395 tons. The net volume of the boilers is about 4,980 cubic feet.

Duration of Trial.—The duration of trial from start to finish was 11 hours exactly. Deducting the 7 minutes of stop, the running time was therefore 10 hours 53 minutes, or 653 minutes.

Coal Measurement.—The coal was weighed in each stoke-hold by spring balances as before. From 500lb. to 760lb. of coal was put down at one time on each side of each stoke hold. The trial was started with clean floors in each stoke-hold. The time was noted at which each lot of weighed coal was put upon the fire, and no more coal was weighed out until the floor was again

clear. The line of coal consumption plots out as shown in Fig. 7. The fires were not cleaned during the run. The ashes were weighed after the trial was over; but the weight of the ashes given below includes the ash formed while steam was being raised during the time the fires were banked up before the start, and during the two hours' run before the trial actually commenced. The fire-grates were fitted with Henderson's fire-bars, with the object mainly of rendering possible a somewhat large rate of combustion, so as to get the greatest possible duty out of the boilers. The coal used in the forward stoke-hold, and during the first half of the run in the after stoke-hold, was Monk Bretton (Yorkshire) coal. For the second half of the run a mixed coal, chiefly Hucknall and Shireoaks (Nottinghamshire), was used in the after stoke-hold. Coal samples were taken frequently during the run from both stoke-holds, and mixed together, and finally pounded; so as to obtain as representative a sample as possible for analysis. The analysis was made as before by Mr. C. J. Wilson, who gives it as follows:—

	Coal as Used.	Dry Coal.
Carbon	71·89 per cent.	74·08 per cent.
Hydrogen	5·42 ,, ,,	5·66 ,, ,,
Moisture	4·25 ,, ,,	0·00 ,, ,,
Ash	4·08 ,, ,,	4·26 ,, ,,
Nitrogen, sulphur, oxygen, &c., by difference	14·36 ,, ,,	15·00 ,, ,,
	100·00	100·00

The following is an analysis made by Mr. Wilson of a sample of the clinker and ash:—

Loss on ignition (= Carbon)	43·73 per cent.
Mineral matter	56·27 ,, ,,
	100·00

The ash, therefore, contained about 43·7 per cent. of carbon. The calculated calorific value of the fuel as used is 13,280 thermal units, which corresponds to the evaporation of 13·75lb. of water from and at 212° Fahr. The equivalent carbon-value of 1lb. of the fuel as used is 0·913lb. The total coal used was as follows:—

After stoke-hold,	port side	16,020lb.
,, ,,	starboard side	15,426lb.
Forward ,,	port side	15,509lb.
,, ,,	starboard side	15,536lb.
		62,491lb.

This amounts to 95·7lb. per minute, or 5,742lb. per hour, taking the running time of 653 minutes. As a check upon the coal consumption it has also been worked out from a time after the stoppage, at about 5.40 a.m., to the end of the trial; and over this period it comes to 95·9lb. per minute—that is to say, the same as before within the limits of measurement. The weather was very fine during the whole of the trial, but a little foggy towards the end, which made the captain of the steamer reluctant to continue

Digitized by Google

the run longer, as it was originally intended to do. The actual amount of clinker and ash weighed off under the conditions already mentioned was 2,890lb. It may be taken roughly that of this quantity 2,200lb., or 200lb. per hour, was made during the actual run, which is about 8½ per cent. of the total quantity of coal.

Furnace Gases.—A sample of the furnace gases was collected over mercury by Mr. Wilson each hour from each funnel, there being twenty samples in all. The analyses of these samples are given in Tables II. and III. This set of analyses and the corresponding set for the "Tartar" trial are perhaps the most important and complete which have ever been made under such conditions, and merit very close examination. The "mean" figures in the table show that 3·8 per cent. by weight of the dry furnace gases is carbon, from which it follows that, allowing for the combustion of the hydrogen of the fuel, 18·5lb. of dry air passed through the furnace per pound of coal burnt. The chimney temperatures were read in each funnel every quarter of an hour during the whole of the trial, from a mercury thermometer containing compressed nitrogen over the mercury. This thermometer reads up to 860° Fahr., but in a very large number of cases (about three-eighths of the whole) the temperature rose somewhat above the maximum reading of the thermometer. It was obvious from the motion of the mercury that the true temperature was not much above the limit of the thermometer, but of course its exact value is unknown. Assuming that the mean value of these readings was 20° Fahr. above the limit of the thermometer, or 880° Fahr. (which is probably true within an error of 10° either way), the mean temperature in the forward funnel was 828° Fahr., and in the after funnel 842° Fahr., the mean of both being therefore 835° Fahr. The mean chimney draught, measured by U gauges, was 0·38in. of water in the forward, and 0·34in. in the after funnel.

Feed-Water Measurement.—The feed-water was measured in the two tanks, of which details of construction are shown in Figs. 5 and 6. These tanks have been made specially for feed measurement, in a form as adaptable as possible to the conditions of various steamers, and in parts of such a size that they can be readily got down into the engine-room of a steamer and erected and jointed there. It was found possible to put them together in an extremely confined space in the "Colchester," and again in the "Tartar," at a somewhat later date, and it is thought that the details of their construction may therefore be interesting. Each tank held about 2,200lb. of water at 64° Fahr. between the upper and lower cocks. Their contents were carefully tested by weighing water into them when jointed and connected before placing them on board the steamer. Each tank lasted in the "Colchester" about three minutes. The total amount of water used was 468,845lb., over a total running time of 654 minutes. (The last feed tank was finished at 4.1 p.m. instead of 4 p.m.) This amounts to 717lb. per minute, or 43,020lb. per hour, the mean temperature of the feed being 113° Fahr. The continuous consumption of feed water is shown in Fig. 7. The feed pump of one of the engines only was employed to pump throughout, the other pump not being used. All the steam made by the boilers went to the main engines; the steam for the circulating-pump engine, the steering engine, and dynamo engine, and any steam for heating that was required, was taken from the donkey boiler, to which special steam connections were made for the purpose. The water-level was practically the same at the beginning and end of the trial.

Power Measurement.—Indicator diagrams were taken every half hour from each engine. There were thus twenty-two sets of diagrams, or 176 single cards, taken in all. The six indicators used were all made by Messr. T. S. M'Innes & Cairns, of Glasgow, and kindly lent by them to the Committee. These indicators are very simple in construction and handy in use, and their vulcanite sheathing is attended, at sea especially, with much convenience in manipulation. The following are the mean effective pressures in the cylinders in lbs. per square inch:—

Cylinder.	Top.	Bottom.	Mean.
Port, high-pressure	43·34	47·96	45·65
„ low-pressure	13·25	13·58	13·42
Starboard, high-pressure...	38·45	45·68	42·07
„ low-pressure ...	11·68	13·15	12·42

These pressures correspond to the following indicated horse-powers:—

Port engine; high-pressure cylinder.....	490·3	
„ „ low-pressure cylinder	532·2	
		1,022·5
Starboard engine; high-pressure cylinder	457·9	
„ „ low-pressure cylinder	499·8	
		957·2
Total indicated horse-power		1,979·7

The maximum indicated horse-power given by any one set of cards is 2,194·2, which occurred at 10.15 a.m., with a mean speed of 88·6 revolutions per minute, and 86lb. of steam. The minimum indicated horse-power by any one set of cards was 1,699·6, at 5·45 p.m., with a mean speed of 83·2 revolutions per minute, and 73lb. of steam. From the 176 diagrams which were taken during the trial, two mean diagrams have been plotted, one for the two high-pressure and one for the two low-pressure cylinders, and these are given in Fig. 10. The continuous variations of boiler pressure and cylinder mean effective pressures are shown in Fig. 8; and of horse-powers and speeds in Fig. 9.

Speed.—The counters for the two engines were entirely separate. The total number of revolutions made by the port engine was 56,136, and the total number of revolutions made by the starboard engine was 56,857; which totals correspond respectively to 86·0 and 87·1 revolutions per minute. The maximum number of revolutions per minute for any half hour was 89·9 for the port, and 91·7 for the starboard engine; and the minimum number, except when slowed down, was 82·9 for the port, and 84·0 for the starboard engine.

Pressures, &c.—The mean barometric pressure during the trial was 30·6in. of mercury, or 15·0lb. per square inch. The mean boiler pressure was 80·5lb. per square inch by the pressure-gauge in the stoke-hold, and 78·2lb. per square inch by the pressure-gauge in the engine-room. It will be noticed from the diagram (Fig. 8) that the pressure was falling both at the commencement and at the end of the trial. The mean vacuum by gauge was 25·4in. of mercury, corresponding to 2·5lb. per square inch of absolute back pressure. The mean pressure in the receiver of the starboard engine was 8·0lb. per square inch above the atmosphere, and in that of the port engine 8·8lb. per square inch above the atmosphere. The mean initial pressures in the high-pressure cylinders were 64·3lb. per square inch above the atmosphere in the port engine, and 59·4lb. in the starboard engine. The mean back-pressures in the low-pressure cylinders were respectively 4·4 and 4·5lb. per square inch absolute.

Boiler Efficiencies.—The mean rate of combustion in the furnaces was 26·1lb. of coal per square foot of grate surface per hour, or 0·987lb. per square foot of total heating surface per hour. The evaporation was at the rate of 7·49lb. of water per lb. of coal. The feed entered the boiler at a temperature of 113° Fahr., and the temperature corresponding to the mean boiler pressure was 324° Fahr., so that each lb. of steam must have taken up 1,100 thermal units; hence the equivalent evaporation from and at 212° Fahr. was 8.53lb. of water per lb. of coal, or about 9·34lb. per lb. of carbon-value in fuel. The equivalent amount of heat utilised per lb. of coal was 8,240 thermal units, or say 62 0 per cent. of the whole calorific value of the fuel, which percentage therefore represents the actual boiler efficiency. The total calculated calorific value of the fuel burnt per minute was 1,271,000 thermal units. The weight of dry air per lb. of coal, calculated from the furnace gas analyses, works out to 18·5lb., so that the total weight of furnace gases per lb. of coal would be about 19·4lb. Their specific heat may be taken as 0·238, and they have been raised in temperature from, say 55°Fahr., the temperature of the outer air, to 835° Fahr., the temperature of the chimney gases. This corresponds to a loss of 3,714 thermal units per lb. of coal, or 28·0 per cent. of the whole calorific value of the fuel, including the raising through the same range of temperature of the steam formed by the combustion of the hydrogen in the fuel. The loss due to evaporation of the moisture in the fuel works out to 0·4 per cent., and that due to imperfect combustion to 1·3 per cent. These quantities add up to 91·7 per cent. of the whole heat of combustion, leaving a balance of 8·3 per cent., which includes all losses by radiation unaccounted for. The weight of water evaporated from and at 212° Fahr. per square foot of total heating surface was 8·42lb. per hour. The average rate of transmission of heat through the material of the boiler was 8,130 thermal units per square foot of heating surface per hour.

Coal Consumption.—The total coal burnt—namely, 5,742lb. per hour—corresponds to 2·90lb. per indicated horse-power per hour. This is equivalent to 2·65lb. of carbon-value per indicated horse-power per hour.

Engine Efficiencies.—The total indicated horse-power being 1,980, and the total feed water used per hour being 43,020lb., the feed water used per indicated horse-power per hour was 21·73lb. The actual heat received by the feed water per minute was 788,700 thermal units, or 898 4 thermal units per indicated horse-power per minute; which is 62 per cent. of the whole heat of combustion. The absolute engine efficiency was 10·7 per cent.

Total Efficiency.—The combined efficiency of the boilers and engines, or ratio of the heat turned into work to the total heat of combustion of the fuel, was 0·62 × 0·107, which is equivalent to 6·6 per cent.

Steam from Indicator Diagrams.—The following are the results of measurements made upon the indicator diagrams taken to ascertain the proportion of steam accounted for by them. The actual weight of feed water used per revolution was 8·28lb:—

Proportion of Steam accounted for by Indicator Diagrams.	Lbs. per Revolution.	Percentage of Total Feed.	Percentage present in Cylinder as Water.
	Lbs.	Per Cent.	Per Cent.
Steam present in high-pressure cylinder, port engine, after cut-off, when the pressure was 51lb. per square inch above the atmosphere	3·11		
Steam present in high-pressure cylinder, starboard engine, after cut-off, when the pressure was 51lb. per square inch above the atmosphere	2·88	71·7	28·3
Steam present in low-pressure cylinder, port engine, near end of expansion, when the pressure was 7lb. per square inch below the atmosphere	2·19		
Steam present in low-pressure cylinder, starboard engine, near end of expansion, when the pressure was 7lb. per square inch below the atmosphere	2·20	53·0	47·0

Speed of Vessel.—The following notes from the log book of the ship may be of interest:—

	Time.	Distance in Nautical Miles.
Left Hull Roads	3·15 a.m.	... 0
Spurn Light	4·40	... 24
Dudgeon „	7·45	... 54
Cromer „	9·5	... 75½
Cockle „	10·35	... 97
Corten „	11·15	... 108
Shipwash „	1·25 p.m.	... 140
Sunk „	2·20	... 151
Long Sand Head Light	2·40	... 158½
Cork Light	4·0	... 173
Parkeston Quay	4·35	... 178½

The mean speed between Dudgeon and Cork Lights, which includes nearly the whole of the trial except that portion when the vessel was slowed down and stopped, was therefore 14·4 knots.

The "Colchester" is a vessel built rather to attain a maximum of power and speed over a short journey than a maximum of economy. Looked at from this point of view, it may be interesting to compare the relation between power developed and the size of the machinery in her case, and in those of the other steamers tested. The net volume of her boilers is about 4,980 cubic feet, or at a rate of 2·5 cubic feet per indicated horse-power. This ratio in the case of the "Meteor," "Fusi Yama," and "Tartar" is respectively, 2·7, 4·53, and 4·34 cubic feet per i.h.p.

(To be continued.)

THE INSTITUTION OF CIVIL ENGINEERS.

The annual general meeting of corporate members—"to receive and deliberate upon the Report of the Council on the state of the Institution, with the annual statement of the accounts, and to elect the Council and officers for the ensuing year"—took place on Tuesday, the 3rd inst., Sir John Coode, K.C.M.G., the President, being in the chair.

This meeting was held on the sixty-second anniversary of the incorporation of the Institution by Royal Charter. At that time the number of members was 156, and the gross annual receipts were £447. At the close of the past financial year the number of members was 5,872, and the gross receipts for the twelve months amounted to £22,478. This increase—thirty-seven-fold in numbers and fifty-fold in amount—sufficiently indicated the position which the Institution had taken in connection with the profession it was designed to promote. It should always be borne in mind that a large rate of increase was by no means desirable. There was no object, however, in limiting the numbers, as was the custom in some exclusive bodies, for the Institution had always opened—and it was hoped always would open—its doors to all engineers who had an honest title to be entered on its register; but it refrained from augmenting its numbers by the admission of persons who were merely attracted to it for their own advantage. Above all things, the Council desired it to be understood that membership in the Institution should be a real guarantee of the professional standing, and (as far as possible) also of the personal character, of those on whom it was conferred. For these reasons, the Council repeated the recommendation, often previously made, that every member should take care not to attach his signature to any proposition-paper unless fully satisfied as to the truth of the representations it contained and as to the general eligibility of the candidate.

During the past year there were elected three honorary members (Sir Henry Bessemer, F.R.S., Sir William Thomson, LL.D., F.R.S., and General Edward Frome, R.E.), thirty-two members, 263 associate members, and three associates, while the name of one member was restored to the list. On the other hand, 138 names had been removed from the register, eighty-seven of which were losses by death. Among the latter, the Council recorded with regret the names of three honorary members—the King of Portugal, Dr. John Percy, F.R.S., and General Edward Frome, R.E., who died shortly after his election. The roll of the Institution therefore showed a net increase of 164, the number of members of all classes (irrespective of students) being now 4,903. This represented an increase at the rate of about 3½ per cent. per annum. Owing to more stringent regulations as to the admission of students, there had been a decrease of twenty in the number of that class. The admissions had included 156 students, and one was restored to the list, while seventy-three had been elected associate members and 104 had passed out of the list.

At the ordinary meetings, papers on important constructive engineering works had been read, and also on many branches of mechanical and electrical engineering. It was hoped that some branch of metallurgy might have been brought forward, but in that hope the Council had been disappointed. It was, however, confidently believed that the omission would be made good next session. For two of the papers the Institution was indebted to Mr. Lyster, Member of Council, and to Sir Frederick Bramwell, Bart., D.C.L., F.R.S., Past President. In conformity with long-established usage, these communications were not taken into consideration in the adjudication of the premiums.

Since the last annual meeting four volumes of Minutes of Proceedings had been issued. The Council trusted that the members would continue to contribute to this part of the work of the Institution, as being that which was of the greatest permanent importance. It was intended, shortly, to issue a pamphlet of about 60 pages, enumerating those public educational establishments in the British dominions which included special preparation for the engineering profession.

The abstract of receipts and expenditure showed, on the credit side, income £17,677 13s. 10d.; capital (that was admission fees and life compositions), £3,794 14s.; trust fund receipts, £1,005 6s. 9d. (including the Crampton Bequest of £500 and the Trevithick Memorial Donation, £100 0s. 9d.), making a total of £22,477 14s. 7d. On

Digitized by Google

the other side of the account, the general expenditure had been £14,696 6s. 3d.; the investments on account of capital, £6,090 19s.; and payments or investments of trust funds, £1,049 2s. 4d. At present the Institution investments in Consols, Metropolitan Board of Works Stock, and Railway Debenture Stocks aggregated £43,500; the freeholds of the three contiguous houses in Great George Street, £40,000; the Whitworth legacy, £5,400; and trust funds, £15,286 0s. 10d., making a total of £104,186 0s. 10d.

In conclusion, the Report referred to the visit, last summer, to Europe, of a representative body of members of the American Societies of Civil, Mining, Mechanical, and Electrical Engineers, which their Institution had the honour of entertaining for six days. Many and various were the means which the Reception Committee took to arrange for the amusement and recreation of the visitors. On the whole, the visit might be considered to have been a great success, and was one full of pleasant memories for the hosts.

The adoption of the Report was moved, seconded, and carried, and it was ordered to be printed in the Minutes of Proceedings. Cordial votes of thanks were then passed to the President, to the Vice-Presidents, and other members of the Council, to the auditors, to the secretaries and staff, and to the scrutineers.

The ballot for Council resulted in the election of Sir John Coode, K.C.M.G., as President; of Mr. G. Berkley, Mr. H. Hayter, Mr. A. Giles, M.P., and Sir Robert Rawlinson, K.C.B., as Vice-Presidents; and of Mr. W Anderson, D.C.L., Sir Benjamin Baker, K.C.M.G., Mr. J. Wolfe Barry, Mr. E. A. Cowper, Sir Jas. N. Douglass, Sir Douglas Fox, Mr. J. Clarke Hawkshaw, M.A., Mr. C. Hawksley, Sir Bradford Leslie, K.C.I.E., Mr. G. Fosbery Lyster, Mr. J. Mansergh, Mr. W. H. Preece, F.R.S., Sir E. J. Reed, K.C.B., F.R.S., M.P., Mr. W. Shelford, and Mr. F. W. Webb, as other members of the Council.

The session was then adjourned until the second Tuesday in November, at 8 p.m.

The following is a detailed list of the awards made for communications submitted during the past session:

FOR PAPERS READ AND DISCUSSED AT THE ORDINARY MEETINGS.

1. A Telford Medal and a Telford Premium to John Robinson, M.Inst.C.E., for his paper on "The Barry Dock Works, including the Hydraulic Machinery and the Mode of Tipping Coal."
2. A Telford Medal and a Telford Premium to Charles Ormsby Burge, M.Inst.C.E., for his account of "The Hawkesbury Bridge, New South Wales."
3. A Telford Medal and a Telford Premium to Frederick Thomas Granville Walton, C.I.E., M.Inst.C.E., for his description of "The Construction of the Dufferin Bridge over the Ganges, at Benares."
4. A Telford Premium to Sydney Walker Barnaby,* M.Inst.C.E., for his paper on "The Screw Propeller."
5. A Telford Premium to William Henry Wheeler,† M.Inst.C.E., for his paper on "Bars at the Mouths of Tidal Estuaries."
6. A Telford Premium to James Price, Jun., B.E., M.Inst.C.E., for his account of "Lough Erne Drainage Works."
7. The Manby Premium to William Paul James Fawcus and to Edward Woodrowe Cowan, Assoc.MM.Inst.C.E., for their joint paper descriptive of "The Keswick Water-Power Electric Light Station."

FOR PAPERS PRINTED IN THE PROCEEDINGS WITHOUT BEING DISCUSSED.

1. A Telford Premium to Charles Hopkinson, B.Sc., M.Inst.C.E., for his paper on "Hydraulic Packing-Presses."
2. A Telford Premium to Herbert Gurney Sheppard, Assoc.M.Inst.C.E., for his paper on "The Reclamation of Lake Aboukir, near Alexandria, Egypt."
3. A Telford Premium to Wilfrid Airy, B.A.,‡ M.Inst.C.E., for his papers "On the Action of Quicksands" and on "The Probable Errors of Surveying by Vertical Angles."

FOR PAPERS READ AT THE SUPPLEMENTAL MEETINGS OF STUDENTS.

1. The Miller Scholarship to Charles Frewen Jenkin, B.A., Stud.Inst.C.E., for his paper on "Some Applications of Electricity in Engineering Workshops."
2. A Miller Prize to Charles Henry Wordingham, A.K.C., Stud.Inst.C.E., for his paper on "Telephonic Switching."
3. A Miller Prize to Alfred Ernest Young, Stud.Inst.C.E., for his account of "The Deflection of Spiral Springs."
4. A Miller Prize to Lucien Alphonse Legros, Stud.Inst. C.E., for his paper on "Economy Trials of a Compound Mill-Engine and Lancashire Boilers."
5. A Miller Prize to Frank Paul Reynolds, A.K.C., Stud.Inst.C.E., for his description of the "Roof over the Carlisle Markets."
6. A Miller Prize to George Hale, Stud.Inst.C.E., for his description of the "Hydraulic Station and Machinery of the North London Railway at Poplar."
7. A Miller Prize to George Harrison Sheffield, Stud. Inst.C.E., for his paper on the "Principles of Iron Foundry Practice."

It has been determined to print the first three students' papers, either in whole or in part, in the Minutes of Proceedings.

* Has previously received a Watt Medal and a Telford Premium.
† Has previously received Telford Premiums.
‡ Has already received Telford and Manby Premiums.

THE AMERICAN SOCIETY OF ENGINEERS.

(From our New York Correspondent.)

(Continued from page 530.)

AT the third day's meeting of the Cincinnati meeting of the American Society of Mechanical Engineers, held on the 15th of May, Mr. R. C. Carpenter, of Lansing, read a paper on "The Comparative Test of a Hot Water and a Steam Heating Plant." The test was undertaken to decide whether the better method of heating green houses was with low-pressure steam or with hot water. Two buildings, each 50ft. by 19½ft., were erected side by side, extending north and south. The heaters were made by the same manufacturer, and have the same amount of heating surface, grate, and external dimensions. The total heating surface was 45·18 square feet and the grate 1·89 square feet. In the steam house the heating surface was 200 square feet, the total space 6,174 cubic feet, and the ratio of heating surface to glass 1 to 5½. In the hot-water house the heating surface of the pipes was 275 square feet, and the ratio of the heating surface to the glass surface 1 to 4. The pressure on the hot water system was maintained uniform by an expansion tank 12in. diameter and 18in. high, located 18ft. above the water in the lowest return. The tests began December 21st, and lasted until March 1st. Coal was fired in 25lb. lots at 6 a.m., 4 p.m., and 9 p.m. Temperatures were taken at 6 a.m. and 9 p.m. inside and outside, and the maximum and minimum daily readings were recorded. The average coal consumption and temperatures are given in the following table:—

	Dec.	Jan.	Feb.
Outside temperature, 6 a.m. ...	31·8	27·7	22·0
" " 9 p.m. ...	35·1	27·2	
HOT-WATER HOUSE.			
Average temperature, 6 a.m. ...	54·9	54·1	54·4
" " 9 p.m. ...	60·3	54·8	56·0
Coal per 24 hours in lbs.	75·0	90·3	99·1
STEAM HOUSE.			
Average temperature, 6 a.m. ...	53·9	52·5	54·1
" " 9 p.m. ...	54·9	53·8	53·5
Coal per 24 hours in lbs.	93·2	112·1	121·4

So far as variation or range of temperature is concerned the two heaters were practically the same, and in no case did this exceed 4° when the fire was carefully attended to.

Mr. Emery objected to the paper as not giving any general data on which to base a comparison as to the relative advantages of the two systems, as hot-house practice was very different from house heating, to which the systems were generally applied.

Mr. Mason said that the results might have been predicated from the method of fitting up and the apparatus used.

The next paper was by the same author, on "Notes on Kerosene in Steam Boilers," and gave the author's experience on removing scale by the use of kerosene, by which scale ⅜in. thick was entirely removed from a battery of boilers. The kerosene seemed to work in between the shell and the scale in such a manner as to loosen large flakes of the scale, sometimes fully 1ft. in length. The amount used was two quarts for a cylindrical tubular boiler 4ft. in diameter by 12ft. long, each week, and three quarts in a 5ft. boiler. The oil was introduced into the suction side of the feed pump. The cost was not over $2 per annum per boiler. The water used contained 325 parts of solid matter to 1,000,000, of which 206 parts were $CaCO_3$, 78$MgCO_3$, and 22 parts $FeCO_3$, with traces of sulphates and chlorides of potash and soda.

The next papers presented were on shaft governors, and were read together. They were "A Use for Inertia in Shaft Governors," by Mr. E. J. Armstrong, of Syracuse, New York; "A Governor for Steam Engines," by Mr. Jesse M. Smith, of Detroit, Mich.; and "The Effect of an Unbalanced Eccentric or Governor Ball on the Valve Motion of Shaft Governed Engines," by Mr. John E. Sweet. In the first paper the author states that inertia, instead of being a disturbing element, can be, and is, made the reverse, even to performing the function of a dash pot. Any considerable friction in a governor becomes a serious fault, but a small amount, such as is present in nearly all governors under the most favourable circumstances, would seem to be rather an advantage; the friction and inertia of the valve and its connections are usually sufficient to keep up a slight vibratory movement in the governor, and when this is the case the fly-weight will move very easily if it only moves slowly, the friction coming into full effect should the weight attempt a more rapid change of base. Mr. Smith's paper was a description of a governor designed and applied in 1883.

The next paper was by Mr. W. W. Bird, of Worcester, Mass., on "An Open Mercury Column for High Pressures." The object of the author was to design an open column which would read to 200lb. per square inch; it should be sufficiently accurate for engineering purposes, cheap, and, if possible, should provide for taking readings at one convenient point. In Fig. 1, A A is a column of small iron pipe made in four sections, each of sufficient length to give 50lb. pressure. *a*, *b*, *c*, and *d* are overflow pipes which can be closed off by the cocks shown. These pipes discharge in the cistern F, from which the mercury pump M takes it to and discharges it into the column A A again. The bottom of the column is connected to the glass tube B long enough to indicate 50lb. To the top of this tube is connected a water pump W and a flexible tube C connecting with the gauges G G. The stop cocks *a*, *f*, and *e* being open, mercury is pumped into A and B until it overflows at *a*. On the glass tube this gives the zero point. Cock *e* is closed and water pumped in to fill the top of B, C, and D. By pumping in more water the level in B can be lowered to any desired amount, *a* being constant; and by sliding D along the upright E E the water column can be balanced. Closing *a* and opening *b* will add 50lb. to the reading on the glass scale B, and in this way the pressure to 200lb. or over, if desired, can be read in the length of the glass tube B very conveniently.

The next paper was by Mr. George I. Alden, of Worcester, Mass., on "An Automatic Absorption Dynamometer." The dynamometer is a friction brake, in which the pressure causing the friction is distributed over a comparatively large area, thus giving a low pressure between the rubbing surfaces. The pressure is produced by the action of water from the town main. Enough water is allowed to pass through the machine to carry off the heat due to the energy absorbed. The rubbing surfaces are finished smooth, and run in a bath of oil. A valve, operated by the slight angular motion of the dynamometer, varies the supply of water, and consequently the pressure between the frictional surfaces, thus securing automatic regulation. In Fig. 3, A is an iron disc keyed to the crank-shaft B. The sides of this disc are finished smooth, and each side has one or more shallow radial grooves, as shown at X, Fig. 2. The outer shell consists of two pieces of cast iron C C, bolted together, and held at fixed distances apart by the iron ring D of the same thickness as A, and by the edges of the copper plates E E. Each of these plates at its inner edge makes, with the cast-iron shell a water-tight joint by being spun into a cavity in the iron and held by driven rings F F. Water is admitted between the cast-iron shell and the copper plates at G, and passing to the opposite compartment through passages shown at O is discharged through a small outlet at H. The chamber M N N is filled with oil, which finds its way along the grooves X. The shaft is free to revolve in the bearings of the cast-iron shell C C. The shell has an arm carrying weights as shown in Fig. 2. This arm has its angular motion limited by the stop P and Q. The regulating valve is simply two tubes one inside the other, one being stationary and the other revolved by the movement of the brake. Holes parallel to the axis allow the water to pass into the brake. Figs. 5 and 6 show a longitudinal and a cross-section of the valve. The dynamometer is operated as follows:—The chamber N N M is filled with oil, and weights are suspended from the arm to give the desired load. The engine is started up, and when up to speed a valve is opened in the water-pipe, admitting water to the automatic valve V, Fig. 3. Water passes through this valve and forces the copper plates against the sides of the revolving disc A, causing sufficient friction to balance the weights upon the arm. This motion operates the automatic valve regulating the friction on the disc. The arm is found to stand midway between the stops with only slight and slow vibration, so that there is no sudden vibration of the arm, and the load is practically constant.

The fourth session of the Convention was held on Wednesday evening at 8 p.m. The following papers on chimneys and draft were read:—"Pictet's Treatment of Chimney Draft" and "The Mechanical Theory of Chimney Draft" by Mr. J. B. Webb; "Chimney Draft," by

Digitized by Google

Mr. De Volson Wood, and "Tests of Recent Formula for Chimney Draft," by Mr. William Kent. The next two papers were by Mr. De Volson Wood, on "Graphic Representation of Thermodynamic Quantities" and "Test of a Refrigerating Plant." The secretary presented for Professor R. H. Thurston a paper on "Hirn and Dwelshauver's Theory of the Steam Engine, Experimental and Analytic," which was mainly historical.

Mr. George H. Barrus, of Boston, Mass., presented a paper on "A Universal Steam Calorimeter." The apparatus is represented in Fig. 7. The principal parts of the instrument consist of a chamber A, or "drip-box," as it is called, and the "heat-gauge," consisting of the orifice I and the two thermometers M and N. The instrument is connected to the main steam pipe G, which carries the steam to be tested, by means of the perforated pipe F, and this pipe extends across the full diameter, in order to obtain a sample of the steam tested. The orifice I opens into a pipe which is in free communication with the atmosphere, the opening being about $\frac{1}{8}$in. in diameter. The parts below the plate R are entirely insulated from those above by the use of some non-conducting material, as it is necessary to prevent any transfer of heat from the high to the low-pressure side of the plate. The range of the "wire drawing" part of the instrument or "heat-gauge" is from 3 to 4 per cent. of moisture with steam at 80lb. It is unnecessary to use the drip-box unless the quantity of moisture is in excess of 3 per cent. The unions P and Q are, therefore, made interchangeable, and a preliminary trial will show whether A should be used or not. In the complete apparatus the condensed water from the drip-box is drawn off by means of the valve D into a bucket on scales or through a condensing coil. This quantity is of course to be added to that passing through Z to determine the moisture in the steam. The amount of radiation must be allowed for also. In order to compute the amount of moisture from the loss of temperature shown by the heat-gauge the number of degrees of cooling of the lower thermometer is divided by a coefficient representing the number of degrees of cooling due to 1 per cent. of moisture. This coefficient depends upon the specific heat of superheated steam, which, according to Regnault's experiments, is 0·48. The author's experiments show that this quantity is not constant, but varies from 0·42 to 0·51, and it seems that the specific heat is more or less constant until the temperature by the lower thermometer approaches the point of saturation for the low-pressure steam, while beyond this point the specific heat rapidly increases.

Thursday, the 15th of May, was the Excursion Day. A special train was furnished by the Cincinnati, Hamilton, and Dayton R.R., and a party numbering nearly three hundred went to Hamilton, Ohio, on a visit to the Niles Tool Works. This is one of the largest manufacturing establishments of machine tools in the country. The establishment is rapidly increasing in size, and is equipped with the best appliances for rapidly producing machine tools of all descriptions.

On returning to the city the members were entertained at a reception in the Art Museum in Eden Park, which contains one of the finest collections in the United States.

The last session was held on Friday morning. The first paper was a short but interesting one by Mr. D. K. Nicholson, of the Pennsylvania Steel Company, of Steelton, Pa., on "Heating Furnaces." A Siemens furnace probably required, he said, less repairs than any other kind of reverberatory furnace. The gas and air do not unite until they have reached the hearth. By the time the flame reaches the outgoing ports it is pretty well spent, and does little injury to the brickwork. The bricks are not subjected to the cutting action of flames as in a coal furnace. It is necessary to work the furnace with an outward pressure when it is charged, to fill the furnace with flame and keep the cold air from drawing in at the doors. In the Smith furnace the regenerators are built at the ends of the furnace. The checkers are entirely open at the top, and on a level with the bridge of the furnace, which is at the same time one wall of the gas chamber. This furnace is generally used for quick heating. The advantages of it are: Cheapness, the ease with which the checkers can be taken out and cleaned, and that the bottom of the conduits and chambers are so little below the surface that they are not likely to become choked with water in low ground. The gas will probably come into the furnace under less pressure than in an ordinary Siemens furnace unless the gas pipe from the top of the producer stack is correspondingly higher. To do good and careful heating the bottom of the furnace must have plenty of attention. With good fire sand and care there is no trouble in maintaining a clean hard bottom gradually sloping towards a tap-hole at the back of the furnace midway from the end.

In heating high carbon steel the metal must be gradually brought up to a working heat. To charge cold steel of high carbon into a warm furnace is disastrous to the metal. A very fine steel, not too high in carbon, will scale off in sheets, while the scale from high carbon steel will break up into fine powder as it comes off. This can be more readily seen under the hammer than the rolls. Gas which contains steam oxidises the steel, and makes a good deal heavier scale, ordinarily 1·25 to 2 per cent. on ingots charged hot. The furnace crown that gives the most satisfaction is a roof that dips about 5 degs. at each end for one quarter the whole distance, and then is straight across, with the necessaryarch sideways for support. The height of the crown for cold metal is generally from four to five times the thickness of the piece.

Too high a temperature in the furnace renders the metal unfit for hammering or rolling. This may be remedied, partly at least, by lowering the temperature of it and again heating it to the right degree. At its best, however, the metal is treacherous, and on any account it should not be used where much depends on strength. Vertical or pit furnaces are only used to reheat ingots brought to them soon after being cast. These furnaces save labour, but are not equal to the horizontal furnace for heating the ingot evenly. Their greatest trouble is to get rid of the cinder, especially with low carbon steel. Tapping through the bottom is the best way, if the tap-hole could be easily opened and closed. The material is not likely to roll so well from a soaking pit as that which is heated in a furnace with fuel supplied to it. The inside is softer than the outside, and throws more strain on the outside while being hammered or rolled than its share. In ordinary running at least 90 per cent. of the ingots from the Bessemer could be cared for by soaking pits, which is a considerable saving of fuel, labour, first cost, and practically no repairs.

The next paper was by Mr. H. H. Suplee, of Philadelphia, on "Equilibrium Arch Curves," in which he presented the method of Mr. Thomas J. Lovegrove for determining the shape of the equilibrium curve. The method described a ready means by which the curve could be laid down, and the author showed by models that an arch made in this way with blocks of wood for voussoirs would stand, while a semi-circular arch of the same size would fall. In arches built upon equilibrium curves, with joints at all points normal to the curve, no bending moment or tendency to open at the joints can occur, and the material is subject to compression only as is the case in a vertical wall. The theory of the "middle third," which is sometimes opposed to the use of equilibrium curves, does not properly apply at all under the above conditions, as it was deduced entirely from conditions which only obtain when the joints are not normal to the equilibrium curve. Instead of drawing an arch to a curve selected arbitrarily, and then attempting to investigate the position of the curve which its load may produce, the curve should first be drawn from the height, span, and load given, and then any desired form which will include this curve within its figure may be used with safety. For sewers and for the construction of subways the equilibrium curve is by far the strongest and most economical, and objections against its appearance to the eye do not hold.

The next paper was by Mr. Thos. C. Clarke, on the Kinzira Viaduct, built in 1882. After describing the viaduct, method of construction, &c., the author gave illustrations of a section taken from one of the Phœnix columns, showing that no corrosion had taken place in the interior of the column.

Professor J. Burkitt Webb presented a paper on "Length of an Indicator Card," which was a continuation of the paper presented by him at the last meeting.

The next paper was by Professor Jacobus, on "Influence of Steam Jackets of the Pawtucket Pumping Engine." His conclusions are: (1) The effect of jackets on the form of expansion curves of both the high and low pressure cylinders is so small that the errors involved in the most accurate measurements of the indicator diagram make it impossible to show any difference in the laws governing the same; (2) the economy of the plant when working under the three sets of conditions is about 1·7 per cent. in favour of using the flue reheater, and 2·5 per cent. in favour of using both jackets and flue reheater, over that obtained when neither the flue reheater or jackets are used: the duty when both jackets and flue reheater were in use was 121,560,000 ft.-lb. per 100lb. of coal; (3) there was very little re-evaporation during expansion in either the high or low pressure cylinder, the average for all the tests being 0·4 per cent. for the high-pressure cylinder, and 2·9 per cent. for the low-pressure.

The last paper of the session, on "The Effective Area of Screws," by Professor Jacobus, consisted of some deductions made from the tests of two tug boats, and compared the results with those obtained by Professor Denton on the "Homer Ramsdell" and the "Bergen," as presented at the last meeting of the Society.

At various times during the different sessions of the meeting a number of topical queries were taken up, but there was little of interest in the discussions.

The Committee appointed to memorialise Congress on the establishment of a Government Bureau of Mechanical Standards, reported that a Bill had been drafted, presented in Congress, and had been referred to the Committee on Patents, which had promised a favourable report, and the matter there rested.

The usual resolutions of thanks were passed, and the meeting adjourned to meet at the call of the Council in November, probably in Richmond, Pa.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 10th June, 1890.

Iron.—The iron market is gradually giving way under the influence of unfavourable reports from abroad and the certainty that coal will be cheaper in the second half of the year. The Paris merchants readily accept 152s. a ton for bars and 154s. for joists. But even these prices are not sufficient to tempt buyers to deal beyond the bare needs of the moment. A weak tone pervades the markets of the provinces. Merchants who have considerable stocks in hand are growing alarmed, and by pressing their goods for sale they have weakened confidence and checked the current of business. In the Meurthe-et-Moselle 56s. for forge pig and 64s. for foundry are the maximum prices now obtainable. From all the other ironmaking districts unfavourable reports have been received. Everywhere the demand is feeble and diminishing, and prices for finished iron and steel are constantly giving way. Practically nothing is now being done on export account. The Longwy Comptoir is buying largely of German blast furnace coke at greatly reduced prices.

Coal.—The Paris coal market is very quiet, as is usual at this time of the year. In the North production is being pushed to the utmost to make up for the interruption caused by the recent strikes and to profit by present prices, which it is evident cannot be long maintained. A significant fact in this relation is the purchase of 50,000 tons of German coke at a price that is some 20 per cent. below those now current for French produce. The labour disturbances in the Centre and the South have come to an end, and the output of the pits is now but little restricted in those districts. Several of the German delegates at the recent Miners' Congress at Joliment are now in the North of France seeking to promote the project of an International Miners' Union.

Centralisation of Industry.—Another step in the centralisation of industry (a system that seems to be growing in favour) has been made here by forming a central Comité des Industries Nationales de la Soie et de la Laine. This *comité central* represents, to start with, nine departmental associations—four from the silk industry existing at Lyon, Saint-Etienne, St. Chamond, and Calais, and five from the woollen industry existing at Roubaix, Tourcoing, Reims, Fourmies, and Paris. M. Georges Berger, Deputy for the Seine, has been elected president.

Malting Barley.—At the Brewers' Congress held at Lille last week the annual production of barley in France was stated, in round numbers, to be 50,000,000 bushels, an average of 50 bushels per hectare (20¼ bushels per acre). The colony of Algeria produces some 55,000,000 bushels. According to M. Dubernard, the chemist, a good malting barley should contain a maximum quantity of starch with a minimum of nitrogenous organic matters; it should have but little husk, show a farinaceous fracture, and hold a sufficient quantity of phosphoric acid and potash to produce a good fermentation, and consequently a good yeast. To obtain these qualities M. de Geyter recommended a careful selection of seed, and the use of a manure rich in phosphates and as free as possible from nitrogenous matters.

The Paris Metropolitan Railway.—For a good many years past many schemes have been proposed for a city railway in Paris, but on examination it has been found that none of these have been of a sufficiently practical nature. Plans have been made out by M. Ives Guyot and M. Eiffel, which, it is thought, will be found acceptable. According to the present plans, there will be a central line from Puteaux to the Gare de Lyon, by way of the Arc de Triomphe, the Place de l'Opéra, Place du Château d'Eau, and Place de la Bastile, with a second line branching off from the Place de l'Opéra towards the Gare d'Orléans and the Gare de Lyon, and running for some distance parallel to the Rue de Rivoli. In addition to these two main lines, there will be two branch lines, one of which will connect the Northern railway terminus with the Place de l'Opéra, and the other with the Central Market. It is not proposed to ask the State either to make a grant or a guarantee in connection with the railway, the whole of the cost being borne by the companies of the Nord, the Est, the Paris-Orléans, and the Paris-Lyon-Méditerranée.

BERLIN, 9th June, 1890.

Iron.—The languor of the markets in Western Germany is beginning to tell on the trade of Upper Silesia. The animation of last week has in large measure disappeared. Buyers are holding back, in expectation of a considerable reduction in prices when the syndicate meets next week. That this expectation is likely to be fulfilled is shown by the readiness of the merchants to accept offers several shillings a ton below the syndicate minimum. As all manufacturers have plenty of work in hand for several months to come, there is no anxiety for the near future. The Berlin trade is far from active. Joists are in fairly good demand, but buyers haggle long over prices. Here as elsewhere founders are not only very busy on old contracts, but are encouraged to maintain their prices firmly by a steady current of fresh orders. Engineering firms, especially makers of machinery, have plenty to do in the present and bright prospects in the near future.

German Iron Abroad.—The returns of the export trade in German iron for the month of April compare favourably with those for March, the total being 71,393 tons, against 68,413 tons; but there is a heavy falling-off relatively to the same month of last year, which gave a total of 93,095 tons. The following classified statement of the trade of the first four months shows in what directions shrinkage has taken place, the figures in parentheses representing the quantities in the corresponding portion of 1889:—Pig iron, 45,530 (66,212) tons; old and scrap iron, 9,570 (11,814) tons; half-wrought iron and steel, 4,558 (7,667) tons; finished iron and steel (angles, bars, and plates), 67,024 (103,878) tons; wire, 36,484 (60,162) tons; wire nails, 11,365 (17,279) tons; rails, 41,933 (34,754) tons; other railway iron, 19,574 (17,548) tons; heavy castings, except ordnance, 7,635 (4,959) tons; and other manufactured goods, except machinery, 39,761 (36,986) tons. Total, 283,434 (361,259) tons. It will be observed that the falling off is particularly heavy in finished iron and steel, and in wire and its derivative, wire nails. The quantities of wire and wire nails shipped to Great Britain in the four months were 11,603 tons for the former and 3,731 tons for the latter.

Metals.—There is a steady though not strong current of business in metals, and the markets continue to be characterised by an upward tendency. To what this tendency is due it is not easy to discover. It seems to arise solely out of the speculative operations which are forcing up the prices of copper. The latter metal constantly advances under the influence of these "bulling" transactions, and tin and lead are firmer in sympathy. Spelter is itself the object of speculative operations, and moves slowly upward. The W. H. brand is quoted as high as £26.

The Foreign Coal Trade.—In the present circumstances of the coal markets, when the conditions of trade have turned against the coal producers, and prices are rapidly declining, the customs returns showing the movements of the foreign trade in coal in the first four months of the current year are specially interesting, because the existing state of things is largely due to the changes which have taken place in that trade. These returns show an increase, relatively to the corresponding period of last year, of 27·6 per cent. in the imports, 3,427,836 tons, against 2,680,465 tons, and a decrease of 7·2 per cent. in the exports, 3,081,853 tons, against 3,321,805 tons. These statistics, considered in conjunction with the effects of the calm which has overspread the iron trade, justify the attitude of consumers, who, in anticipation of much lower prices, refrain from purchasing beyond the bare needs of the moment.

German Industry in La Plata.—The Government of La Plata recently held a competition for a considerable quantity of machinery for hydraulic works in the port of La Plata, including steam engines, boilers, pumps, accumulators, compressed air pipes, cranes, elevators, capstans, and a floating rotary crane. Among the makers competing were Sir W. G. Armstrong, Mitchell, & Co., Limited, Newcastle on-Tyne, and Mr. G. Luther, Brunswick. The decision was in favour of the latter, who has in consequence received the order.

An Electrical Testing Station.—An electro-technical testing station for North Germany has just been established at Magdeburg, on the lines of the similar institution at Munich. Experiments and tests for public officials and private individuals will be there conducted, to enable them to gain a clear idea of the cost and practicability of electrical undertakings, and the opportunity will be afforded to electrical works to have their machines, apparatus, &c., tested. A well-known electrician —Dr. M. Krieg, editor of the *Elektrotechnisches Echo*—is chief of the station.

Sheep Shearing Machines.—An attempt was recently made to introduce from England into Germany sheep shearing machines working by hand or steam power. A trial shearing was conducted by an English shearer, with a Wolseley shearing machine with twenty-four shears, at the Congress of Pomeranian Wool Growers in Stargard, but it was a failure. The machine in question could be worked by a traction engine or by a steam engine. After an operation lasting uninterruptedly for an hour and a half, the lamb experimented upon emerged from the hands of the shearer in rather a damaged condition. After this result there does not appear to be much prospect of the machine being introduced into Germany.

German Fisheries in the North Sea.—The German deep sea fisheries in the North Sea are slowly but steadily growing. From the official returns it appears that on the 1st of January, 1890, there were 440 fishing vessels in the German Empire, exclusive of coasting vessels, against 440 in 1889, and 425 in 1888. The number of steamers increased more rapidly than the total of both sailing vessels and steamers. Of the latter there were only six at the beginning of 1888, ten in 1889, and eighteen in 1890. It is thus seen that steam is beginning to play an important part in fishing. The vessels were divided among the several States on the 1st of January last as follows:—Prussia, 262 (12 steamers); Oldenburg, 2; Bremen, 4 (2 steamers); and Hamburg, 177 (4). The regular crews numbered 1,161 hands, as compared with 1,641 in 1889, and 1,539 in 1888.

The Breslau Machinery Market.—The twenty-seventh international machinery market opens at Breslau to-day. The exhibits are said to be exceptionally good, nearly every firm of note in Germany and many foreign manufacturers being represented. As a collection of agricultural machinery, the Breslau Exhibition could hardly be surpassed.

The Glass Bottle Trade.—In consequence of the forty-four glass bottle makers having formed themselves into a "ring," and raised the price of bottles 10 per cent., the principal wine merchants have formed themselves into a syndicate to establish new works for the manufacture of such bottles.

VIENNA, 9th June, 1890.

The Iron Market.—The stagnation which was visible for a short time in the iron market has entirely disappeared. Last week large transactions took place, and new increases of prices are to be noted. Tinned sheets increased by 2fl. per 100 kilog. In the Hungarian market also the situation has become better, and pig iron especially is in good request. Rolling mills have as much as they can do to complete the old orders; but during the last week or two they received a large number of new ones. This month the new Hungarian gun manufactory will deliver the first part of the Government order consisting of 40,000 rifles. A short time ago this establishment was visited by the English engineer, Mr. Greenwood, at whose recommendation several improvements will be made. The joint-stock company, formally Danek, of Prague, is issuing its annual report, which shows that its works were more busy last year than ever before. The company declared a dividend of 10 per cent. The Kronstadt Mining Company held its general meeting last week. The joint stock of this company amounts to two million florins, and the profit last year was 245,000fl.

The Coal Market.—No change worthy of notice has happened in the coal market since last report. The market continues animated, and prices are so high that the industries depending on them are very oppressed. There is an extraordinarily brisk export by the Elbe.

Metals.—The Bleiberger Bergwerks-Union, which is one of the chief lead producers in the empire, held a meeting last week. A dividend of 5 per cent was declared.—A good idea of the metal traffic is to be seen from the following table, where the numbers indicate 100 kilos.:—

Imports.

Metals.	1889. Jan.	1889. Feb.		1890. Jan.	1890. Feb.
Lead	2,524	4,170	...	10,108	5,804
Copper, rough	5,441	7,143	...	25,079	31,096
Copper, refined	928	934	...	1,144	1,906
Zinc	4,567	6,705	...	3,995	5,393
Tin	5,518	6,409	...	6,791	8,517

Exports.

Tin	238	273	...	132	446

BRUSSELS, 10th June, 1890.

Iron.—Though there are yet no indications of improvement in the iron market, manufacturers have begun to hope for better things. This hope is based chiefly on the fact that matters have not grown worse in the course of the last fortnight. That the bottom of the depression has been reached is probable, since it is now evident that the present level of prices for coal cannot be much longer maintained. The pig iron market continues weak in tone, and prices are irregular, ordinary forge being dealt in between 48s. and 52s. a ton. At the latter price the Athus Company has sold 15,000 tons for delivery in the second half of the year, a transaction which disposes of its production down to the end of September. The market for finished iron and steel is lifeless. There is a feeble demand for joists, but other classes are utterly neglected. Few of the works are now running more than four days a week. No. 2 bars are quoted 136s. at works and f.o.b. Antwerp. Angles are offered at the same price, and No. 2 plates may be bought for 144s. a ton. These prices are, however, little more than nominal, since there is practically nothing doing.

Coal.—The coal market is just now the chief point of interest in this industrial centre. The colliery owners, having succeeded in strangling the iron trade of this country, and thereby crippling their best customers, now find themselves face to face with German competition under circumstances not foreseen. The Westphalia coke syndicate has got the better of them in the markets of the Meurthe-et-Moselle, and already 50,000 tons have been disposed of to the Longwy Comptoir, and German coke is being sold to Belgian consumers at prices much below those current here. English coke, too, is making its appearance in our markets. The consequences may be estimated with precision. Belgian coke must be reduced to at least the level at which the foreign produce now stands. This means the much-needed relief asked for by the ironmasters to enable them to compete with English iron. Moreover, English coal is driving Belgian coal out of the markets of Holland, so that the downward movement cannot be long delayed. The home demand for coal is now very light. For the moment, quotations remain unaltered; but the tone of affairs is decidedly weaker.

Glass.—The situation of the market for glass has undergone but little change in the course of the last two or three

Digitized by Google

weeks. The extinguishing of several furnaces has given a slightly firmer tone to business, but the demand continues weak and irregular. The latest reports from the United States are not encouraging for the immediate future of the trade.

DÜSSELDORF, 10th June, 1890.

Iron.—The iron market is becoming more and more depressed. The prospect of cheaper coal leads buyers to defer every order to the latest possible moment, and as consumers have for the most part bought well ahead, business is almost at a standstill. In pig iron there is nothing doing; scarcely has a ton changed hands in the course of last week. As prices are in such circumstances merely nominal, it is useless to quote them. It is, however, worthy of mention that ordinary spiegel pig is freely offered at 95s. a ton, and Siegen forge at 78s. Production is being restricted to some extent, but it is far above present requirements. The imports of pig and scrap iron in the first four months of the year amounted to 145,478 tons, against 15,599 tons in the corresponding portion of 1889, an increase of 129,879 tons. As the exports fell off to the extent of 22,926 tons, the difference in favour of the present year is 152,805 tons. There is a fairly good demand for joists, but in all other classes of iron and steel the business is very slack. The wire and wire nail industry is greatly depressed.

Coal.—The coal question continues to occupy attention almost to the exclusion of everything else. Two remedies for the disproportion which now exists between the demand and the supply are under consideration, one to reduce the number of hands employed in and about the pits, the other to cease work altogether one day a month. The latter seems most in favour. Consumers generally have large stocks in hand. The Westphalian Coke Syndicate has, it is said, sold 50,000 tons of coke for export to France at the price of 19s. a ton. Considerable quantities have also been sold of late to Belgian and Spanish consumers, so that the tension has been greatly relieved and the market is firmer.

Westphalian Coal at Hamburg.—The consignments of Westphalian coal to Hamburg and its neighbourhood in the month of May amounted to 65,490 tons against 29,960 tons in the same month of last year. Relatively to April there was a falling off of nearly 3,000 tons To compete successfully with the importers of English coal, the merchants are now offering Westphalian produce at prices which involve a loss on the transaction. As coal had advanced 128 per cent. and coke 260 per cent. in the course of twelve months, there is nothing surprising in the collapse which has occurred in the market. Consumers are holding back in expectation of still better terms. The firm attitude of the English merchants keeps the market steady.

LILLE, 10th June, 1890.

Iron.—Weakness continues to be the dominant note of the iron market in this locality. Buyers hold aloof in expectation of easier terms. They are encouraged in this attitude by the prospect of cheaper fuel, and by the action of some of the merchants who are underselling the manufacturers. The latter affect to believe that business will revive after the turn of the year; but it is difficult to discover the grounds on which this opinion is based. The rates now current are 148s. a ton for bars and joists, 180s. for common plates, 200s. for boiler plates, and 200s. for mild steel plates. Concessions on these prices are easily obtained in orders of some importance.

Textile Manufactures.—The market for linen goods gradually becomes less active as the season advances. There is, however, a good average trade, so that the situation is to be regarded as satisfactory. Prices remain without change. At Roubaix the calm in the woollen goods trade is becoming serious, and occasions much anxiety. Manufacturers are sufficiently occupied in working off the March and April orders. Since the first of May, when the labour disturbances began, no fresh orders of importance have been received. The prospect is decidedly gloomy. German competition, always formidable, has gained much by recent strikes. Those disturbances have done incalculable injury to the trade of the Roubaix district.

Flax and Yarns.—The situation of the flax market has changed somewhat in the course of the last week. The prospects of the new crop not being good, consumers are disposed to buy more largely. The demand is very brisk for home-grown flax, and the market in Russian is decidedly more active. Higher prices have been paid all round. There is a moderate demand for tows. Yarns are more sought after. Business having become brisk, spinners advanced their prices. The rise seemed to stimulate rather than check the demand. Jute yarns are being freely bought at constantly advancing prices.

AMSTERDAM, 9th June, 1890.

Railways.—The State Railways Company has issued its report for 1889. This company works 1,488 kilometres of railways belonging to the State at a certain percentage of profit, and also a number of private railroads. Including these, the gross receipts reached 13,787,752 guilders last year, against 13,537, 940 in 1888, whilst the working expenses were 6,766,097 guilders (49·07 per cent.), and the total disbursements 12,076,778 guilders, against 11,898,873 guilders in 1888. The amount available for dividend was 1,374,470 guilders; of this the shareholders received 777,331 guilders on a share capital of 12,883,000 guilders, and the State got 597,139 guilders. The number of travellers was 6,181,491, against 5,866,494 in 1888.

The North Sea Canal.—The Second Chamber of the States-General has passed the Government Bill abolishing the canal dues on this important waterway.

Dutch South African Railway.—This undertaking has just made another successful issue of its four per cent. debenture loan, at Amsterdam and Berlin, the amount offered (1,878,000 guilders) at 99 per cent. being subscribed several times over. The loan is repayable in forty-three years, and is required for the construction of further sections of the road between the Portuguese frontier and Pretoria.

New Steamer.—The launch has just taken place at Feyenoord of the new screw steamer "Carpentier," built by the Royal Steamboat Company for the Royal Mail Packets Company, and intended for the subsidised mail service between Holland and Insuland. It is a vessel of 1,200 tons register, having a length of 235ft., and a breadth of 32ft. The engines and boilers have been constructed at Feyenoord also. The engine is 1,250 h.p., and will enable the vessel to keep up an average speed of thirteen knots an hour. The vessel is lit by electricity, and is fitted up most luxuriously.

COPENHAGEN, 7th June, 1890.

Paper Industry in Norway.—The rebuilding of the Drammenseloen's paper works, close to the Gjethus waterfall, which was burnt down last year, is progressing satisfactorily, the mild winter having materially assisted the builders. It is expected that the paper manufacture will recommence in August or September. The new buildings are on a larger scale than those destroyed by fire, and are remarkably well constructed. The wood pulp manufactory, which was not burnt down, produces about 10,000 tons of wood pulp annually. The new works will have two large machines of the most approved type. The new electric light installation comprises two dynamos, with four arc lamps and 375 incandescent lamps.

The Peat Industry.—The peat industry is attracting more and more attention in Scandinavia. It is not only being used for sanitary and stable purposes, &c., but it is also becoming a far more important fuel. A number of experiments have been going on in various directions, and both in Sweden and Norway such good results are said to have been attained that peat may soon be used as fuel for steamers, locomotives, &c.

The Vigsnes Copper Works.—The prospects for the continuation of these works appear to be more favourable. The Board have decided to continue the working of the pits with a reduced staff. The managing director has published a statement, in which he complains of several unfavourable circumstances attached to mining enterprises in Norway. Among others, stress is laid upon the fact that wages for such work are about 45 per cent. higher in Norway than on the Continent.

Merchant Steamers in Norway.—The merchant fleet of Norway comprises 6,697 sailing vessels, with an aggregate tonnage of 1,396,998 tons, and 536 steamers with an aggregate tonnage of 137,542 tons. The principal owners reside in Christiania, Arendal, Stavanger, Bergen, Drammen, Frederiksstad, Kragerö, Grimstad, and Tönsberg.

Seal Hunting.—The seal catching vessel "Vega," which arrived at Vardö on the 30th ult., reports that the whole fleet was fast in the ice at Jan Mayn from the end of March to the 8th of May, so that the year, so far as catching young seals was concerned, was a complete failure. The "Vega" had caught 1,300 seals.

New Telegraph Cable.—The Great Northern Telegraph Company is contemplating laying down one or two new telegraph cables between Scandinavia and England. A cable will be laid between Gothenburg, on the Swedish side of the North Sea, and Newcastle-on-Tyne on the other side. This will be the first direct cable between Sweden and England. This new cable is expected to bring about a material increase in the Swedish telegraphic intercourse, as a large number of telegrams are likely to be sent by the new line from Russia and Northern Asia to England.

MADRID, 9th June, 1890.

Tinplate Works at Bilbao.—The tinplate works of Messrs. Goitia are doing well at present; they are favoured partly by the heavy import duty, and by the quality of the steel billets made at the works of La Viscaya. They are now making 200 boxes per day, but they consider that their works should be able to produce 300 boxes with the same plant.

La Robla and Valmaseda Railway.—The Bill for this railway has now passed both Houses, and most likely the works will begin this summer, and will be proceeded with as fast as possible. The engineer has decided to have all his rolling stock made in England instead of Belgium or Germany.

Ore Exports.—The Bilbao strikes, together with the falling of prices in England, have been against the continuance of the rapid shipment of ores which has existed for the last two or three months. As the freights are rather low, the deficiency may, however, be made up in the summer months. The pig iron market is very irregular, and no one knows exactly the price at which pigs may be bought.

Phosphates.—The Caceres phosphate mines have stopped altogether, as the ores are too poor for export even after hand picking. The company established a plant to make superphosphates, but it seems that they are not doing well. Great efforts are now being made to make a railway to what is considered a rich district for phosphates in Logrossan in the south of Estremadura. In the province of Murcia, the mines of Jumilla are supposed to contain excellent apatite, but it is very doubtful whether it occurs in such quantities as to warrant the large investment that a Belgian company has made in plant to concentrate their mineral.

NEW YORK, 1st June, 1890.

The Iron and Steel Trade.—The iron market has been considerably unsettled, and some very low prices have been offered. There has been little doing in pig iron; prices are steady, and there is much less disposition to allow concessions. No. 1 foundry iron can be had in almost any quantity at $18 to $18·50 per ton, No. 2 at $17 and grey forge at $15·50 to $16. Southern irons can be had from 50c. to $1 less per ton, but consumers are not taking much of it in Eastern markets. Advices from the South however, indicate a better feeling, and a general movement towards better prices is expected in a short time. Manufactured iron has not improved, although prices are generally well maintained, and in a few instances better rates have been secured. A moderate increase in the demand would quickly result in higher prices. Several important contracts are in negotiation, and it is more than likely that the mills will have plenty of work by the end of the month.

The Coal Trade.—The anthracite trade has not altered. The trade in Philadelphia is dull, while in New York business is fairly good, and the inquiry for some sizes of coal is improving. The impression is now general that within the next two months the demand for coal will begin to increase, and that for the remainder of the year trade will be brisk.

Connecting the Americas.—Representative McCreary, of Kentucky, introduced a Bill the other day to provide for a survey to be made to encourage the construction of an inter-continental railway to connect North and South America. The Bill authorises the President to invite the several Governments of Mexico, Central and South America, to co-operate with the United States in the appointment of an international commission to examine the possible routes, costs, and advantages, and to make a survey for the railway. This commission of engineers is to meet in Washington as soon as practicable, and will be composed of not more than three engineers from each nation. The construction and operation is to be at the cost of the concessionnaires, and the expenses of the surveys, salaries of commissioners, &c., are to be borne by the nations accepting the proposition.

Heliographic Signalling.—The greatest achievement in heliographic work in this country was accomplished during practice in the department of Arizona last week. Lieutenant Witteweyer succeeded in signalling a message by a single flash 125 miles, from Mount Reno, near Fort McDowell, to Mount Graham, near Fort Grant, where it was received by Captain Murray. The latter, by turning his instrument, flashed the message to Fort Huachuaca, a distance of 90 miles, making a distance of 215 miles with a single intervening station. The longest distance heretofore made with a single flash is said to be about 75 miles.

A Large Packing Plant.—A party of capitalists, on which Mr. P. D. Armour, of Chicago, is the head, have obtained nearly 2,000 acres of land at Hunter's Point, of the southern extremity of San Francisco, on which they will establish a large pork packing and beef canning plant. The capital of the new enterprise is $2,000,000. A number of Sioux City capitalists recently secured a large tract of land on the opposite side of the bay for the establishment of a packing house of the same kind.

PHILADELPHIA, 30th May, 1890.

Labour Troubles.—The strike at the National Tube Works at McKeesport has ended by the men going back to work. They demanded an increase of wages, but the company offered a satisfactory compromise. Several thousand men were involved in the strike, as the National Rolling Mill was also shut down. The miners employed at Scott's works and along the Youghiogheny River have been out on a strike for the Columbus scale. The firm offered 1c. less than the scale, which was accepted by the men.

Rapid Transit.—The problem of rapid transit in our cities has usually been approached in a haphazard manner. generally no well-digested plan being formed beforehand, To provide such a plan for Philadelphia a Rapid Transit Commission has been created. The Commission is directed to consider the various methods of rapid transit which have been suggested, and to evolve from them a system which will meet the demands of every section of the city. The work must be completed by October, and the scheme determined upon is then to be reported to the city councils. The Commission consists of the Mayor, Presidents of both branches of Council, chairmen of the committees on railroads, finance, highways, city property and surveys, presidents of the Pennsylvania, Philadelphia, and Reading, and of the Belt Line Railroads, of the principal street railway companies, and numerous prominent citizens. Committees were appointed to obtain information, and it is hoped that the labours of the Commission will result in a practical solution of the problem.

IMPROVEMENT OF THE LIVERPOOL SOUTH DOCKS.

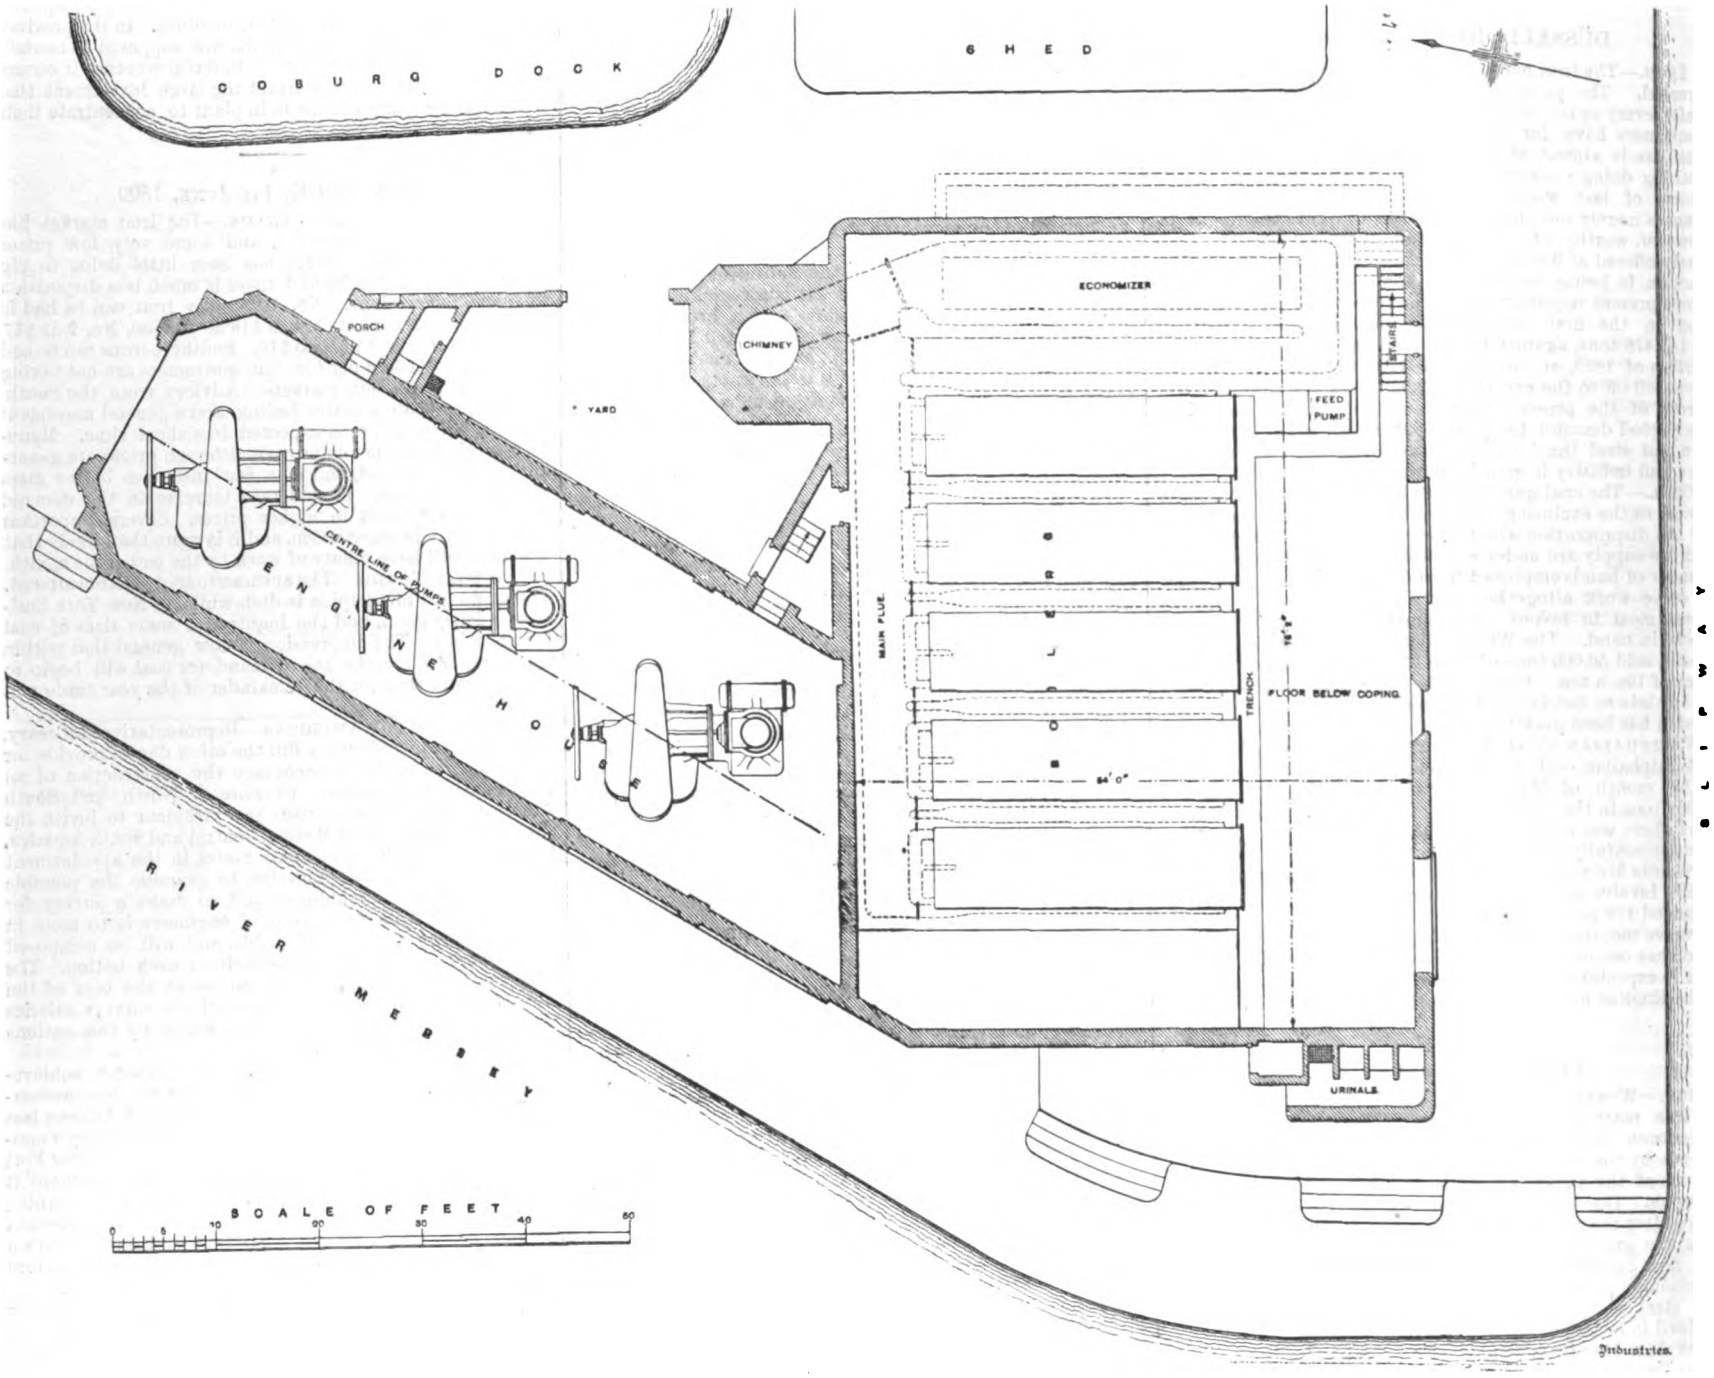

FIG. 1.—PLAN OF BUILDINGS AND PUMPING PLANT AT ENTRANCE OF COBURG DOCK.

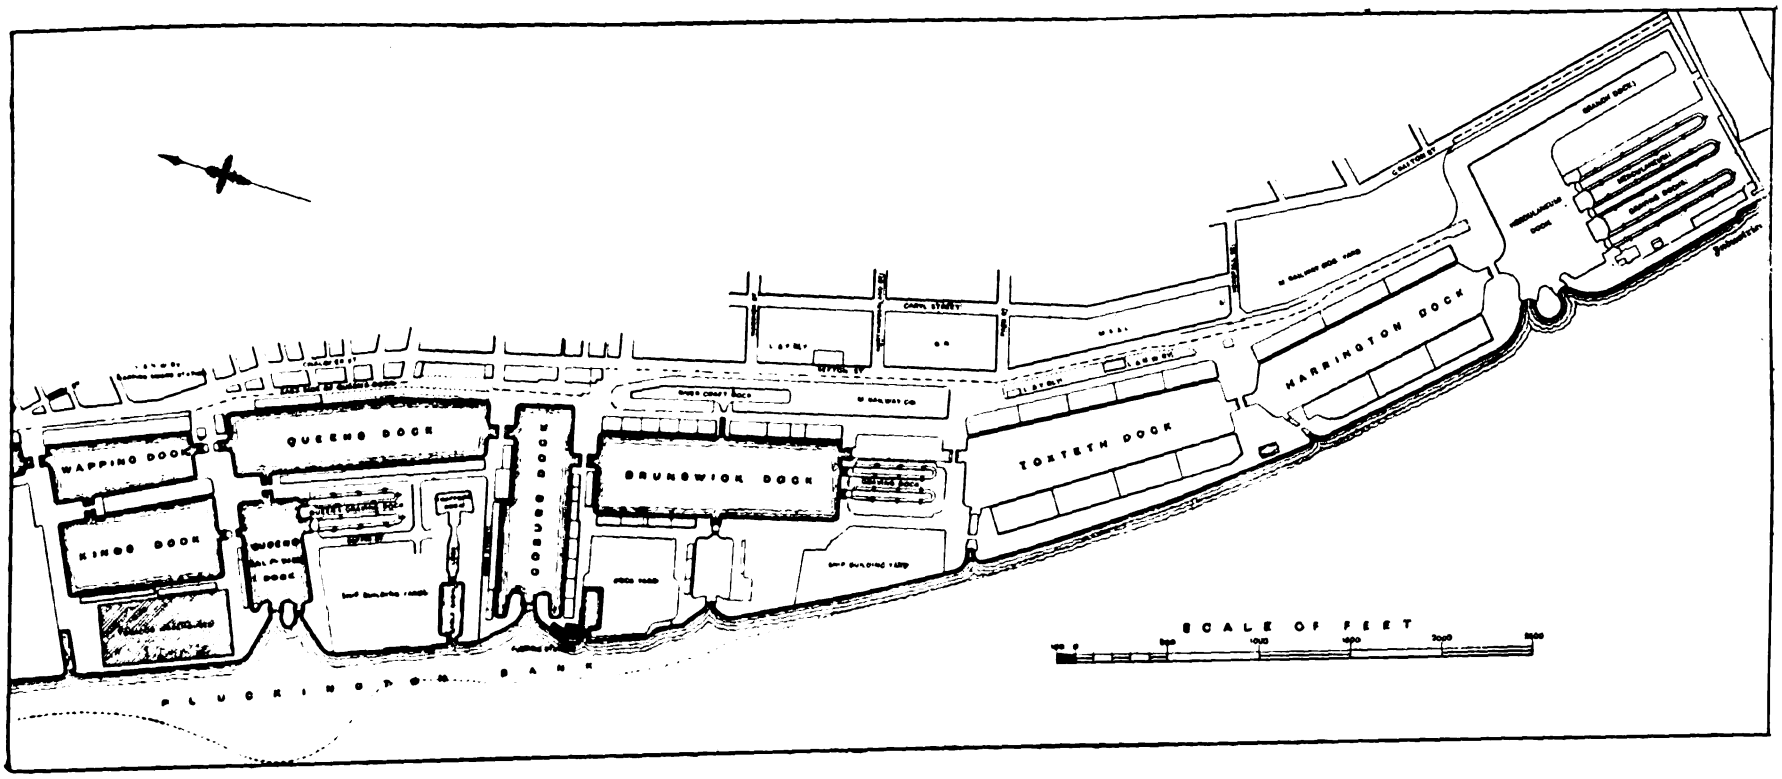
IMPROVEMENT OF THE LIVERPOOL SOUTH DOCKS.



WE are enabled to lay before our readers, through the courtesy of Mr. George Fosbery Lyster, M.Inst.C.E., Engineer-in-Chief to the Mersey Dock Estate, an illustrated description of an important scheme for the improvement of a number of the docks at the south end of the Liverpool dock system, which has been in successful operation for several months. Although these docks were constructed for the accommodation of the largest steamers and sailing vessels afloat at the time of their construction, within the last few years the steamers have attained such enormous proportions, both as regard tonnage and draught, that the depth of the sills quite prevent them from entering the docks in question, except during favourable tides near high-water time. As these favourable conditions only occur at high spring tides, it was necessary, to make the docks available for all classes of shipping at all tides, to either rebuild the entrances and increase the depth of the sills and the dock bottom generally, or to provide some other means of gaining access to the docks. As the tail of the Pluckington Bank unfortunately lies across the entrance to many of the south docks, it was considered useless to construct entrances with deep sills, seeing that they could not possibly be approached. Even if they could, the cost of deepening the docks and underpinning the walls would be very great. Mr. Lyster, therefore, conceived the idea of impounding the waters in the various docks and using powerful pumping machinery to assist as far as might be necessary in maintaining the abnormal level by making good the losses due to locking, leakage, filling graving docks, sluicing, &c. Large vessels could then enter the newer or southernmost docks which have deep sills at a part of the river not obstructed by the Pluckington Bank, and thence be locked into the older docks with the shallow sills. This pumping system had already been tried on a smaller scale with the Sandon Dock, in order to give access to an important series of graving docks there; and as it had been so very successful it was decided to adopt it on a more extensive scale at the south docks.

By referring to Fig. 2, page 561, which shows a portion of the south dock system, it will be seen that the Wapping, King's, Queen's, Coburg, and Brunswick Docks are connected together, and, by the Union Dock—serving as a lock—to the Toxteth, Harrington, and Herculaneum Docks. The sills, however, of the first five docks do not in any case exceed a greater depth below datum than 6ft., while those of the three latter, including the entrance to the river at the Herculaneum Dock, are 12ft. below datum. The average high-water mark of ordinary spring tides, excluding the equinoctial tides, is 18ft. 10in. above datum, the average high-water level of neap tides being 11ft. 7in. above datum; it will be seen, therefore, that a vessel drawing 23ft. or 24ft. of water could enter the Toxteth, Harrington, and Herculaneum Docks during any tide of the year, while with ordinary conditions it could only enter the other five docks during high spring tides. By pumping the water into these five docks to an increased depth of 6ft., an effective depth of sill corresponding to that of the other docks can be given. Large vessels, therefore, wishing to enter the shallow sill docks, enter the Herculaneum Dock, pass through the Harrington and Toxteth Docks, and are then locked through the Union Dock into the Brunswick-Wapping dock system.

When this system of pumping was decided upon, Messrs. J. & H. Gwynne, engineers, of Hammersmith, were consulted, and it was left to them to design the necessary machinery for pumping the specified volume within a given time—that is, for raising an area of about 50 acres to a depth of 6ft. The machinery and arrangement of it are so clearly shown in the several illustrations that no description is necessary beyond giving a few of the leading particulars. Fig. 1 above shows the plan of the machinery, boilers, buildings, &c., as fixed at the entrance to the Coburg Dock, and indicated on Fig. 2. The pumps are of the well known "Invincible" type made by Messrs. Gwynne, and are shown in detail in Figs. 3 and 4, page 564. The disc or fan of each of the river pumps is 90in. in diameter, the pump casing being 16ft. 6in. diameter; the suction and delivery pipes are 54in. diameter, and have bell-mouth ends, as shown in the illustrations. Each pump is driven direct by a compound vertical engine with cylinders 40in. and 22in. diameter respectively, with a stroke of 30in., and running

Digitized by Google

PLAN OF THE LIVERPOOL SOUTH DOCKS.

90 revolutions per minute. The whole of this plant was constructed by Messrs. J. & H. Gwynne, at the Hammersmith Ironworks. Steam is supplied from five steel boilers of the Lancashire type, 30ft. long, 7ft. 6in. in diameter, each of the flues being fitted with four Galloway tubes, the working pressure being 100lb. per square inch. The boilers were made by Messrs. Joseph Foster & Sons, Preston. The feed water is passed through a Green's economiser having five groups of 64 pipes in each—360 pipes in all. The boilers are fitted and mounted according to the most modern practice, and to the full requirements of the steam boiler insurance companies. The machinery has now been in operation for some months with most satisfactory results, and at the first official trial, when approximate gaugings were taken, it was found that the quantity of water delivered by the pumps was greatly in excess of the specified quantities.

A similar system of raising the dock water level, so as to make the shallow sill available for vessels of deep draught, has just been completed by Mr. Lyster in the Birkenhead Docks. The machinery in this case was also designed and supplied by Messrs. J. & H. Gwynne, and at the recent trials the results were eminently satisfactory. These pumps will enable deep-draughted vessels to use a dock system of 130 acres on a tide, when they can pass over a 12ft. sill.

Trials of the engines, boilers, and pumps, of both the Liverpool and Birkenhead stations, are shortly to be made, when we hope to lay the detailed results before our readers.

PRICES CURRENT, 11TH JUNE, 1890.

Quotations at per ton, unless otherwise specified.

METALS.

Tin:	Straits	96	17	6	,,	97	5	0
,,	Australian							
,,	English Ingots	101	0	0	,,	.....		

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER has been very excited during the past week, and values of raw have advanced about £4 a ton, a large business having been done at prices ranging from £54 10s. to £58 15s. for cash. There has been an increased speculative inquiry on American account, principally in three months' metal, the demand for consumption there being very active for electric purposes, &c. There has also been a very large demand for sulphate of copper in France for the vineyards. The Customs' returns just issued are of interest, showing that the imports for this year are far less, and the exports considerably greater, than for the same period last year, viz.:—

	From Jan. 1 to May 31.			May only.	
	1890.	1889.		1890.	1889.
Imports, total tons	53,908	62,482	...	11,041	13,090
Exports, ,,	36,513	16,218	...	7,968	5,885

These returns have helped to strengthen the market. A somewhat easier feeling is observable to-day in Chili bars, quotations being £57 10s. to £57 17s. 6d. cash, with good business. Manufactured has been advanced to £70 sheets, £73 bottoms, and a fair business has taken place recently.

TIN has been strong all the week, and prices have advanced considerably. The decrease of about 580 tons in stock during May, and the light shipments from the Straits, have induced large buying, at advancing rates.

LEAD steady, and without change in price. An improved demand is reported, and values are likely to be firmer.

SPELTER very firm and advancing, the stocks being everywhere small, and makers sold forward for some months.

ANGLES, PLATES, BARS.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

CHEMICALS: A moderate business has been passing in alkalies, but prices of caustic soda and bleaching powder are a little lower. Bicarbonate of soda is also easier. Soda ash is steady, and soda crystals are in demand. Chlorate of potash very quiet. The inquiry for carbolic acids is slacker. Benzoles are unchanged. Fair business doing in sulphate of ammonia. Oxalic acid is active, and tartaric and citric acids are firm.

HOME INDUSTRIES.

LONDON, 12th June, 1890.

The Money Market.—Money has been much scarcer this week, as the payments on account of an issue of Treasury bills have cleared the market of its surplus supplies. The considerable demand arising out of the Stock Exchange settlement has also tended to make money dearer, and as much as 2¼ per cent. has been charged for accommodation for short periods. The discount market has moved more in the direction of ease, the Paris cheque rate having risen in our favour and considerable sums in gold having come into the Bank. The stock markets have been rather depressed this week, and the settlement has occupied most attention. Prices gave way just before the close of the account, as many speculators for the rise desired to realise their profits. Home railways have been quiet, with the exception of Caledonians, which have been strong on the passage of the Bill for splitting the stocks. The other stocks affected by conversion Bills are less active, and therefore attention was concentrated on Caledonians. The mineral lines have been rather neglected, and the southern railway stocks have been out of favour. American railroads have been steady, without any distinguishing feature. Mexican Central securities have been very prominent at considerably higher prices, but the stocks of the Mexican Railway (Vera Cruz) have fallen greatly, the traffic returns being consistently unfavourable. Foreign stocks, after a long period of firmness, gave way on Tuesday, Paris withdrawing the support given to them from that quarter for some weeks. The close of a campaign against the "bears" of copper shares was witnessed this week. Gold mining shares have been neglected, and there has been no feature of importance in industrial and miscellaneous securities

Companies.—The following companies have been registered since our last report:—Sumatra Exploration Co., Ld., with a capital of £250,000; The Vulcan Patent Smoke Consumer and Fuel Economiser Corporation, Ld., with a capital of £70,000, to carry on the business of engineers, &c.; Steam Cylinder Lubricator Co., Ld., with a capital of £10,000; Patent Multiple Engraving Machine Syndicate, Ld., with a capital of £6,000; Briton Ferry Patent Carbon Fuel Co., Ld., with a capital of £10,000, to carry on business as patent fuel manufacturers, iron founders; The Glenrock Co., Ld., with a capital of £225,000, to carry on mining operations, &c., in New Zealand; The Penrikyber Navigation Colliery Co., Ld., with a capital of £350,000; St. George (Queensland) Gold Mining Co., Ld., with a capital of £55,000; Blackpool Brick Manufacturing Co., Ld., with a capital of £2,000; The San Jacinto Estate, Ld., with a capital of £505,000, to purchase mines and mining property in California; Drachenfels Banket Gold Mining Syndicate, Ld., with a capital of £25,000; Suyapa Silver Concession, Ld., with a capital of £10,000; Ratcliff & Horner, Ld., with a capital of £20,000, to carry on business as mechanical engineers; Bishop's Stortford Electric Light and Steam Laundry Co., Ld., with a capital of £10,000; Puiel Estate and Exploration Co., Ld., with a capital of £40,000; Hull and Liverpool Red Oxide Co., Ld., with a capital of £75,000.

The Board of Trade Returns.—The total value of the exports for the month of May amounted to £22,940,779, as compared with £20,421,394, in May last year, being an increase of £2,519,385, or 12½ per cent. In May last year the exports showed an increase of 5½ per cent., so that there has been a very decided improvement on the two years. It must also be taken into consideration that the Whitsuntide holidays interfered with trade in the last week of the past month, which makes matters still more satisfactory. The exports of yarns and textile fabrics were £9,344,807, as compared with £8,622,509 in the same month of last year; the exports of metals and articles manufactured therefrom, except machinery, were £4,278,321, as compared with £3,620,679; machinery and mill work amounted to £1,601,857, as against £1,295,046; and chemicals and chemical preparations, £828,279, as against £697,892. The imports again show a decrease, being £33,341,005, as against £34,835,408 in May of last year. Metals amount in value to £1,888,375, as compared with £1,694,075; chemicals and dyestuffs to £649,493, as compared with £810,562; oils to £460,957, as compared with £438,509; raw materials for textile manufactures to £5,907,126, as compared with £7,776,424. The total value of the exports for the five months ending 31st May were £106,023,148, as compared with £100,712,988 for the five corresponding months of last year. The imports for the five months of this year were £174,084,463, as compared with £178,661,794.

The Royal Agricultural Show.—The fifty-first annual Exhibition of the Royal Agricultural Society of England will be opened at Plymouth on the 21st inst., and close on the 27th inst. The machinery in motion shedding will be 1,291ft. in length, as compared with 2,496ft. last year; the ordinary shedding 6,117ft., as compared with 10,378ft.; and the special shedding (including seeds, models, &c.) 1,670ft., as compared with 2,728ft. The total entries of live stock also show a decrease.

Society of Engineers.—Arrangements have been made for the members and associates of the Society and their friends to visit the Thames Ironworks, Blackwall, and inspect the ironclads in course of construction, on Tuesday, the 17th inst. The party will travel by the London and Blackwall Railway to and from Blackwall. The following is the time table:—2.10 p.m., leave Fenchurch Street Station; 2.35 p.m., arrive at Blackwall Station; 2.45 p.m., inspect works; 5.0 p.m., leave works; 5.20 leave Blackwall Station; 5.35 p.m., arrive Fenchurch Street Station.

The American Meetings of the Iron and Steel Institute.—The programme for the visit of the members of the Iron and Steel Institute to the United States has recently been issued. There will be three different sets of meetings—the first, the meetings of the American Institute of Mining Engineers (the most prominent technical body in the United States), which take place in New York on the 29th and 30th of September; the meetings of the Iron and Steel Institute, which take place in the same city on the 1st, 2nd, and 3rd of October; and the international meeting promoted jointly by those two Societies, which will take place about the middle of October at Pittsburg. The excursions which have been planned by the American reception committee, of which Mr. Andrew Carnegie is chairman, provide for about 3,000 miles of free transportation through the United States. The principal excursions will take place to the iron ore and copper regions of Lake Superior, to Philadelphia, Harrisburg, and Chicago, where there are large iron and steel engineering works to be inspected, and to the new iron-making district of Alabama, which has lately come very prominently to the front, and in which English capital has become very largely interested. About 300 members of the Iron and Steel Institute and 100 German ironmasters have intimated their intention of taking part in the meetings, and already many have booked passages in the Hamburg-American Packet Company's "Normannia," leaving Southampton on the 12th of September. The meetings and excursions will last over a month, and will practically embrace every point of interest in the United States within a distance of 1,500 miles of New York. A number of important papers have been promised for the meetings by such well-known scientists as Sir Lowthian Bell, Sir Nathaniel Barnaby (the late chief constructor to the Navy), and Sir Henry Roscoe. Amongst others who have intimated their intention of being present at the meetings are Sir James Kitson (president of the Institute), Lord Edward Cavendish, Sir John Alleyne, Sir James Bain, Mr. Hingley, M.P. (president of the Iron Trade Association), Mr. Theodore Fry, M.P., Sir J. J. Jenkins, Sir Thomas Story, Mr. A. Windsor Richards, Mr. Snelus, F.R.S., and Mr. Ed. Pellartin.

The Electric Lighting of New Scotland Yard.—The new central offices of the Metropolitan Police on the Embankment are being fitted throughout with the electric light. Altogether some 1,260 incandescent lamps will be employed to light the 300 rooms and corridors. The wiring is arranged with alternate lamps on different circuits supplied by separate engines and dynamos. It has been determined to put down a special generating plant. The plant will consist of three Lancashire boilers and four sets of engines and dynamos having a combined capacity of some 160 electrical horse-power. They will be placed in an underground engine-house excavated outside the main building. There will also be a battery of accumulators capable of maintaining 200 lights for nine hours when the engines are at rest. The installation, which will be one of the largest and most complete of the kind in London, is being carried out to the specification of Mr. A. A. Campbell Swinton.

Electric Lighting.—Following the example of all the new theatres in London, the latest addition to the music-halls of the metropolis—viz., the Tivoli—has been lighted electrically. The arrangement of glow lamps is effective, and the fittings neatly designed. The hall, which is in the Strand, nearly opposite the Adelphi Theatre, is supplied with current from Messrs. Gatti's installation. The whole of the fittings have been carried out by Messrs. Rashleigh, Phipps, and Dawson.

Churchill's Marine Governors.—Messrs. Durham, Churchill, & Co. have received an order for two marine engine governors for the "Polar Star," the new yacht for His Imperial Majesty the Czar; also two governors and compound attachments for the new Russian ironclad "Azof," of 11,500 i.h.p.

Jeyes' Disinfectant Fluid.—We are informed that Jeyes' Sanitary Compounds Company has obtained an order to supply their disinfecting fluid to Chinese passenger ships.

MANCHESTER, 12th June, 1890.

Railway Rates.—In a letter addressed to various trade associations in Lancashire, the representatives of the spinners before the recent Commission have reported the result of their efforts. The charges as proposed by the railway companies raised the cost of carriage of 578,174 tons of cotton—which is the amount brought into the district in a year—from £240,000 to £440,000. The representatives recommended the following rates for pressed cotton bales. For each mile, 2d. per ton, with a terminal charge of 2s. where services are rendered by the companies. This is equal to a charge of 3·20d. per ton per mile when the distance carried is twenty miles. These charges would considerably increase the revenue of the companies.

The Linen and Jute Trades.—In nearly all of the warehouses quietness prevails in the heavy departments. Tuesday was a fair day for the fancy branches, and considering that no one expects to do much at this time of the year in coarse goods, linen sales were not unsatisfactory. Retailers are stocked for a little ahead, and the wholesale houses are giving out very few orders just now. German manufacturers have been pushing their fancy goods for the Christmas trade, even at this date. They will take a three months' bill in payment, and seem fond of booking as far in advance as possible. Their goods being specialties, in which competition on the part of British or Irish firms is practically *nil*, buyers have been found willing to accommodate them in this way. Home manufacturers are not so fortunate, the tendency being to put as many strains upon them as possible, by purchasing in a hand-to-mouth fashion. The most notable feature of the linen trade at the present time is the rush on the part of shippers to stock the New York market as much as possible before the new tariff legislation can have effect. The activity prevailing from this cause alone is exceptional and of a character rarely seen. The United States is far and away the leading market for linen, and the probability that it will shortly be partially closed amongst European exports is a serious matter for producers. There is no change in linen threads, and jute goods are in the same condition as linens.

Wages in the Cotton Trade.—A conference of representatives of the employers and employed in the weaving industries was held on the 10th inst., to endeavour to come to some understanding with reference to the proposed standard wages list. It is stated that an agreement is likely to be come to, and the threatened great strike of operatives is for the present postponed.

Rope Driving.—We have recently inspected a system of rope driving which is devised to overcome some of the difficulties of the ordinary method. Instead of using a number of separate ropes a single rope is used, which is spirally passed round the pulleys as often as possible. The slack is taken up by a compensating arrangement applied to the last coil, and all the remaining coils are kept tight, both back and front, there being none of the bagging of the slack side usually noticed. The effect of this arrangement is to ensure a uniform diameter throughout the life of the rope, and so prevent the unequal engagement of it in different grooves which is observable in the ordinary system. The drag set up by ropes being unequally geared is entirely obviated, and a perceptible improvement in the steadiness of the ropes is noticed. This system is also applied to self-acting mules with success, and it is claimed that much of the loss of power usually existing is prevented.

GLASGOW, 12th June, 1890.

Pig Iron.—A rather remarkable change has come over the pig iron market here within the last few days. While the accounts published in all the papers are of the most doleful character, all pointing to the necessity of lower prices before fresh business can be expected to come on, speculative purchases on a large scale have been made at rapidly advancing prices. Warrants for Scotch, hematite, and Cleveland iron are almost entirely out of the hands of dealers, and seem to have been absorbed by a numerous class of investors, whose principal reason for buying and holding is that iron cannot be made at present prices, and that the cost price cannot be appreciably reduced. The "bears," on the other hand, have rather overshot the mark, and have possibly made out things worse than they are; they get uneasy whenever a little rise shows that the downward course is not a certainty; so that there was a great deal of anxious buying when Scotch warrants had been carried up to about 44s. 9d. and 45s.

Shipbuilding.—At Renfrew Messrs. Wm. Simons & Co. are busy with a large number of dredgers. They are building a large one for the Manchester Ship Canal Company, which will be launched in a few weeks, one for the Nicaragua Canal, two for Santos, two for Durban, and one for Spain. They have also sold a dredger of their well-known type to the Japanese Government, for service at Yokohama. This dredger is ready for despatch. The same firm are fitting upon one of their dredgers a sand pump plant for the Mersey Harbour Board. The pump is one of Messrs. Simons' patent centrifugal pumps, and is capable of throwing about 400 tons of sand per hour. It is intended to be employed upon the bar of the River Mersey.—Messrs. Russell & Co., Port Glasgow, are building two steel vessels for Messrs. Thomson, Dickie, & Co., Glasgow. The vessels, which will be named the "Culmore" and "Templemore," are to have a registered tonnage of 1,685 tons, and carry over 2,800 tons each. They were contracted for some time ago at £19,750 each.—Messrs. Fleming & Ferguson, shipbuilders and engineers, Paisley, have received an order from Mr. Christen Thorbjornsen, of Christiania, to supply a set of their patent improved quadruple-expansion engines, to indicate 500 h.p., for his s.s. "Erling," these engines being substituted for the compound now in the "Erling." This will be the twenty-sixth set of this type of engines constructed by Messrs. Fleming & Ferguson.

A New Method of Printing on Handkerchiefs for Embroidery.—A new method of printing designs on handkerchiefs for embroidery work has just been patented by Mr. Hugh A. McColl, designer, Glasgow. The process is exceedingly simple, and consists of a roller whose circumference is exactly ¼in. larger (forming the baulk) than the size of the handkerchief to be printed. The lines of the design are drawn upon paper in the usual way and in the required colours, and are then transferred to the roller. The handkerchief, or web of handkerchiefs, is then passed under the roller, when the various colours of the design are printed on it in clear and clean lines. It will thus be seen that any number of colours may be printed at once and from a single roller—an obvious advance on the old method of perforating or block-cutting the design and

Digitized by Google

then stencilling it on to the handkerchief. This is one of the advantages claimed for the process, besides the rapidity with which the designs are printed. Several of the largest manufacturers in the trade have already seen it at work, and consider it a great advance in the right direction. It will be at once seen that the amount of colour absorbed by the roller must in time become expended when it is necessary to replenish it. This would mean considerable expenditure of time, but, we believe, Mr. McColl has under consideration a method for obviating this difficulty, by which, without any appreciable loss of time, the roller is again filled with colour and ready for work. Or, if more than one roller was in use, the printing could go on almost without interruption as, when one roller got used up, another could be substituted, and so on. The composition of the roller is such that, if laid aside unused for some time, the colours sink, and a new design can be placed over the old one without in any way letting the two designs become mixed.

(From our own Correspondents.)

LIVERPOOL, 11th June, 1890.

The Furniture Wood Trade.—There has been a distinct improvement in the tone of the market during the past month, and for some classes of timber there was an advance in the prices realised at the sales. The stock of Honduras mahogany is very light, and there have been no recent sales. The stock consists of a portion of two cargoes. The stock of Tabasco is light, and is in active demand, a cargo of Laguna wood realising advanced prices at a recent sale. Minatitlan is in active demand, and prices are well maintained. There is a good opening for Tlacotalpam and Tecolutla, the market being bare. Logs of St. Domingo mahogany are in request, and good prices are realised. Curls of good quality are in demand, and meet with ready sales, but for second quality there is no demand. There is only one cargo of Cuba mahogany in stock to meet the steady demand; of African the market is bare, and there have been no recent sales. The demand for Honduras and Mexican cedar has improved, and fair prices are obtained for sound wood. The consumption of pencil cedar is limited, and the stock is light. There is a good demand for American walnut, and as the import has been small the prices have improved. The demand for Italian and Circassian is, however, very limited. The large arrivals of white wood have made the prices easier, dealers not caring to have too large a stock at this time of the year. The high price of rosewood has restricted the sale. Satinwood is in request, prices being high and the market bare. Lignum vitæ is in demand at fair prices, and the stock is reduced to a few tons.

SHEFFIELD, 11th June, 1890.

Iron and Steel.—There is a good demand for merchant iron of all classes, and local houses are fully employed, mainly in the production of best brands. Pig iron of all grades has fluctuated considerably in value lately. Rolling mills are well employed. Armour plate mills are fully employed on work for the British Government, which will last some time yet. A great change is quietly coming over the file trade owing to the introduction of machinery, which has now reached great perfection. Files are now forged, ground, cut, and finished by machinery, and are undoubtedly superior to any goods produced by hand. Germany is much the best customer, and is, in some cases, the only one to take advantage of these improved methods.

Coal and Coke.—A very quiet tone prevails throughout this district. There is no doubt that the demand for coal of all kinds has fallen off considerably during the last month, and merchants find it difficult, if not impossible, to maintain last month's rates. Railway companies, who buy largely in this district, find themselves called upon to pay from 2s. to 3s. per ton more for coal than when last year's contracts were made. Gas companies have had to pay a much higher price than usual for their supplies; but owing to improved methods of coke-making, and the high market value of that commodity, they have been able to make handsome profits.

NORTH STAFFORDSHIRE, 11th June, 1890.

The Iron Trade.—The opinion is gaining ground that the autumn will bring with it a substantial improvement in the state of the iron trade. Consumers are holding back orders, which will then no doubt have to be placed. In the meantime, there is little if any profit for producers, and mills and forges are working short time. Ironworkers have agreed to a reduction of 3d. per ton for puddling until the next ascertainment of prices under the sliding scale. Pig iron shows further weakness in the matter of price.

The Coal Trade.—At this time of the year some heavy contracts for local consumption in the pottery trade are entered into for the next twelve months. Though prices obtained show a considerable increase on last year's figures, they are not proportionately higher taking into account the enhanced cost of production.

LEICESTER, 11th June, 1890.

Wool Spinning and Yarn Trades.—Business in the local wool market goes very slowly, and buyers hesitate to go beyond their pressing wants. Prices are fairly firm, but holders of stocks do not press sales at current rates, as they feel somewhat uncertain as to the prices likely to rule when the new clip is on the market. Spinners, considering the time of the year, are fairly well off for business. They might do more were they disposed to accept the new business tendered, but the quotations, considering the prices for raw material, are very unsatisfactory.

Hosiery Trade.—There is a slight improvement nearly all round, but trade is certainly not above the average at this period. Some of the branches of the fancy trade are much affected by the prevalent taste for furs, which are now offered at such low prices. Trade is better in the heavy plain woollen department, and some good shipping orders are on hand.

SWANSEA, 11th June, 1890.

The Electric Light at Llanelly.—Notwithstanding the opposition of the gas company the local board have granted permission to the Llanelly Electric Light and Power Company, Limited, to apply to the Board of Trade for a licence to supply certain districts of the town with electricity. Mr. J. C. Howell is the moving spirit of the company, which has a capital of £15,000.

The Barry Dock.—The recent rumours regarding a dispute with the executors of the contractor, the late Mr. T. A. Walker, have culminated in a claim for extras, caused by the necessity for providing for a much larger traffic than the company originally contemplated, which, including the balance of retention fund, amounts to £204,454 14s. 5d. Should the directors and the executors be unable to come to an agreement, Mr. T. Wolfe Barry will act as arbitrator between the parties in accordance with the contract.

CARDIFF, 11th June, 1890.

Iron and Steel.—There is a slightly better tone in the pig iron trade, which may possibly be the natural outcome of the general belief that the lowest figures possible have been reached, considering the position of the labour and fuel market. Hematite iron is quoted at 53s. to 54s. Steel rails are quiet, and for bars there is no change in the position. In the iron ore trade arrivals have been numerous, and, as freights are low, merchants are taking the opportunity of bringing over as much ore as possible. Prices in Spain keep very firm, Rubio ore being quoted at 14s. 6d. c.i.f. Cardiff and Newport, 15s. 6d. Tees, and 15s. 9d. Glasgow. Freights from Bilbao to Cardiff and Newport are 5s. 3d.

Coal and Coke.—The steam coal market is active, and another week of large shipments has to be chronicled. Prices have exhibited no fluctuation of moment, and can be indicated at—for first quality, 14s. 6d. to 15s. 3d.; second, 13s. 6d. to 14s.; third, 12s. 9d. to 13s. 3d. The demand for small steam coal continues strong, and the high price has been sustained longer than most people expected. Quotations are 9s. 3d. to 9s. 9d. f.o.b. Cardiff, according to quality. Business in coke is quiet, and no new contracts are reported. The capital required for the Penrikyber Colliery, £350,000, has been fully applied for. It is noteworthy that the shares in Messrs. D. Davis & Sons, Limited, which was floated about a month ago, are now quoted at £2¾ to £3¼ for the £2 paid shares.

BARROW-IN-FURNESS, 11th June, 1890.

Hematite Iron.—The trade in hematite pig iron is quieter, and the prospects all round are not of a cheerful character. The output of the works has been restricted to a considerable extent, and additional furnaces will be blown out within a few days. Prices are easier, at 50s. 6d. per ton for hematite warrants and 51s. to 55s. per ton for parcels of mixed Bessemer numbers net f.o.b. There is no reason to expect any improvement in consumption until a larger demand is experienced for pig iron from steel makers generally.

Steel.—There is less life in the steel trade this week. Rails are quiet, and the inquiry shows no life on home or on foreign account. Heavy sections are quoted at £4 10s. to £5 per ton, light sections at £6, and colliery sections at £7 per ton. Steel shipbuilding material is quiet, but prices are quoted firm, at £7 for plates and £6 10s. for angles. Billets and slabs are quiet at £5, and blooms have a slow sale at £4 17s. 6d. Tinplate bars are quiet at £5 10s. delivered at works.

Hematite Stocks.—The stocks of hematite held in the district have again been further reduced, and stand this week at 302,779 tons, being 5,632 tons less than in the previous week, and 77,865 tons less than in the first week of the year. It is felt that no permanent improvement can be looked for in the iron trade until these stocks have been largely disposed of, and makers, with this view, are not in any instance making for stocks.

MIDDLESBROUGH, 11th June, 1890.

Pig Iron.—Quite a change for the better has come over the pig iron market during the last day or two. No. 3 Cleveland G.M.B., which had been declining since last Wednesday, has suddenly gone up 1s. to 1s. 6d., so that now it cannot be had under 41s. 6d., some makers asking as much as 42s. The favourable returns and increasing shipments were bound to make an impression. Altogether, the prospect is much more hopeful than it was. Connal's stores have been freely drawn upon during the week, for the stock, which stood a week ago at 102,952 tons, now stands at 100,237 tons, being a decrease of 2,715 tons. Cleveland warrants are also advancing in price being quoted at 41s. cash. In hematite East Coast brands are quoted at 57s. per ton, and West Coast, 50s. 11d. for mixed numbers makers' iron f.o.b.

Manufactured Iron and Steel.—Iron and steel are rather more cheerful in tone this week, although prices are not affected by it yet. Iron ship plates are at £5 7s. 6d.; angles, £5 5s.; bars, £5 12s. 6d. per ton; steel ship plates, £6 10s.; angles, £6 7s. 6d.; rails (heavy sections), £4 17s. 6d. per ton, all less 2½ per cent. on trucks at manufacturers' works.

Shipments of Pig Iron.—The shipments have improved considerably. Up to the 9th of the current month inclusive they amounted to 22,728 tons, against 17,392 tons to similar date in May, and 20,440 tons to similar date in June last year. Germany and Holland and other foreign countries are taking more than they have done hitherto. The shipments coastwise have rather fallen off.

NEWCASTLE, 11th June, 1890.

The Iron Trade.—A firmer tone is beginning to be manifested in the pig iron trade, shipments having somewhat increased, and the supplies in the hands of local consumers having become, in many instances, well nigh exhausted. Prices, however, are still stationary, though the feeling is pretty general that an advance may soon take place. Finished iron manufactories continue to be fairly well employed, but the works would generally be busier were customers a little less anxious to postpone the delivery of material contracted for at the end of last year. Manufacturers of ship and engine forgings are now short of orders, and work is eagerly sought for at considerably lower prices than were prevalent a few weeks ago. Business in the iron foundries still keeps brisk, but the proprietors of bolt and rivet works have found it necessary to largely diminish their production.

The Coal Trade.—Since the end of May no change of consequence has occurred in the condition of the coal trade, but it is noteworthy that miners have ceased to press for advances of wages, and the fact appears to have been brought home to them that a time of declining trade is not favourable for the successful prosecution of such claims. The shipment of coal and coke at Tyne during the week ending June 7th amounted to 111,647 tons, being an increase of 3,695 tons as compared with the corresponding week of last year.

Engineering.—The works of Messrs. H. Watson & Sons, High Bridge, are just now exceedingly busy, the demand for their steam pumps and other specialties having largely increased. Messrs. Allen & Robson, the Newcastle agents of Messrs. A & J. Stewart & Co., Clydesdale, have recently obtained for their principals a large order for steel tubes, to be used in connection with the further development of the salt mining industry in Cleveland. Messrs. Abbot & Co., Gateshead, will deliver, in the course of a few days, the last of the phosphor-bronze castings—sixteen in all—that were ordered from them by Messrs. Armstrong, Mitchell, & Co., for two large cruisers now building at Elswick. These castings, some of which weighed as much as 11 tons, were all put through a careful test, and several were found capable of standing a tensile stress of 20 tons per square inch, besides showing satisfactory elongation, and going successfully through the ordinary bending tests.

BELFAST, 11th June, 1890.

Shipbuilding and Engineering.—Both these trades continue fairly busy, and there are no empty stocks in any of the yards. Messrs. MacIlwaine & McColl have received an order from Mr. Samuel Lowther, of Belfast, for two screw steamers, each to have a carrying capacity of 750 tons. The vessels are intended for the cargo-carrying trade between this port and Liverpool. They will run in opposition to the Belfast Steamship Company, and the competition is expected to have a good effect in reducing the present rates. Although there is no immediate prospect of dulness, workmen are much more plentiful and are easier to deal with than they were some months ago. Messrs. Harland & Wolff are still working a night shift in their engine department in order to keep pace with their work, and they are adding 100ft. to their magnificent fitting and erecting shop.

Irish Light Railways.—The Treasury have sanctioned a free grant of £115,000 for the construction of a railway between Donegal and Killybegs. This is the second scheme that has reached that stage under the recent Act.

The Linen Trade.—The Belfast linen merchants are now fully alive as to the probable effects of the American Tariff Bill, and business has already been seriously affected by it. Yarn sales have not been large, and the prices still remain firm. Cloth sales have also been small, but notwithstanding the small demand manufacturers do not seem inclined to reduce their prices. The shipment of goods to America has been considerably less this week. The flax crop so far promises to be very good this year, the weather ever since sowing having been all that could be desired.

Building Trade.—Upwards of 500 carpenters are at present on strike in Dublin for an advance in wages, but as many of the employers are inclined to concede to the men's requests, it is not expected to be of long duration.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 8d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week.

All accounts are payable to GEO. CAWLEY, *358, Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

FRIDAY, 13TH JUNE, 1890.

SYNDICATED INDUSTRIES.

THERE is evidently a pause in the movement which threatened, a short time ago, to force upon us artificial prices for many of the commodities that are used in arts and manufactures, due to the acquisition or control of such commodities by combinations of capitalists. A year or eighteen months ago this movement was at its high-water mark, and seemed likely to attain even more formidable proportions. Syndicates had been formed for the purpose of dominating the trades in steel rails, in copper, in tin, in flour, in pottery, in salt, and in many other commodities; while a combination of the coal owners of the United Kingdom, with a view to raising the price of coal, was seriously talked about. With the advent of better trade the occupation of the syndicate mongers seemed, however, to have gone. Prices improved nearly all along the line by the natural process of a larger demand. Some of the more promising syndicates, such as the copper ring, have meanwhile come to grief. The two influences, working together, and largely related as cause and effect, scared, at least for a time, the adventurous individuals who were seeking to get behind economic laws, and we will probably hear very little more of such syndicates for some time to come. It is well that this should be so. The new departure of syndicated industries and commerce threatened to deprive consumers of the benefits of the millennium of business that it promised to introduce. The history of the copper ring, which was terminated by a criminal trial, and by sentences that were certainly sufficiently severe to be deterrent, may be expected to point a moral that will affect the proceedings of syndicates and rings in the time to come. But the law of France is unlike that of most other countries, and the Code Napoléon visits with penalties, that are practically unknown elsewhere, any attempts to interfere with the natural and legitimate course of prices. It might be well if similar penalties were imposed in our own country on bodies of speculators whose sole mission in life appears to be to get up "rigs" and to make "corners," to found "trusts" and to establish "pools"—all of them designed and calculated to benefit a few individuals at the expense of the general public.

The recent considerable fall of prices in the iron and other trades is leading to new proposals, projects, and combinations, that aim at the regulation of prices or the monopolisation of commodities. Both in European countries and in the United States these organisations still continue to flourish, chiefly in the form of "rings," but also as "rigs" or "corners." The essential differences between these different forms of the species may be briefly examined. A "ring" usually differs from a "rig" or a "corner," in so far as it need not necessarily be speculative. The object of the corner is to secure large profits by a piece of financial or speculative engineering, at the expense either of the individual or of the community, and usually of both. The object of the ring may be simply that of regulating production—that is, of keeping supply and demand as nearly as possible abreast of each other—and so avoiding the violent fluctuations of prices that usually result from a different state of things. This was the plausible object of the ring known as the "regulation of the vend," which existed for a quarter of a century in the coal trade of the North of England. All the large coalowners pledged themselves, under that arrangement, to send to market only a certain quantity of coal, and while the declared aim of the combination was that of regulating supply it only affected prices incidentally. Prices were necessarily kept up by the limitation of supply, but not as a consequence of any definite agreement or pledge as to what they should be. Stated in its broadest and most comprehensive aspect, the design and aim of the ordinary ring or syndicate is to benefit the individual at the expense of the general community. From this point of view, the machinery, the processes, and the objects of a ring are alike indefensible. Of course, there are rings and rings, and the individual may be benefited without any ultimate detriment, but, on the contrary, with substantial advantage to the community. The community is made up of units, and while it does not, of course, follow that the gain of the unit implies the gain of the mass, it will be found in a general way that the welfare of the community is the welfare of the units that compose it. This is certainly true of the general results of industry and commerce. Let us take, as a case in point, syndicates or combinations for the purpose of regulating the production of manufactured commodities. If there is no over-production—if the demand just meets the supply—such a ring is quite uncalled for, and may probably do harm. But if the production exceeds the consumption by ever so small a quantity, there is an inevitable tendency to reduce prices beyond the paying point. Over-production is undoubtedly one of the great economic evils of the present day. It is not, however, entirely without compensations. So long as it stops short of reducing the profits of producers to absolute zero, it may even be a positive advantage, seeing that it secures a low range of prices for the multitude. If, as is often the case, these low prices are attended with real loss to the owners of works, mines, or factories, their advantages to the community are neutralised by the displacement of labour, the loss of employment, and the other economic difficulties which are involved. In the long run, the loss of the individual is generally the loss of the community, although the converse is not always equally the case. It is, therefore, better that prices should be so regulated as to allow of a fair margin of profit to the capitalist, than that profits should virtually cease. In the nature of things there must be an unsatisfactory end to a profitless business. Capital will be withdrawn from it, and labour will be transferred elsewhere. But at this stage the "ring" may come into play, and determine that the production shall be reduced so as to meet the demand as nearly as may be, or that the price shall be fixed at a certain minimum which brings about the same result in another way. The great objection to this process is, of course, that it is an interference with that freedom of trade which is so essential to healthy industrial development and national well-being. But it is certainly not a healthy condition of things when the production of a commodity greatly exceeds the consumption; and, being a more or less artificial malady, it may demand a more or less artificial remedy. In this dilemma, the choice has to be made between two evils. Over-production may be continued, with continued loss and ultimate disaster to the employer or capitalist, and starvation

Digitized by Google

wages to labour, or production may be regulated in such a way as to secure fair profits to capital, and adequate employment at fair wages to labour.

Regarded in this light, "rings" do not prejudice the community, if the parties to them are moderate in their demands. But unfortunately this is not always the case. All power is liable to abuse, and the power of regulating production and prices is no exception to the rule. It is only fair, however, to say, for industrial syndicates, that they are seldom found to abuse the enormous power that successful combination places at their disposal. To do otherwise would be to jeopardise their own future. It is the interest of a manufacturer to cultivate a permanent and stable trade. He is, therefore, interested in making such terms with the public as will induce the public to buy from him on the largest possible scale. This primary object would be defeated by the secondary and subordinate one of making the largest possible profit out of the public "while the game lasted." It is the commercial "corner" or "ring," and not the industrial, that acts on the principle of a short life and a merry one. There is a broad distinction between the two, and we cannot too soon recognise, or too strongly emphasize, it. The industrial syndicate usually seeks simply protection, and acts on the defensive. The commercial syndicate preys on the general community, usually without conscience, and heedless of consequences, while its action is distinctly aggressive. The distinguishing difference between "rigs" and "corners," and "rings" or "pools," is that the former are usually contrived by speculative individuals who are not themselves engaged in the trade, and may really know little or nothing about it, while the latter are originated by manufacturers or producers, as such. The "corner" or "rig" is also, as a rule, an operation of much smaller extent. The ordinary form of the process of "cornering" consists in buying larger quantities of any given commodity than the sellers are in a position to deliver. In other words, the seller, on purely speculative grounds, sells that which he does not possess, and cannot command if the "corner" is well managed. If, under such circumstances the speculator comes to grief, we need not waste much sympathy upon him. Buyers and sellers in "rigs" and "corners" are in much the same boat. Both are engaged in operations that are calculated to do infinite harm to legitimate trade. What is important is that this system of gambling has assumed serious proportions, and ought, if possible, to be restrained. There is hardly a leading commodity that is not more or less made the dice box of the "rig" and the "corner." The gaming tables of Monte Carlo are not more alluring, not more dangerous, not more subversive of public morality, and by no means so hurtful to society at large. The violent fluctuations of prices that are caused by these speculative movements seriously interfere with the natural and healthy course of industry, and restrain the operations of commerce. While commodities are oscillating between extremes of high and low prices, there is an inevitable disinclination, and even inability, to proceed with business in the usual way. The probable life of the "rig" or "corner" becomes the dominating factor in the situation, and, this being extremely uncertain, legitimate traders must, so to speak, grope their way in the dark. The "corner," pure and simple, is a conspiracy, and under the French law it is liable to be treated as such, and severely punished. Under our own more tolerant laws, it is permitted to flourish—if it can.

Another serious evil, which does not strictly come under the category of either "pools" or "corners," is the system, that has of late years attained large dimensions, of speculating in stocks of commodities such as pig iron, cotton, tin, copper, &c., in such a way as to force up prices at one time and depress them at another. This system has had a very remarkable influence on the course of certain of our leading industries. The stocks of these commodities are a known factor; but the extent to which they are made the basis for speculative operations is practically unknown. It is believed that the actual dealings in cotton and iron exceed by twenty or thirty times the actual quantities of these commodities, so that if deliveries of nominal purchases were insisted on there would be a general bursting of the bubble. Hundreds, and perhaps thousands, of persons regularly gamble in these stocks, without the least idea of *bonâ fide* purchases, and the legitimate trader is thus made a shuttlecock of a movement that he is powerless to diagnose or to control. A remedy is much wanted, but it is difficult to provide. Within certain limits speculation induces and bespeaks confidence, and so far it is a healthy influence; but such speculation as we have described usually does more harm than good.

AN IMPERIAL PENNY POST.

"First find your madman" is a saying attributed to the late Lord Derby. In this case the madman is Mr. Henniker Heaton. The word is not used in any offensive sense, either as originally employed or as now applied, for the uses of the enthusiast are too manifest to be gainsaid. The fanaticism of Sir Rowland Hill resulted in the penny post for the United Kingdom, as the fanaticism of Mr. Henniker Heaton seems likely to result in the penny post for the English-speaking people, and may be also for the civilised world. The universal penny post is indeed within measurable distance, for it needs no prophet to foresee that the natural result of an adoption of it by England would induce or compel France, Germany, and Italy to follow suit, in the same way that the twopence halfpenny postage policy of these countries has compelled England to follow them. If the imperial penny post becomes an accomplished fact, the letter-writer will owe a lasting debt of gratitude to the man who badgered the Post Office into granting it. His victory over the proverbial shortsightedness of the typical official was made very manifest in the concession made by Mr. Goschen, who has at last agreed to make an ocean postage of twopence halfpenny, at a cost to the Exchequer which may well be called insignificant—so manifest, indeed, that the final triumph of the penny post to the colonies can only be a question of time. The discovery that the loss to the Exchequer was so trifling is indeed one of those discoveries that anybody might have made, but that everybody in the official world, at any rate, delayed to make. When one has eliminated from the statements of Mr. Heaton the element of exaggeration in which he, as a politician, is prone to indulge, there remains sufficient solid basis of fact to found excellent arguments for the imperial penny postage. The gross anomaly of the circumstance that it was cheaper to forward letters to France for transmission to India than to post them direct from England to India being removed by the establishment of the twopence halfpenny post, the way is practically open for reduction to one penny. The argument that a large part of the sums paid in the name of postal subsidies is really paid for non-postal purposes is certainly a strong one. There is no reason why a large part of the cost of maintaining a naval reserve should be defrayed by the Post Office—that is, by the letter-writer—when, as matter of fact, the benefit is general, if benefit there be. Again, there seems no insuperable difficulty in obtaining a reduction of the rate from Calais to Brindisi, which at present is 1d. per letter, though the fact that the French and Italian Governments have both to be settled with makes it impossible to compare the rate so charged with the rate for conveying a letter across the American prairies. The strongest argument of all is that reduction of postage means increase of postage. The direct economic result has nearly always been favourable, and the indirect economic result has invariably been favourable beyond calculation. This alone affords overwhelming evidence in favour of an imperial penny post. The enormous increase in actual receipts which, as matter of fact, followed the adoption of a penny postage in the United Kingdom, is indeed a final argument in such cases, and when to this is added the undoubted gain in foreign trade following upon diminution of postal rates, it is hard to find a valid argument against the reduction. It may well be doubted whether a few years ago a penny imperial post would have paid, but the rapid rate of colonial growth places it almost beyond doubt that it would pay now, or at least would pay in the immediate future. Mr. Heaton's further contention that the State should take over the ocean cables is open, however, to serious objection. There are, certainly, national contingencies in which it might be advisable that the State should own the telegraph cables binding us to our remoter dependencies, but there is much to be said for an absolute neutralisation of the cables of the world, and this could never be under a system in which the cables belonged to any one nation. Besides, the companies, though they have in some cases, perhaps, maintained high rates, have, on the whole, served the public well, and the case against them would require to be presented in a much more potent way than that attempted by Mr. Heaton.

THE INTERNATIONAL CONGRESS ON INLAND NAVIGATION.

We understand from the *Manchester Guardian* that rapid progress is being made with the arrangements for the fourth International Congress on Inland Navigation, to be held in Manchester on the 28th prox. and following days. The meeting will be of special interest, both to visitors and to the people of Manchester, in view of the approaching completion of the Manchester Ship Canal. Visitors will naturally be anxious to see something of this great engineering undertaking, and the prospects of the canal will no doubt be improved by the publicity which it will thereby attain amongst the traders and the people generally of the various nations which will be represented. The objects of the conference are to promote the improvement of inland navigation and of estuaries, to direct attention to the economic value of navigable waterways, to examine generally technical questions relating to the construction and working of canals, to receive the report of the International Statistical Commission appointed at the last Congress, and to take further steps towards the collection of statistics bearing on inland navigation. The three previous Congresses were held respectively in Brussels, Vienna, and Frankfort-on-the-Main, and they were attended by delegates appointed by the Governments of the countries represented. The Board of Trade appointed Mr. Courtenay Boyle, C.B., and Mr. E. Leader Williams, C.E., to represent England at the Congress held in Frankfort in 1888. This year's conference is under the patronage of the Prince of Wales; Sir Michael Hicks-Beach, M.P., President of the Board of Trade, is president, and Lord Balfour of Burleigh, Parliamentary Secretary to the Board of Trade, deputy president. There is a very large and representative array of vice-presidents, headed by the Earl of Sefton, Lord Lieutenant of Lancashire, and there is also a strong general committee. The executive committee, on whom the bulk of the work connected with the arrangements for the conference will fall, is composed as follows:—Sir J. C. Lee, president; Mr. E. Leader Williams, chief engineer, Manchester Ship Canal Company, vice-president; the Mayor of Manchester (Mr. Alderman John Mark); Sir Edward G. Jenkinson, K.C.B., London; Mr. Courtenay Boyle, C.B., assistant secretary, Board of Trade, London; Mr. C. M. Kennedy, C.B., Foreign Office, London; Alderman Sir John J. Harwood, Manchester; Mr. L. F. Vernon-Harcourt, London; Mr. S. R. Platt, Oldham; and Mr. William Pollitt, general manager, Manchester, Sheffield, and Lincolnshire Railway Company, Manchester. Mr. J. H. S. Crompton has been appointed treasurer, Mr. Marshall Stevens honorary secretary, and Mr. A. A. Gillies secretary. Communications have been addressed to the Governments of Germany, France, Austria, Belgium, Italy, Spain, Holland, Norway and Sweden, Denmark, Switzerland, Russia, America, Portugal, and Greece, inviting them to appoint delegates to attend the forthcoming Congress. According to the programme which has been drawn up, the work of the Congress will be divided into two sections and sub-sections, and papers will be read as follow:—

Section I.—Engineering.

Sub-section 1.—Inland Canals and Canalised Rivers:—Subject A.—(a) Welland Canal; (b) The Aire and Calder Navigation; (c) The Weaver Navigation; (d) Volga and Baltic Navigation; (e) Present condition and development of inland waterways in England. Subject B.—Traction and propulsion on canals.

Sub-section 2.—Ship Canals and Tidal River Works:—Subject A.—Ship Canals: (a) The Manchester Ship Canal; (b) The Nicaragua Canal; (c) The Baltic Canal; (d) The Amsterdam Canal; (e) The Corinth Canal. Subject B.—The Improvement of Tidal Rivers:—(a) The principles of improving tidal rivers; (b) The action of tides and estuaries. Subject C.—Dredging and excavating.

Section II.—Trading and Economy.

Subject A.—Report of the International Statistical Commission.

Subject B.—The condition, management, and cost of working of inland navigation in France, Germany, Austria, Russia, Italy, Switzerland, Sweden, Netherlands, Spain, and Belgium.

Subject C.—The present position as regards finance and traffic of inland navigation in the United Kingdom, and what means can best be taken for its improvement.

Digitized by Google

Subject D.—The cost of transport on canals as compared with railways, and the mutual influence of railways and canals on each other.

Subject E.—The extent to which the State should assist or share in the development or management of inland navigation traffic.

The papers and the discussions which follow may be in English or French. It is intended to have on view numerous plans, maps, and models relating to inland navigation. At the Frankfort Congress a similar exhibition was held, the most valuable contributions coming from the German Government, who spent £4,000 on their preparation. It is hoped that these plans and models may be available for re-exhibition in Manchester. During the Congress excursions will be arranged to the ship canal and to a number of works and other places of interest in the North of England.

ACCIDENT TO THE S.S. "CITY OF ROME."

Another example of the utility of bulkheads has been afforded by the narrow escape of the transatlantic liner "City of Rome." On Friday last, during a thick fog, and although Captain Young and the other officers were taking every precaution, the ship struck the Fastnet Rock, situated on the west coast of Ireland. The look-out man observed the rock a short distance ahead, and the engines of the steamer were at once stopped and reversed, thus greatly reducing the force of the collision. Notwithstanding this, the shock was considerable, and created great excitement on board, which, however, was soon allayed when it was found that there was no immediate danger, the ship having backed into deep water and floating buoyantly. It was found that the stem was smashed and badly twisted, and the forward tank filled with water. On ascertaining the actual state of affairs the captain gave orders to steam ahead at half-speed, which was done in the midst of a dense fog. There were nearly 1,000 souls on board, and of these 133 disembarked at Queenstown, the majority proceeding with the ship to Liverpool, which she did at half-speed. If the ship had been going at full speed at the time she struck, or if she had been without proper bulkheads, it is probable that there would have been great loss of life. A great deal is due to Captain Young for the precautions he took, and for his skilful action in trying circumstances, and the passengers took occasion to show their appreciation of his services by presenting him with a testimonial.

RAPID BRIDGE ERECTION IN GLASGOW.

The increasing traffic in connection with the Caledonian system has made it necessary that additional lines should be laid into the Central Station. Some time ago the iron girder bridge across Argyle Street was widened, and a new station erected at Bridge Street. In order to complete the work it was necessary to widen the track in Eglinton Street, and this offered considerable difficulty. At a point about half-way down this section of the line the Caledonian is crossed by the Glasgow and South-Western Railway, and it was necessary to remove the overhead bridge and put a new and longer one in its place in twenty-four hours after midnight on a Saturday. The contract was taken by Messrs. William Arrol & Co., and the erection of the bridge was carried out under the personal superintendence of Sir William Arrol. Operations were commenced last Saturday night by the removal of the old permanent way. This part of the work was completed in about three hours. The old and the new bridges were braced together, and by means of powerful hydraulic rams both structures were simultaneously moved northwards, the old to the platform, and the new to the position formerly occupied by the old, an operation which was performed in less than four hours. The beds for the ends of the girders were then prepared, the girders lowered into their positions, and the permanent way relaid. The whole of the work was done by four o'clock on Sunday afternoon—that is to say, in about sixteen hours, or two-thirds of the stipulated time. The necessary Government inspection was made in the afternoon, and the Greenock train passed over the new bridge in the evening. The work which was thus rapidly executed is one of the most interesting pieces of railway engineering yet carried out, and shows what can be accomplished by good planning and by utilising the powerful appliances which are now within the reach of the engineer.

Letters to the Editor.

THE LANE-FOX PATENTS.

To the Editor of "Industries."

Sir,—I enclose for your information a copy of a letter which we are sending out to all undertakers using the Lane-Fox system of distribution, offering them terms for using the patents.

As to private installations, a circular will be issued shortly in much the same words, but substituting for the charges given A, B, and C, a royalty of 3s. 6d. per 16 c.p. lamp per annum.

Yours, &c.,
C. A. Stephenson,
Managing Director, Lane-Fox Electrical Company, Limited.

2, Prince's Mansions,
66, Victoria Street, London, S.W.,
10th June, 1890.

"Dear Sir,

"1. You are doubtless aware that your company is making use of the Lane Fox patent for electrical distribution, No. 3988** of 1878.

"2. This patent, together with all the Lane-Fox patents, are now held by this company.

"3. My object in writing is to inform you that this company is prepared to grant a licence to your company, as undertakers; and I have to offer the choice of the following methods of payment of royalty for the use of the patent:—

"(A) By a payment of ½d. per Board of Trade unit supplied to consumers.

"(B) By a payment of ⅛d. (one-eighth of a penny) per Board of Trade unit supplied to consumers. Such payment to continue after the expiration of the patent for such a term as would render the payment equivalent to A, taking all risks into consideration.

"(C) By a capitalised sum, payable partly in cash, partly in shares of your company; the sum to be arrived at on the basis of A.

"4. On an agreement being entered into we shall be prepared to give your company as undertakers an indemnity for having used the patents prior to 31st December, 1889.

"5. This company will also consider such an agreement as final, and will not make any further claim in respect of any patents for distribution, regulation, secondary batteries, and motor-dynamo distribution, taken out by Mr. Lane-Fox during the years 1878 to 1883.

"6. You will understand that these terms are offered without prejudice: no period is at present definitely fixed within which we shall require your acceptance; but this company reserves to itself liberty to withdraw these proposals at any time after the 16th inst.

"Yours faithfully,
"C. A. Stephenson,
"Managing Director, Lane-Fox Electrical
"Company, Limited."

BRITISH MANUFACTURES ON THE CONTINENT.

To the Editor of "Industries."

Sir,—Your correspondent "Trader" partially attributes the scantiness of business done by this country on the Continent to our customs being different from theirs. I am more inclined to reverse the theory, and say it is because their customs are different from ours. The matter lies more in Continental protective duties than the inability of British business men to push their wares.

Yours, &c.,
T. R.

London, 9th June, 1890.

PIECE WORK.

To the Editor of "Industries."

Sir,—I do not quite follow "A Former Mechanic" in his argument. That workmen overdo their strength in piece work and put forth strenuous exertions which would kill them, and are only saved from death by the fact that the employer reduces wages, and thereby causes them to work less hard, is a matter which I very much question. "A Former Mechanic," I notice, hails from Glasgow. I also am a former mechanic, and my experience was also gathered in the North—viz., in Edinburgh. I should say that such questions stood on much the same ground in both cities, but I never came across men rushing it too hard at piece work. I also do not know what he means when he says that under a bad employer piece work degenerates into task work. Time work is also task work. With the writer's expression of opinion as to the education of apprentices I can cordially agree.

Yours, &c.,
J. D. W.

Birmingham, 7th June, 1890.

Reviews.

Gas and Petroleum Engines: A Practical Treatise on the Internal Combustion Engine. By William Robinson, M.E., Senior Demonstrator in Applied Physics and Electrical Engineering in the City and Guilds of London Technical College, Finsbury; Assoc.M.Inst. C.E., &c. London and New York: E. & F. N. Spon. 1890.

This is a work which supplies a decided want in English technical literature. Gas engines, it is true, have been previously dealt with by other authors, but a coherent treatise on petroleum and like motors has not hitherto been forthcoming, nor has the subject of gaseous fuels and the modern appliances for their production been taken up in a concise and practical manner by elementary text-books. This has now been done by Mr Robinson in the work before us. With regard to gas engines, although, as we have hinted, the subject is not a new one, yet, as far as we remember, the latest book on that class of engine is several years old, and since it was published many new kinds of motors and improvements of those previously in existence have been introduced, so that the work is no longer up to date. In this latter respect we may say at once that Mr. Robinson's treatise leaves nothing to be desired.

After a short introduction in Chapter I., the author first proceeds to consider, in Chapter II., "The Action in the Otto Gas Engine." At the commencement he states that he has arrived at the conclusion that the best way of presenting the subject of internal combustion to his readers is to describe carefully the action of some particular form of gas engine, since the ordinary reader would have some difficulty in understanding the significance of certain points in the history of this class of motor unless he were acquainted with the working of one at least of the best modern forms. Accordingly, the author gives a very full account of the construction and working of the Otto engine, as made by Messrs. Crossley Bros., Limited, with numerous illustrations of the various details, general construction, and indicator diagrams. In Chapter III. "Modifications of the Otto Type of Gas Engine" are dealt with, but under this heading are comprised only the Atkinson and the "Simplex" gas engines, other modifications being described in Chapter VI. under "Classification of Internal Combustion Engines." The reason for this separation is perhaps not very evident, and seems scarcely logical, but as there is a good index the matter is unimportant.

With Chapter IV. we come to the "Uses of Petroleum in Prime Motors." Here we find descriptions of the "Priestman" and "Spiel" petroleum engines of the latest types, with copies of indicator diagrams; also of the so-called "Zephyr" launch engines, using hydrocarbon vapour both as fuel and working agent, and the "Bailey-Friedrich" petroleum steam motor, using petroleum as fuel.

The history of combustion and caloric engines is next briefly sketched, and brought up to date in Chapters V. and VI., in the latter of which modern types like the "Stockport" and "Griffin," of course, receive fuller attention than such as have now become obsolete. The author in this portion of his work refers to what he calls an "Ideal Regenerative Engine," proposed by Professor Fleeming Jenkin in a paper read before the Institution of Civil Engineers, and in connection therewith points out "that the regenerator can only store up as much of the heat left in the rejected fluid when the exhaust opens as will cool this to the temperature of the fluid entering from the pump. . . . . Of course the temperature of the incoming gases cannot be raised by the regenerator above that to which the previous charge was reduced by expansion in the motor cylinder." This being the case, we think Mr. Robinson should have added, that the best which can be effected by an ordinary regenerator is only equal to the best that is possible without it. It is, in fact, merely a device for supplementing the deficiencies due to incomplete expansion.

To the various methods of firing the explosive charges in internal combustion engines a separate chapter is devoted, the author arriving at the conclusion that ignition by the electric spark is, when properly carried out, the most satisfactory and economical. Perhaps one of the most valuable portions of Mr. Robinson's book is that in which the relative heating values of solid, liquid, and gaseous fuels are given, with particulars of the methods of production and composition of various kinds of gas, such as "Dowson," "Wilson," and oil gas of different descriptions. What is known about dissociation, rate of flame propagation, and explosion in a closed vessel at constant volume is concisely stated in Chapter XV., together with the results of Professor Witz's experiments on the cooling action of the cylinder walls when, after ignition, an explosive mixture expands while doing work.

The final portion of the book deals with trials of gas motors, and among other matters shows how a heat balance should be made out. The accounts of experiments with motors here given do not, however, include all that the author has to say upon this subject, for in various places the results of trials are quoted, more or less in detail, in connection with descriptions of different types of engines.

We have been able, within the restricted space at our disposal, to give only a very inadequate idea of the large amount of information, presented in a useful and practical form, which the author has collected within the 596 pages of his book. Those who are at all interested in gas and petroleum engines cannot do better than make themselves personally acquainted with its contents. The work forms one of the "Finsbury Technical Manuals," and is edited by Professor Silvanus Thompson.

SPON'S ENGINEERS' DIARY AND REFERENCE BOOK FOR ENGINEERS, MACHINISTS, CONTRACTORS, AND USERS OF STEAM FOR 1890. London: E. & F. N. SPON.

This diary is likely to prove useful to the classes for whom it is intended, containing as it does a variety of useful information, but the way in which the advertisements are mixed up with the letterpress will detract somewhat from the ease of reference. It contains an engineering trades report to 30th June, 1889; calendars for 1890, 1891, and 1892; tables connected with the metric system of weights and measures, and also for thermometers and hydrometers, as well as very extensive tables giving the English values of foreign moneys, and the English values of foreign weights and measures. There are also wages tables and tabulated statements of the iron and steel trades of Great Britain, and of the iron ores raised during the years 1886 and 1887, together with imports of iron ores and countries from which they come, and tons of coal exported, with their destinations. There is an interesting article on the depreciation and valuation of factories. A list of legal decisions, relating to engineering, is given; but this is very incomplete, some of the decisions given having no special interest for engineers, and many which are of importance being left out. No decisions relating to patents are mentioned at all, and these we should expect to find under this heading. Very useful features are the lists of recent technical literature, comprising lists of books recently published on all subjects in any way connected with engineering; the list of papers presented to Parliament, including a list of the Acts of Parliament relating to engineering; lists of recent reports of the Board of Trade and Mercantile Marine, and of the Local Government Board. Under the head of Engineering and Allied Societies will be found an account of the various societies both in London and the country, with a list of the papers read recently before each society. The book concludes with information concerning the various engineering examinations, and a list of the engineering and technical schools throughout the country; the full regulations relating to the Whitworth scholarships; and tables relating to patents, designs, and trade marks in various countries. The diary is neatly bound, and of a size convenient for easy reference.

CHRONOLOGICAL, HISTORICAL, AND HERALDIC CHARTS OF THE ROYAL HOUSE OF ENGLAND FROM KING EGBERT TO THE PRESENT TIME. By I. A. Timmis, M.Inst.C.E. London: HENRY SOTHERAN & Co. 1890.

This regal volume consists of a series of chronological and heraldic tables illustrated with memoranda of historical events and notes from monumental effigies and inscriptions. Heraldry is so little studied nowadays that the means it affords of throwing light upon historical events are apt to be overlooked. Copious charts like those of Mr. Timmis are very useful to students of history, who are too apt to specialise upon a period, and are thus inclined to lose sight of the need of co-ordination. When read alongside of Mr. George's tables, those of Mr. Timmis are extremely instructive, for they show at a glance to the careful reader the line of descent of many of the chief families of England and Germany. The arms are admirably executed, and the work throughout is most carefully arranged.

Legal Proceedings.

CROMPTON AND CO. *v.* THE ELIESEN ELECTRIC LIGHTING COMPANY, LIMITED.

THIS action was tried before Mr. Baron Huddleston and a special jury. The plaintiffs claimed £384, the balance due to them under a contract into which they had entered with the defendant company to furnish plant and equip a station for the working of the defendants' system of electric traction, which was to be employed upon a part of the line of the North Metropolitan Tramways Company. The defendants admitted the claim, but relied upon a counterclaim which they made against the plaintiffs for loss of profits and injury to their trade, resulting, as they alleged, from the plaintiffs' negligence and failure properly to carry out their obligations under the contract.

The matters in dispute involved some important questions of law and fact, and the case is of interest as illustrating how very closely the functions of a contractor may approximate to those of a manager. The facts of the case, so far as they are material to the decision of the case, were as follows:—In the year 1887 the defendant company acquired the plant of the Electric Locomotive and Power Company, and also took over a contract with the North Metropolitan Tramways Company for running two tramcars between Manor Park and Stratford by electric traction. They began running the cars in the beginning of August, 1887, and continued running them until the middle of March, 1888. During that time the running of the engines had been perfectly satisfactory, not more than twenty or twenty-five journeys having been lost throughout the period. In March an understanding was come to that the system should be extended, and on the 19th of that month the running of the electric cars was stopped, because it had been found unsafe to take them over a temporary cross-over that had been made by the tramway company. It was then arranged that the running contract between the tramway company and the electric power company should be suspended, or rather it was terminated by mutual consent, but on the understanding that a new contract would be entered into when the electric company was prepared to resume operations on an enlarged scale. By way of preparation for this resumed and enlarged operation, it was arranged that the company's station should be removed to a place known as Plashet Hall, and a contract was made with Messrs. Crompton & Co. to undertake the preparation and equipment of the new station. As to the nature of this contract the first question arose. On the part of the defendant company it was contended that Crompton & Co. had undertaken as principals to do what was necessary, and had, for the purpose of enabling them to carry out their engagement, been placed in possession of the defendants' property. On the part of the plaintiffs it was contended that the arrangement amounted to no more than the undertaking by Crompton & Co. of the duties of managers of the defendants' business *ad interim*, and that the responsibilities which they undertook was a responsibility to manage with reasonable skill and care, but not a responsibility for the acts or defaults of subordinate persons who had not ceased to be servants of the defendant company.

This strange discrepancy could not have arisen had the customary precaution of drawing up a written agreement been adopted; but in point of fact the parties had been content with a mere verbal understanding. Heads of agreement had been settled between the firm and the secretary to the company, and these heads had formed the basis of a discussion which had taken place at a board meeting of the company which Mr. Crompton had attended. The results of the discussion had moreover been embodied in a minute, and both the draft and the minute were produced in court. On the part of the plaintiffs it was admitted that the draft expressed the agreement come to, and upon comparison it appeared that the minute did not materially differ from the draft. There was, however, no written agreement executed between the parties, and in this state of the evidence the learned judge left it to the jury to determine what the exact nature of the agreement was. If the position taken up by Crompton & Co. was that of managers, they would be responsible only for their own personal negligence and for errors of management. If, on the other hand, the plaintiffs' position was that of principals—that is to say, independent contractors—they would be liable in respect not only of their own negligence but of the negligence also of any servant whom they had employed.

The negligence complained of resulted in the following mishaps. When the running was resumed in September, 1888, several breakdowns occurred, with the result that the tramway company revoked the permission which they had granted to the electric supply company to recommence driving cars, and desired them to desist from so doing until their plant was in perfect order and the company prepared to undertake afresh the full responsibility of working under contract. This circumstance afforded ground for the defendants' counterclaim, and in support of it three specific acts of negligence were relied upon at the trial—(1) the motor had broken down in work through failure of the current supplied by the accumulators; (2) a pair of engine wheels had been broken in passing over the points which connected the main line with the station siding; (3) a spur or crown wheel, with which the pinion of the dynamo geared, had suffered fracture of several teeth in use, and so had become incapacitated for further employment. These various accidents had not only caused the engines to lose several journeys during the three days of experimental running, but had so disorganised the traffic as to cause the discontinuance of the experiment as above explained. Upon this basis the defendants claimed damages £10,000, being the estimated value of the damage done to their business by the unsuccessful result of the experimental working.

On the part of the plaintiffs it was contended, in the first place, as already intimated, that they were liable not as principals, but as servants or managers to the defendants; but that even if liable as contractors, they would be liable only for the immediate and not for the ulterior consequences of any breach of the contract, and in this contention they were upheld by the learned judge, who directed the jury that in a case of broken contract the true measure of damage was the cost of replacing what was injured, or of supplying what was deficient at the market price, unless it were clearly shown that some other and further consequences of the breach were clearly in the mind of the parties at the time of entering into the contract, and this on the broad ground that it was not fair that a man should be paid for performing a contract upon one basis, and mulcted for its non-performance upon another. The defendants' proof of damage was accordingly restricted to the direct and immediate loss, such as loss of earnings and cost of repairs.

In reference to the giving out of the accumulators, the plaintiffs chiefly relied upon the broad ground of their having acted as managers, and being, therefore, not liable for an act which, if an act of negligence at all, as for example, the omission to charge the accumulator properly before commencing work, was the act of a subordinate. Upon this head the jury found against the plaintiffs, determining that they had undertaken the work as contractors, and that they were, therefore, liable for the defective condition of the accumulators. On the second issue, that of the defective points, the plaintiffs contended that they were not liable for this because the point had been laid by another contractor, who was employed and paid, not by the plaintiffs, but by the defendants, and this contention prevailed, the jury finding for the plaintiffs on this issue.

The breaking of the wheel teeth gave rise to much discussion, being attributed by the defendant company to the non-use by the plaintiffs of a special reversing switch which the inventor of the Eliesen motor had provided for reversing his motors, and by the plaintiffs to inherent defects in the Eliesen design. It was, however, admitted by Mr. Chamen, the engineer put in charge of the Plashet Hall Works by Messrs. Crompton, that he had been content with repairing some of the teeth of this wheel which were obviously defective, whereas it would have been wiser for him to replace the wheel, and that had he taken this precaution the accident complained of would not have happened. The jury, adopting this view, found for the defendants upon this issue also, and in the result awarded to them £184 upon their counterclaim.

Judgment was given in favour of the plaintiffs for the balance of £200, and the costs of the claims, the costs of the counterclaim being awarded to the defendants. The counsel appearing were—for the plaintiffs, Mr. J. Fletcher Moulton, Q.C., and Mr. J. C. Graham; for the defendants, Mr. Finlay and Mr. Bousfield.

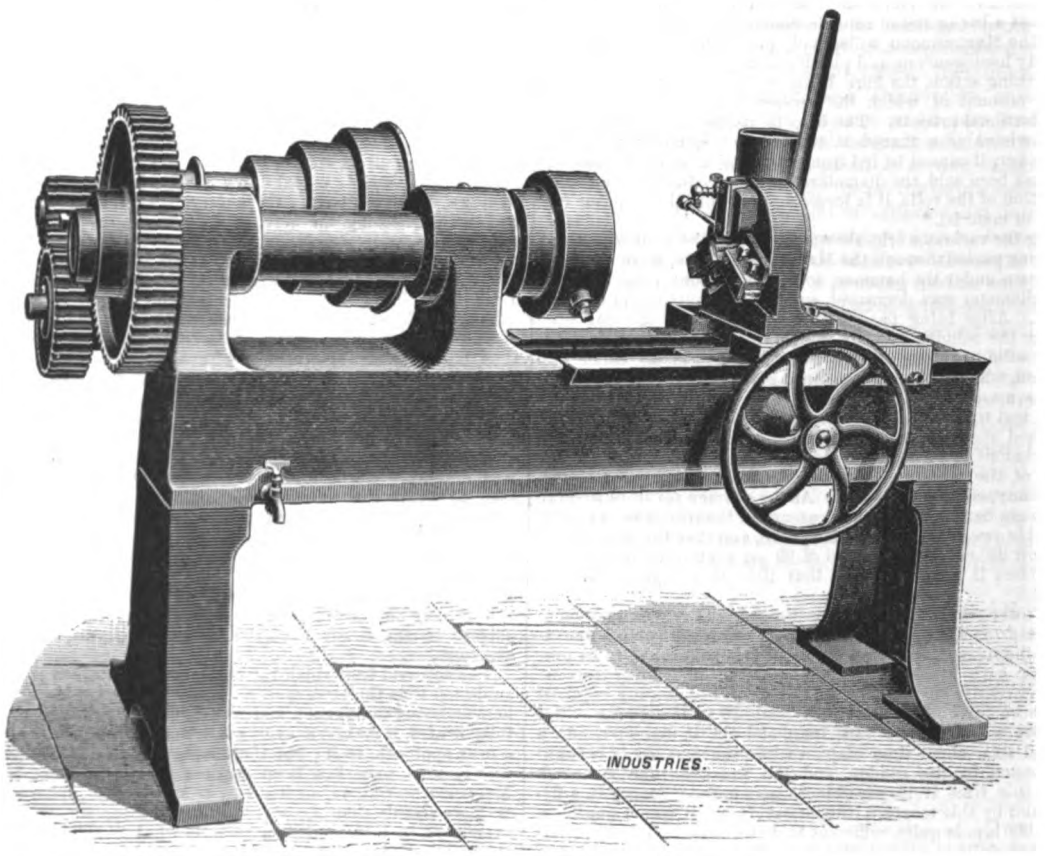
AGRICULTURAL SHOW AT ROCHESTER.

As we briefly mentioned in our London letter of last week, there was opened on the 5th inst. at Rochester the annual show of the Bath and West and Southern Counties Society for the Encouragement of Agricultural Arts, Manufactures, and Commerce. The show ground was in a very favourable position, between Chatham and Rochester.

Amongst the heavy machinery Messrs. Aveling & Porter, of Rochester, had a good display of agricultural locomotives, together with a traction engine combined with an Anglo-American Brush Victoria dynamo. This engine was of 6 nominal h.p., but the output of the dynamo was not obtainable. The same firm also showed a steam road roller weighing 10 tons when empty. The Kentish Engineering Works, Maidstone, whose title used to be Drake & Muirhead, had a large display of hop washing and other hop machinery. A new hop washing engine was shown, in which compressed air is used in combination with liquor, and the proportions being adjustable, either a moderately fine spray or an atomised mist can be produced. Among the exhibits of Messrs. Henry Bamford & Sons, Uttoxeter, Staff., were their reapers and mowers, and a large variety of corn grinding mills for various powers. Messrs. Howard, of Bedford, in addition to ploughs, harrows, and rakes, showed haymakers, a light steel frame sheaf binder, and their well-known hay trusser. A self-regulating windmill was shown by Messrs. Duke & Ockenden. The turntable is made of chilled iron, and revolves on sixteen anti-friction balls. A good display of milling machinery was shown by Mr. Simeon Howes, 64, Mark Lane, E.C., in addition to a "Little Giant" turbine. Mr. Percy J. Neate, 16, St. Margaret's Bank, Rochester, had a collection of general machinery. Messrs. Fielding & Platt, Atlas Works, Gloucester, had a vertical gas engine, which has no slide or ignition valve, and only one valve under pressure; a single cam works the valve gear. Messrs. Hornsby had a large display of engines, hay trussers, reapers, mowers, and small implements. They had also two "strawsonizers" of 1 h.p. each and one hand "strawsonizer." It will be remembered that we gave an illustration of the first one which was made in our issue of the 9th of November, 1888. A hop washing machine was shown by Mr. W. Lambert, Hazel House, Horsmonden, Kent. Special jets are used, which allow the water being dis-

Digitized by Google

charged in a very fine spray, and the same apparatus can be used as a fire engine by the attachment of a hose. The same inventor has a steam power machine for cutting hop bines into litter. Messrs. W. & T. Avery, Digbeth, Birmingham, have some novelties in weighing machines. One of these is a combination weighing machine to carry up to 30 cwt., and another weighing machine and waggon to carry 50 cwt. If required these can be made self-registering. There was also a steelyard, in which the weight is mechanically registered on a slip of cardboard, and in combination therewith there is an electric registering indicator. The latter portion of the machine was, however, not at work at the show, as the battery had been broken in transit. In another part of the yard there was also seen a weighing crane to lift up to a ton. This crane weighs the load carried rapidly and with great accuracy.



Among heavy machinery there may be briefly mentioned Messrs. Marshall, Sons, & Co., Limited, of Gainsborough, who had an 8 h.p. traction portable steam engine, thrashing machines, and chaff cutters. Messrs. Ransomes, Sims, & Jefferies, of Ipswich, had an 8 h.p. portable, a 6 h.p. agricultural locomotive, and a thrashing machine and straw trusser. Messrs. J. Fowler & Co., Limited, of Leeds, had one traction engine of 8 nominal h.p. for general purposes, of strong design. Messrs. Chas. Burrell & Sons, Limited, Thetford, had an 8 h.p. road locomotive and traction engine, and a thrashing machine, besides smaller machinery. Messrs. Wallis & Stevens made a smaller display, and Messrs. Clayton & Shuttleworth, of Lincoln, had a large stand of their ordinary productions. Messrs. E. & H. Roberts, Deanshanger Iron Works, near Stony Stratford, showed the well-known "Premier" elevator, while Messrs. Ruston, Proctor, & Co. confined themselves to an 8 h.p. traction engine and a thrashing machine. A large display of corn screens was made by Messrs. W. Rainforth & Sons, Lincoln, and Mr. Richard Batchelor, Artois Works, Chatham, had an excellent display of boring machinery for artesian wells. Messrs. Barrows & Co., of Banbury, Oxford, had a new street sweeping machine, in which a new spring clutch arrangement is conveniently placed for the driver to throw the working parts of the machine out of gear by using one lever, and without stopping the horse. Messrs. W. H. Willcox & Co., 36, Southwark Street, S.E., exhibited a drilling machine, fitted with a combined parallel vice and revolving chuck plate. The plate is divided and provided with steel jaws along the whole length of the diameter. The necks are conical, and revolve in conical sockets, which allow the jaws to grip taper or other work. The object is to supersede the usual revolving cast-iron tables, carrying a vice on one side and plate on the other, and, to do away with having to bolt parallel vice on the plate, the vice-plate is self-centreing. Mr. Sidney W. Gibson, Eynsford, Kent, shows an improved marking machine to meet the requirements of fruit growers and market gardeners. It allows of the line being cross-marked, so that in planting out the plant can be set in each corner like sets. Messrs. Henry S. & F. Tett, Preston Works, Faversham, had a simple two row one-horse drill. The front shares can be easily raised or lowered. Mr. John N. Davies exhibited a revolving divider for use in connection with all kinds of manual and heavy delivery reaping mowers and with sheaf-binding harvesters. Its object is to avoid the difficulty occasioned by tangled straw hanging on to the divider and drawing the off end of the machine into the ground. The Standard Manufacturing Company, St. Alkmund's Churchyard, Derby, had some very effective tree pruners, which were shown at work. The knives were worked by ratchet gearing from the foot of the pole, and the cuts were very rapid, cutting branches over 2in. in diameter. Messrs. Taylor & Neate, Medway Works, Rochester, had mill hursts, plunger pumps, and a specimen of the Cyclone pulveriser, which was noticed on its introduction to this country in our journal (see Vol. IV., page 566). An iron mast case for barges, which was exhibited, has winches arranged so that one side can be worked independently of the other. In the same firm's screw-cutting gear a universal trunnion joint is employed at the after extremities of the connecting rods, and in the attachment for the heavy bearing for the steering shaft.

Messrs. Balls Garrett, Medway Iron Works, Maidstone, had a large collection of machinery, a large part of which was Messrs. Richard Garrett's make, and others by Howard, Samuelson, and Hornsby. The result of both principals and agents exhibiting at the same time at the show resulted occasionally in the duplication of exhibits, which only tends to confusion. Small vertical and horizontal engines were shown by Mr. G. S. Hindley, of Bourton; gas engines by Messrs. Crossley and Messrs. Andrews; and a portable petroleum engine by Priestman Brothers.

Butter making competitions were held during the course of the show.

IMPROVED SCREWING MACHINE.

CONSTRUCTED BY MESSRS. LISTER & CO., ENGINEERS, KEIGHLEY.

IMPROVED SCREWING MACHINE.

WE give above an illustration of a new screwing machine, made by Messrs. Lister & Co., engineers, Keighley, which is capable of forming screws from ½in. to 1½in. diameter. As will be seen, the driving spindle carries a four-step cone, and is connected to the machine spindle by gearing. This arrangement allows a considerable variation of speed. The spindle is of hollow steel, with conical front bearing running in gun-metal, and having a centre grip chuck. Improvements are embodied in the die holder, the die boxes being of wrought iron case-hardened, with large wearing surfaces, and front supports as a safeguard against cutting pressure. Straight dies can pass through, fastened by set screws, so that the dies may be set up and recut many times. As they are only straight pieces cut from the bar, they require a minimum of work when recut or replaced. The dies being in front of the die-head allow the cuttings to get freely away.

THE MANNESMANN PROCESS FOR MAKING SEAMLESS TUBES.

WE described this process in our issue of the 30th March, 1888, when it was first introduced, and we now give an abstract of an interesting paper on the process by Mr. J. G. Gordon, read before the Society of Arts, on the 21st ult., as this mode of tube-making is likely to form an important industry.

For the conveyance of water, gas, oil, and steam, for warming and ventilating dwellings and other buildings, and in the construction of all sorts of engines and boilers, as well as for the transmission of power by means of water or air, and last, but not least, for the construction of all sorts of firearms, from the 110-ton gun to Colt's Derringer, tubes are indispensable; while at the same time engineers are turning more and more attention to tubular forms for many parts of structures, as they pre-eminently combine lightness with strength. Before the beginning of this century the use of tubes was comparatively small. Apart from conduits for water, which were generally made of tree trunks with a hole bored through them, as some recently dug up in Harley Street show, when they were made in the form of pipes at all, the main use of tubes, or more strictly speaking, of metallic tubes, was for parts of firearms.

The process of manufacture of welded wrought iron and steel tubes consists first in making a strip of metal of the length of the tube required, and rather wider than the circumference of the tube required. This strip of metal is heated to a welding heat, and then bent by machinery into a tubular form. It is then welded either by means of hammers, by drawing through a die, or by being passed between rolls of appropriate section, and much skill and ingenuity have been devoted to the perfecting all the details of this complicated and difficult process, with the result that now such wrought iron or steel tubes can be obtained in almost any quantities, and at prices which, compared to those which were formerly paid, are very moderate. But although the wrought iron and steel welded tubes are both cheap and good, they had, and still have, a weak point—namely, the weld. It is here that they are generally found to give way under any severe strain, besides which, above and below certain diameters—that is, below about 1in. and above about 6in. or 7in.—the difficulties of the manufacture of welded tubes are much increased. This difficulty in making tubes of large diameter has been overcome, to some extent, by riveting together plates bent into a tubular form, but this is necessarily a costly process, and considerable difficulty is experienced in making the riveted joints perfectly tight. It has therefore been the aim of many inventors for the last thirty or forty years to produce weldless or seamless steel and iron tubes, and a considerable number of processes for producing such tubes have been devised, and many patented in this and other countries, by means of some of which at the present time considerable quantities of weldless tubes of high quality are being produced. The Mannesmann process is one of these latter processes. It has already been described in a paper by Mr. F. Siemens, read before the British Association at their Bath meeting in 1888, in which that gentleman pointed out the salient features of the new process.

The Messrs. Mannesmann produce weldless or seamless tubes of steel, or any other ductile metal, such as copper, bronze, delta metal, lead, or aluminium, by rolling them in skew-rolls—that is to say, in rolls which are not parallel either to one another or to the bar or other material to be treated by them.

In the ordinary rolls, the bar to be rolled is put in at right angles to the rolls, which revolve in opposite directions. But in the Mannesmann tube-mill both rolls revolve in the same direction, and the bar to be acted upon is placed between them lengthways, while, as before mentioned, the axes of the rolls are not parallel to one another. A tube in front of the rolls acts as a guide for the bar, which is pushed in between them. These rolls revolve at about 200 to 300 revolutions per minute, and by their action on the hot and therefore plastic steel, stretch it, and make a hollow in the centre. To explain why the rolls acting in this peculiar manner have the effect on the bar of steel subjected to their action of converting it into a tube, I cannot do better than to quote from the paper by Mr. Frederick Siemens already alluded to. He says:—

"To obtain a simple forward spiral action of the bar, the length of the rolls is immaterial; it will take place when the rolls are reduced to the form of thin discs. Supposing the discs to be infinitely thin, or, what is the same thing, that their outer edges are reduced to a mathematical line and no sliding motion takes place, the bar must still move forward spirally, its spiral velocity being equal to the velocity of the outer circumference of the discs. If, instead of one pair of such thin discs, several pairs of discs of regularly increasing diameters are made to revolve on the same axis, the outer circumference of each disc will revolve with greater velocity than that of the preceding one. The same bar is, however, drawn forward through the several pairs of discs, and thus as each part of the bar enters successively a more advanced pair of discs, the velocity with which that portion of the bar rotates increases, and it is drawn forward by each succeeding pair of discs as they catch hold of it with ever-in-

Digitized by Google

creasing speed. It will be understood that a bar passing through such a series of discs, no slipping being possible, the material of which it is composed cannot retain its original area or volume. The diameter of the bar being regulated by the discs, while simultaneously a violent stretching action is carried on, the material required can only be drawn from the inside of the bar, and thus a hollow space is formed.

"Instead of this peculiar arrangement of discs a conical, or rather conoidal, pair of rolls, which amount to the same thing as the discs, considered as joined together, may be provided. It follows that a bar or rod of suitable dimensions, which is passed through the Mannesmann rolls, will, provided its substance is sufficiently homogeneous and plastic, undergo a violent twisting and stretching action, the fibre being spun as is the fibre in a rope, on account of which the process may appropriately be called a tortional process. The bar, in its passage through the rolls, is twisted as a thread is twisted in a spinning machine. As, however, it cannot be fed from the outside as is the thread, and, as has been said, the diameter cannot be reduced on account of the action of the rolls, it is forced to draw on the interior for a supply of material."

Among the various works shown was a bar, the ends of which, before being passed through the Mannesmann rolls, were slightly drawn down under the hammer, so that for about 1½in. at both ends its diameter was decreased, so that the rolls could not act on them. After being passed through the rolls the bar was broken in the middle, and, as shown, a tube had been formed from the solid bar along all that part of its length on which the rolls acted, while both ends remained solid. A hollow produced thus in a massive steel bar should be a perfect vacuum. In order to test this, Messrs. Mannesmann sent several such tubes with closed ends to Professor Finke, in Berlin, who devised a most ingenious apparatus for testing both the pressure in the interior of the tube, and also the chemical composition of the gases, if any, contained therein. As the average result of several experiments he found that the pressure in the tube was as nearly as possible one-tenth of an atmosphere, and that the gas which the hollow did contain consisted of 99 per cent. of hydrogen, and he considers it most probable that the other 1 per cent. was nitrogen.

The power required to produce the tubes is very large, something like from 2,000 h.p. to 10,000 h.p., according to the dimensions of the tube. If a steam engine of this power had to be provided for each machine, the plant would of course become extremely costly, but, luckily, this great power is only required for a short time. For each tube made 30 to 45 seconds suffice to convert a bar 10ft. to 12ft. long, and 4in. in diameter, into a tube, and then some time elapses while the next bar is brought up, adjusted in the guides, and the finished tube removed. During this time it is possible to accumulate energy in a fly-wheel, and by this means a comparatively small steam engine of about 1,200 h.p. is quite sufficient to do the work. The fly-wheel differs materially in construction from those ordinarily in use, and was designed by Messrs. Mannesmann to guard against the terrible danger of bursting, to which accident cast-iron fly-wheels are only too subject when worked at a high speed. This wheel consists of a cast-iron hub, to which are securely bolted two discs of steel plates of about 20ft. in diameter; round the periphery of the wheel thus formed about 70 tons of No. 5 gauge wire are wound under a tension of about 50lb., thus binding the whole securely together. There can be no comparison between the resistance of a wheel so constructed to the centrifugal force and that offered to this force by a cast-iron one. This fly-wheel, of 20ft. in diameter and weighing 70 tons, revolves 240 times per minute; therefore, the periphery of the wheel has a speed of 2·85 miles per minute, or nearly three times the speed of the "Flying Dutchman." This fly-wheel works on the main shaft from which the tube mill is driven by means of helical-toothed steel wheels.

The tubes are heated in a Siemens regenerative furnace, heated by radiation, which is distinguished by its great size; it is 33ft. long by 21ft. wide, and has an area of 789 square feet.

It is one of the many distinctive features of the Mannesmann process that much greater accuracy is required in the adjustment of the rolls than was hitherto dreamed of in the philosophy of iron and steel millwrights. Hitherto, even such delicate work as rolling fine wire rods, and thin sheets for tinning and stamping, has been accomplished by machinery, comparatively speaking, of the roughest description, in which the skill of the roller-man and roll turner had to make up for the inaccurate fitting and adjustment of the rolls. But in the Mannesmann mills every part is as carefully and accurately fitted as in a locomotive or marine engine, and the screws and balances are designed to, and do, enable the foreman roller to adjust the rolls to the 1-32nd of an inch.

After the tubes have been rolled, it is generally necessary to cut screws on the ends, as this is the usual way of connecting steel and wrought-iron tubes together, for making them into gas or water mains, and other similar purposes.

There are twelve screwing machines at Landore. They are made to cut screws on tubes of any diameter, from 2in. up to 12in. The screws cut by these machines are known as the American tapered thread screws. To work these machines, instead of cutting the screw to a uniform depth, we begin by making a deep cut, which slightly diminishes with every turn, so that the end of the tube becomes slightly conical. This is an improvement on the ordinary straight thread, as every turn makes the socket fit tighter on to the tube, while when it is wanted to unscrew the tube it is more easily released.

Comparative tables, giving the strength of Mannesmann and wrought-iron tubes were given, showing the former to be 50 per cent. stronger than the latter.

The tests under compression were made to show the value of the Mannesmann tubes for use in all sorts of engineering construction; even when the tubes are completely crumpled up they do not burst or crack.

What mainly distinguishes the tubes made by the Mannesmann process from all weldless tubes hitherto made is, first, that they are made from bars of solid steel or other metal into tubes without any preliminary boring of the material; and, secondly, that the fibre of the metal runs spirally round the tube when made. In all other processes for making weldless or seamless tubes the material is either cast in the form of a cylindrical ingot with a hole down its centre, or the metal, after having been cast, forged, or rolled into the form of a cylinder, has a hole bored through its centre. The hollow cylinder, whether cast or bored, is then drawn through a series of gradually diminishing dies, and over an appropriately-shaped mandrel, on a draw-bench similar to those employed in wire drawing. This, of course, necessitates frequent annealing of the material, as otherwise it would soon become brittle.

These successive drawings tend to produce a longitudinal fibre in the metal, just as the ordinary rolling of iron and steel bars and strips does, and such a longitudinal fibre necessarily tends to make the tube weaker, especially as regards internal pressure, than the Mannesmann tubes with a spiral fibre, the quality of the metal and all other conditions being the same in both tubes. That a spiral fibre has long been regarded as a source of strength is shown by the method adopted by gunsmiths for making shot guns of good quality. As is well known, these are made by welding together the best quality of scrap iron, such as horseshoe nails. These are carefully made into small rectangular rods, which are then coiled round a mandrel and welded together, and thus forming a spiral fibre. A collection showing this process in all its stages, from the packet of scrap iron to the finished gun barrel, is exhibited in the Museum of Practical Geology, Jermyn Street. On a large scale this process is used by Lord Armstrong for making the wrought-iron coils for his celebrated guns.

For purposes of comparison, two small bottles were made out of a Mannesmann tube and a lap-welded boiler tube respectively. These were filled with boiled water, and placed in a freezing mixture. The expansion which takes place on the solidification of water to ice exerted sufficient force to burst the lap-welded tube, but the Mannesmann tube withstands this great pressure. Another Mannesmann tube, 1in. in internal diameter, and about 3-64th of an inch in thickness, was subjected to an internal pressure of 3 tons 15 cwt. to the square inch, at Messrs. Siemens Brothers' telegraph works at Charlton, when the leather washer closing one of the ends gave way. When taken out the tube was distinctly warm to the touch, but otherwise exactly the same as before the test was applied. This pressure of 3 tons 15 cwt. per square inch is equal to a tensile strain on the metal of over 70 tons per square inch. The power of resisting great internal pressure makes the tubes particulary well adapted for vessels made to contain gases at high pressures, such as oxygen and carbonic acid, which are now being largely used in the arts, and it may also serve to extend the use of compressed air, a subject to which Sir Frederick Bramwell has devoted much attention.

The severest test which the Mannesmann tube can possibly be subjected to is the process of manufacture itself. If the metal is homogeneous throughout, and well melted, well rolled, and carefully heated, it makes, as you see, a perfect tube, or, at any rate, a near approach to it; but if there is any flaw in the bar, or if the furnace man has been careless in the heating, then the Mannesmann rolls reject that bar, by refusing to make a tube of it, more sternly than the severest human inspector would. This process is, in fact, so far as regards what is called humouring the metal, to the ordinary rolling process, what the tilt-hammer is to the late Mr. Nasmyth's steam hammer, so that every tube made by this process comes into the world ready tested.

As to the uses to which the tubes can be put, they can be used for all purposes for which tubes are now used; for water-pipes, especially where water has to be carried long distances at high pressure, they are already being largely applied. Further, their lightness and the greater lengths to which they can be made, will effect a large saving in the cost of labour in laying them down and in the cost of the joints, both of which form a serious item in the cost of any pipe line. What has been said of water applies equally to petroleum and to gas and steam. Another advantage of the Mannesmann tubes, for the purposes alluded to, is that they are capable of resisting much higher internal pressure in comparison to the thickness of their shells, or, in other words, of their weight per foot. While cast iron pipes will hardly stand more than 200lb. per square inch, and welded tubes are not as a rule safe above 1,000lb. per square inch, the Mannesmann easily withstand 2,000lb. per square inch. The length up to which these tubes can be easily made was shown by a coil made of a tube 3in. in internal diameter, and about a quarter of an inch thick, by 70ft. long; it weighs about 6½ cwt. Hollow axles for railway and other waggons, especially for field-gun carriages and ammunition and other waggons, hollow shafts and poles for carriages, can be readily made from these tubes, as well as gun barrels and gun tubes, and shells. The Prussian Government have already given the German Mannesmann works large orders for military stores of various kinds, or rather, for the tubes from which to make them; for instance, the lances with which the whole of the German cavalry are about to be armed are to be made of Mannesmann tubes, and are already in course of manufacture. Some of them were recently shown at Berlin, when Professor Reuleaux read a paper on the subject of the tubes before the Berlin Society of Engineers. Messrs. Reinhard and Max Mannesmann, the inventors of the process, are the sons of Mr. Reinhard Mannesmann, file and steel manufacturer in Remsheid, which has for centuries been, in conjunction with the neighbouring town of Solingen, what Sheffield and Birmingham are to England. More than thirty years ago Mr. Mannesmann, senior, tried to manufacture steel rifle barrels by rolling down carefully-cast hollow steel ingots, but did not succeed in getting sufficiently uniform results to proceed further than the experimental stage; but he never quite gave up the idea, and when his two eldest sons left the university he told them of his experiments. They took them up, and brought the training which they got at German universities, as well as their own indomitable perseverance, energy, and determination, to bear on this problem, and have, after years of hard work, succeeding in constructing the machines and devising the process. At present there are five works making, or about to make, tubes by this process. First, the parent works at Remsheid in Rhenish Prussia, where all the early experiments were carried out; then another works in South Germany, at Bous, near Saarbrücken; the Austrian works at Komotau; a works near Duisburg, which is being specially erected for making tubes of copper and its alloys; and, lastly, the works at Landore, near Swansea, belonging to the Mannesmann Tube Company, who have acquired Messrs. Mannesmann's English patent rights. At these works, which are under the management of Mr. Charles Mannesmann, a brother of the inventors, three Mannesmann mills are now at work, and two more are in course of erection, so that the works will soon be in a position to turn out large quantities of seamless steel tubes of all sizes from 1in. up to 16in. in diameter.

LIGHTNING CONDUCTORS FROM A MODERN POINT OF VIEW.

By Prof. Oliver J. Lodge.

A lightning conductor used to be regarded as a conduit or pipe for conveying electricity from a cloud to the ground. The idea was that a certain quantity of electricity had to get to the ground somehow; that if an easy channel were opened for it the journey could be taken quietly and safely, but that if obstruction were opposed to it violence and damage would result. This being the notion of what was required, a stout copper rod, a wide-branching and deep-reaching system of roots to disperse the charge as fast as the rod conveyed it down, and a supplement of sharp points at a good elevation to tempt the discharge into this attractive thoroughfare, were the natural guarantees of complete security for everything overshadowed by it. Carrying out the rain-water-pipe analogue, it was natural also to urge that all masses of metal about the building should be connected to the conductor, so as to be electrically drained to earth by it, and it was also natural to insist on very carefully executed joints, and on a system of testing resistance of conductor and "earth" so as to keep it as low as possible. If ever the resistance rose to 100 ohms it was to be considered dangerous.

The problem thus seemed an easy one, needing nothing but good workmanship and common sense to make accidents impossible. Accordingly, when, in spite of all precautions, accidents still occurred, when it was found that from the best-constructed conductors flashes were apt to spit off in a senseless manner to gun-barrels and bell ropes and wire fences and water butts, it was the custom to more or less ridicule and condemn either the proprietor of the conductor, or its erector, or both; and to hint that if only something different had been done—say, for instance, if glass insulators had not been used, or if the rod had not been stapled too tightly into the wall, or if the rope had not been made of stranded wires, or if copper had been used instead of iron, or if the finials had been more sharply pointed, or if the earth-plate had been more deeply buried, or if the rainfall had not been so small, or if the testing of the conductor for resistance had been more recent, or if the wall to which the rod was fixed had been kept wet, or &c., &c.,—then the damage would not have happened. Everyone of these excuses has been appealed to as an explanation of a failure; but because the easiest thing to abuse has always been the buried earth connection, that has come in for the most frequent blame, and has been held responsible for every accident not otherwise explicable.

All this is now changing or changed. Attention is now directed, not so much to the opposing charges in cloud and earth, but to the great store of energy in the strained dielectric between. It is recognised that all this volume of energy has somehow to be dissipated, and that to do it suddenly may be by no means the safest way. Given a store of chemical energy in an illicit nitro-glycerine factory, it could be dissipated in an instant by the blow of a hammer, but a sane person would prefer to cart it away piecemeal and set it on fire in a more leisurely and less impulsive manner. So also with the electrical energy beneath a thundercloud. A rod of copper an inch or a foot thick may be too heroic a method of dealing with it; for we must remember that an electric discharge, like the recoil of a spring or the swing of a pendulum, is very apt to overshoot itself, and is by no means likely to exhaust itself in a single swing. The hastily discharged cloud, at first, suppose, positive, over-discharges itself and becomes negative; this again discharges and over-discharges till it is positive as at first, and so on, with gradually diminishing amplitude of swing, all executed in an extraordinarily minute fraction of a second, but with a vigour and wave-producing energy which are astonishing. For these great electrical surgings, occurring in a medium endowed with the properties of the ether, are not limited to the rod or ostensible conduit; the disturbance spreads in all directions with the speed of light, and every conducting body in the neighbourhood, whether joined to the conductor or not, experiences induced electrical surgings to what may easily be a dangerous extent. For not only is there imminent danger of flashes spitting off from such bodies for no obvious reason—splashes which, on the drain-pipe theory, are absolutely incredible—flashes sometimes from a perfectly insulated, sometimes from a perfectly earthed, piece of metal; but, besides this, remember that near any considerable assemblage of modern dwellings there exists an extensive metallic ramification in the gas-pipes, that these are in places eminently fusible, and that the substance they contain is readily combustible.

On the drain-pipe theory, the gas-pipes, being perfectly earthed, would be regarded as entirely safe so long as they were able to convey the current flowing along them without melting; but, on the modern theory, gas-pipes constitute a widely spreading system of conductors able

Digitized by Google

to propagate disturbance underground to considerable distances, and very liable to have some weak and inflammable spot at places where they are crossed by bell wires or water-pipes or any other metallic ramification.

Above ground we have electrical waves transmitted by the ether, and exciting surgings throughout a neighbourhood by inductive resonance. Below ground we have electrical pulses conveyed along conductors, leaking to earth as they go, but retaining energy sufficient to ignite gas whenever conditions are favourable at considerable distances.

The problem of protection, therefore, ceases to be an easy one, and violent flashes are to be dreaded, no matter how good the conducting path open to them. In fact, the very ease of the conducting path, by prolonging the period of dissipation of energy, tends to assist the violence of the dangerous oscillations. The drain-pipe theory, and the practical aphorisms to which it has given rise, would serve well enough if lightning were a fairly long-continued current of millions of amperes urged by a few hundred volts, or if there were no such thing as electromagnetic inertia; but, seeing that the inverse proportion between amperes and volts better corresponds to fact, and seeing that the existence of electromagnetic inertia is emphasised by multitudes of familiar experiments, the drain-pipe theory breaks down hopelessly, and only a few of its aphorisms manage to survive it.

What, then, are we to set up in place of this shattered idol? First of all we can recognise, what was virtually suggested by Clerk Maxwell, that the inside of any given enclosure, such as a powder magazine or dynamite factory, can, if desired, be absolutely protected from internal sparking by enclosing it in a metallic cage or sheath, through which no conductor of any kind is allowed to pass without being thoroughly connected to it. The clear recognition of the exact, and not approximate, truth of this statement is a decided step in advance, and ought to be satisfactory to those who have to superintend the practical protection of places sufficiently dangerous or otherwise important to make the aiming at absolute security worth while. Similarly, for wire-covered ocean cables absolute protection is possible. But not for ordinary buildings, any more than for ordinary land telegraph offices, is such a plan likely to be adopted in its entirety. Some approximation to the cage system can be applied to ordinary buildings in the form of wires along all its prominent portions; and such a plan I have suggested, and I understand it is being carried out, for the entrance towers and part of the main body of the present Edinburgh Electrical Exhibition, Mr. A. R. Bennett having asked me to recommend a plan to the Committee as a sort of exhibit. For chimneys a set of four galvanised iron wires, joined by hoops at occasional intervals, and each provided with a fair earth, seems a satisfactory method; but it is to be noted that a column of hot air constitutes a surprisingly easy path, and that it is well to intercept a flash on its way down the gases of a chimney by a copper hoop or pair of hoops over its mouth. Mr. Goolden tells me that he has just applied this method to a new chimney at his works in the Harrow Road. For ordinary houses, a wire down each corner and along the gables is as much as can be expected. At many places even this will not be done; a couple of vertical wires from the highest chimney stacks on opposite sides must be held better than nothing or than only one.

Earths will be made, but probably they will be simple ones, entailing no great expense. A deep damp hole for each conductor, with the wire led into it and twisted round an old harrow or a load of coke, may be held sufficient. And as to terminals: rudely sharpened projections, as numerous as is liked, may be arranged along ridges and chimney stacks; but I have at present no great faith in the effective discharging power of a few points, and should not be disposed to urge any considerable expense in erecting or maintaining them. Crowns of points on chimneys and steeples are certainly desirable, to ward off, as far as they can, the chance of a discharge, but a multitude of rude iron ones will be more effective than a few highly sharpened platinum cones. I find that points do not discharge much till they begin to fizz and audibly spit; and when the tension is high enough for this, blunt and rough terminals are nearly as efficient as the finest needle points. The latter, indeed, begin to act at comparatively low potentials, but the amount of electricity they can get rid of at such potentials is surprisingly trivial, and of no moment whatever when dealing with a thundercloud.

But the main change I look for in the direction of cheapness and greater universality of protection is in the size and material of the conducting rod itself. No longer will it be thought necessary to use a great thick conductor of inappreciable resistance; it will be perceived that very moderate thickness suffices to prevent fusion by simple current strength, and that excessive conducting power is useless.

In the days when the laws of common "divided circuits" were supposed to govern these matters, the lightning rod had to be of highly conducting copper, and of such dimensions that no other path to earth could hope to compete against it. But now it is known that low resistance is no particular advantage: it is not a question of resistance. The path of a flash is a question of impedance, and the impedance of a conductor to these sudden rushes depends very little on cross-section and scarcely at all on material. A thin iron wire is nearly as good as a thick copper rod, and its extra resistance has actually an advantage in this respect, that it dissipates some of the energy, and tends to damp out the vibrations sooner. Owing to this cause a side flash from a thin iron wire is actually less likely to occur than from a stout copper rod.

The only limit is reached when the heat generated by the current fuses the wire, or runs the risk of fusing it. But in so far as oscillations are prevented, the mean square of current strength on which its heating power depends is diminished. Accordingly, a fairly thick iron wire runs no great risk of being melted. Its outer skin may, indeed, be considerably heated, for these sudden currents keep entirely to the outer skin, penetrating only a fraction of a millimetre into iron, and they make this skin intensely hot. But the central core keeps cool until conduction has time to act; and, consequently, unless the wire is so thin as to be bodily deflagrated by the discharge, its continuity is not likely to be interrupted. Thickness of wire is thus more needed in order to resist ordinary deterioration by chemical processes of the atmosphere than for any other reason.

But the liability to intense heating of the outer skin should not be forgotten, and care should be taken not to take the wire past readily inflammable substances for that reason. For instance, it would be madness to depend on Harris's notion that a lighting conductor through a barrel of gunpowder was perfectly safe, especially if said conductor were an iron wire or rod.

In the old days a lightning conductor of one or two hundred ohms resistance was considered dangerously obstructive, but the impedance really offered by the best conductor that ever was made to these sudden currents is much more like 1,000 ohms. A column of copper a foot thick may easily offer this obstruction, and the resistance of any reasonably good earth connection becomes negligible by comparison. A mere wire of copper or iron has an impedance not greatly more than a thick rod, and the difference between the impedance of copper and iron is not worth noticing.

But although, in respect of obstructing a flash, copper and iron and all other metals are on an approximate equality, it is far otherwise with their resistances, on which their powers of dissipating energy into heat depend. It is generally supposed that iron resists seven times more than copper of equal section, and so it does steady currents, but to these sudden flashes its resistance is often 100 times as great as copper, by reason of its magnetic properties. This statement is quite reconcilable with the previous statement, that in the matter of total obstruction there is very little to choose between them; the apparent paradox is explicable by the knowledge that rapidly varying currents are conveyed by the outer skin only of their conductor, and that the outer skin available in the case of magnetic metals is much thinner than in the case of non-magnetic.

Questions about shape of cross-section are rather barren. Thin tape is electrically better than round rod, but better than either is a bundle of detached and well-separated wires—for instance, a set of four, one down each cardinal point of a chimney; but it is easy to over-estimate the advantage of large surface as opposed to solid contents of a conductor. The problem is not a purely electrical one—it is rather mixed. The central portion or core of a solid rod is electrically neutral, but chemically and thermally and mechanically it may be very efficient. It confers permanence and strength; and the more electrically neutral it is, the less likely is it to be melted. Its skin may be gradually rusted and dissolved off, or it may be suddenly blistered off by a flash; but the tenacity of the cool and solid interior holds the thing together, and enables it to withstand many flashes more. Very thin ribbon or multiple wire, though electrically meritorious, is deficient in these commonplace advantages.

There were two functions attributed to high conducting power in the old days—first, the overpowering of all other paths to earth; second, the avoidance of destruction by heat. The first we have seen to be fallacious; on the second a few more explanations can be made. In so far as fusion by simple current strength is the thing dreaded, it must be noticed that a good conductor has no great advantage over a bad conductor. It is a thing known to junior classes that when a given current has to be conveyed less heat is developed in a good conductor, but that when an electromotive force is the given magnitude less heat is developed in a bad conductor. The lightning problem is neither of these, but it has quite as much relationship to the second as to the first. There is a given store of energy to be got rid of, and accordingly the heat ultimately generated is a fixed quantity. But the rise of temperature caused by that heat will be less in proportion as the production of it is slow; and though by sudden discharge a quantity of the energy can be made to take the radiant form, and spread itself a great distance before final conversion into heat, instead of concentrating itself on the conductor, yet this cannot be thought an advantage. For, just as in the old days a lightning rod was expected to protect the neighbourhood at its own expense by conveying the whole of a given charge to earth, so now it must be expected to concentrate energy as far as possible on itself, and reduce it to a quiet thermal form at once, instead of, by defect of resistance and over-violent radiation, insisting on every other metallic mass in its neighbourhood taking part in the dissipation of energy.

The fact that an iron wire, such as No. 5 or even No. 8 B.W.G., is electrically sufficient for all ordinary flashes, and that resistance is not a thing to be objected to, renders a reasonable amount of protection for a dwelling-house much cheaper than it was when a half-inch copper rod or tape was thought necessary.

A recognition of all the dangers to which a struck neighbourhood is liable doubtless prevents our feeling of confidence from being absolute in any simple system of dwelling-house protection; but at the same time an amount of protection superior to what has been in reality supplied in the past is attainable now at a far less outlay; while, for an expenditure comparable in amount to that at present bestowed, but quite otherwise distributed, a very adequate system of conductors can be erected.

Only one difficulty do I see. In coal-burning towns galvanised iron wire is, I fear, not very durable, and renewal expenditure is always unpleasant. It is quite possible that some alloy or coating able to avoid this objection will be forthcoming, now that inventors may know that the problem is a chemical one and that high conductivity is unnecessary.

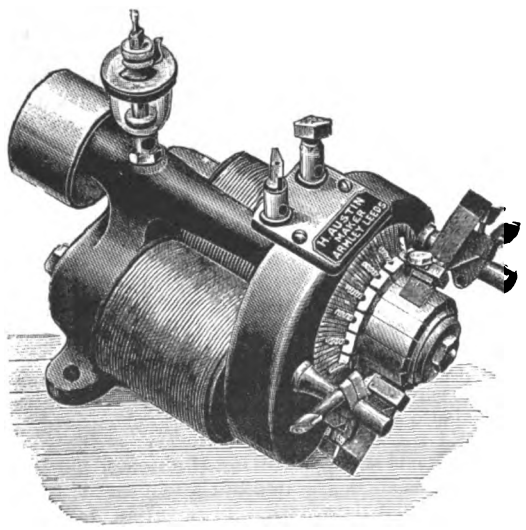
THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

(*From our New York Correspondent.*)

At the annual meeting of the American Institute of Electrical Engineers, held in New York, on the 20th of May, Professor W. A. Anthony, of Manchester, Conn., was elected president; Mr. Francis B. Crocker, Mr. Frank J. Sprague, and Mr. Joseph Wetzler, vice-presidents; Mr. J. C. Chamberlain, Mr. P. B. Delany, Mr. H. A. Foster, and Mr. H. Ward Leonard, managers; Mr. Geo. M. Phelps, treasurer; and Mr. R. W. Pope, secretary. The report of the council showed a gratifying increase in the membership of about 30 per cent., the total number of members being 427, and including electrical engineers of the highest standing. An arrangement has been entered into by which the Institute will hereafter have its headquarters at the house of the American Society of Mechanical Engineers, at 12, West Thirty-first Street, recently purchased.

After disposing of the business, a paper was read by Mr. Gilbert Wilkes, late of the United States Navy, on "Electricity in the Navy." The preference for power for electrical purposes in the navy is for simple double-acting high-speed engines. With a given plant, the engine should be constructed to allow little variation of speed under large changes of steam pressure, in order to take advantage of the main condenser when possible. Horizontal and vertical engines are both used, the preference being due in some cases to the shape of available space. Of late years all engines for electric lighting have been high speed, the largest about 25 h.p., running at 400 revolutions. The marine dynamo should be direct-driven and compact, free from liability to injury by salt water, and not too subject to mechanical damage. The dynamo should have small effect upon the compasses, a point which has received little attention. It should run easily and be non-sparking under constant load, and also able to stand sudden large changes of load with little sparking. This is necessary, as the incandescent dynamo is now used for the search light, and the conditions are aggravated by the fact that the latter is usually regulated by hand. Thus, with a 200 ampere machine, not only are 50 to 100 amperes thrown on or off, but at the moment the operator brings the carbons together the dynamo is suddenly called upon to deliver over three-fourths its total capacity. It should maintain a constant potential at all loads, which is accomplished by compounding, and as there is but about 3 per cent. drop it is usual to compound exactly or only over-compound enough to allow for decrease in engine speed with load. It should be light, and usually a careful study of the materials and arrangement of the

Digitized by Google



plant will accomplish more in reducing the total weight than a strict adherence to a specification of watts per pound of dynamo. No one dynamo can best fill all these conditions, and special cases arise demanding a rearrangement. On torpedo boats, for instance, high efficiency, low speed, and low heating, all give way to compactness and light weight. Experience with the Parsons turbo-electric generator demonstrated that it was so prodigal in the use of steam as to be out of the question for this service, and there is as yet no apparatus to satisfactorily fill this want. All American navy plants contain two or more similar sets, each composed of one engine and direct-driven dynamo. The standard pressure is 80 volts, having been fixed upon as the mean between the most efficient pressure for the incandescent system and the voltage necessary for the search lights. The incandescent lamps have always shown a satisfactory life, as they are used of low efficiency, 4 watts per c.p. being usually required. Search lights, of 50 volts and from 50 amperes upwards, are used, two or more being supplied, according to the size of the ship. The two-wire system has always been used, the ship never being allowed to form the return. Motors have been used only in driving fans up to ½ h.p. for hoists, and in one case for training a large gun on the "Chicago." There are numerous engines about a ship varying from 1 to 50 h.p., some of which might be replaced with advantage by motors, but it must be proved in each case that the motor not only does its duty as well as the engine, but also that it, and any attendant increase in the generating plant, is of less bulk and weight than the engine and piping. All circuits are waterproof, the cut-outs having stuffing boxes through which the lead-covered wires enter. Electric welding presents many advantages on board ship, especially at foreign stations. The man-of-war is a proper field for nearly every form of electrical application, while a navy yard is an ideal place for the erection of a central station for light and power. Good use is already being made of small motors for drilling purposes at the New York Navy Yard, where several are in constant operation, having driven out the portable steam engine, countershafting, and belting.

At the adjournment of the meeting those who intended taking part in the exercises of the 21st proceeded to Boston, Massachusetts, by the midnight train, a distance of 225 miles. The general meeting in Boston was called to order at 10 a.m. at the Massachusetts Institute of Technology, where an address of welcome was delivered by President Walker, and responded to on behalf of the electrical engineers by Past-President Elihu Thomson.

(To be continued.)

THE "INFANT" DYNAMO.

These machines are made in the small sizes, which most dynamo manufacturers find to be more troublesome than remunerative—viz., from 1,000 watts down to 100 and even 50 watts. The magnets are of annealed Swedish iron, screwed into the pole-pieces by a very fine thread, the idea being that a better contact is thus secured. The yokes have a sectional area thrice that of the magnet bars. The armature is made of No. 18 char-

coal sheet, the burrs being ground off and both sides insulated with a mixture of shellac and plaster of Paris. The armature, as shown in the illustration, is overhung, and can be easily taken out for examination. We have no information as to their performance. Good workmanship is of more importance in these small sizes than refinement of design, since it is impossible for several reasons to attain any tolerable electrical efficiency. These dynamos are made by Mr. H. Austin, 71, Amberley Road, Armley, near Leeds.

THE SOCIETY OF CHEMICAL INDUSTRY.

GLASGOW AND SCOTTISH SECTION.

At a meeting held at Glasgow, on the 3rd inst., Dr. Clark read a paper by himself and Mr. McGhie on "Transvaalite; a New Cobalt Mineral." This mineral was obtained from a mine situated about thirty miles north of Middleburg, in the Transvaal, and Mr. McGhie, having occasion in 1889 to be in that country, paid a visit to the mine, and brought home several samples, which were shown. The ore, which consists essentially of arseniate of cobalt, occurs in a vein of quartzite, and was worked for several years, after which it was abandoned, owing probably to the cost of transit and the difficulty of separating the ore from its matrix. The authors think, however, that if there were only a sufficient quantity of the mineral it would pay to export it to this country.

Mr. H. Ballantine read a paper by himself and Mr. R. T. Thomson, on "The Revision of Some Constants in the Analysis of Oils and Fats," and exhibited a table showing the specific gravity and iodine absorption per cent., which, as Dr. Clark said, would prove serviceable to public analysts, whose difficulty was to know what were genuine samples of oils and what were not.

Dr. G. G. Henderson also contributed a note on "The Purification of Artificial Salicylic Acid."

Notes.

CHEMICALS AT GENOA.

A Foreign Office report states that the imports of chemicals at Genoa have increased somewhat, and a new trade of considerable importance to us has sprung up in sulphate of copper, which is being largely used as a remedy for the vine disease. A little is made in the Alps, but most comes from Swansea. The demand is likely to increase.

MINING IN CHINA.

T'ang Chiung, ex-Governor of Yünnan, has forwarded to Pekin from Yünnan about 300 tons of copper. Mining has, however, been carried on there under difficulties, the ventilation being bad and floods occurring, while there is a want of transport, and copper has been stolen. He, however, expects better results in the future. About 1 cwt of copper is obtained from 1 ton of ore. At Ch'ingk'i, in Eastern Kueichon, machinery has been imported from Europe to smelt iron, but the works got flooded, and delay has thus been caused. Indications of copper have been found here.

DRY GOODS IN MADEIRA.

The old complaint of British Consuls as to neglected opportunities on the part of British manufacturers again crops up. This time it comes from Consul Keene, of Madeira, who asserts that the importation of dry goods is considerable, and carried on almost entirely by foreign countries other than England, the reason being that our makers send few or no commercial travellers out. "English houses applying to the Consul for information cannot cope with the foreign traveller who deals directly and on the spot with local firms and shopkeepers, and who gives long credit."

TELEGRAPHIC MESSAGES FOR ATLANTIC STEAMERS.

Arrangements are being made for carrying out a scheme proposed by Mr. McNeil, of Londonderry, for the more efficient despatch of telegraphic communication between Tory Island and the mainland, which promise to be of great advantage to shipowners and homeward-bound passengers. It is proposed that steamers passing on either side of Tory Island will throw overboard receptacles something like a small buoy, containing the messages to be sent by telegraph, and a boat's crew will be in readiness to pick them up and convey them to the nearest telegraph office. By this means it will be possible for a passenger to intimate his arrival to his friends twenty-four hours before he could do so now from Liverpool, and twenty hours before he could do so from any port on the Clyde. The matter has been taken up by Lloyd's Committee, who undertake to forward passengers' telegrams at a minimum of 1s. each, and shipowners' advices at a minimum of 6d. each. It is expected that the arrangements will be carried out by the end of August next.

TEXTILES IN CHINA.

At Ichang last year there was a general fall in the imports. Cottons amounted to £268,949, a decrease of £15,199 compared with the previous year, but cotton yarn advanced. The latter was due to the failure of the cotton crop in the province. Woollens have fallen heavily, the greatest decreases being in lastings and Russian cloth. Italian cloth (made in England), however, is rapidly extending its market. Silk piece goods from Hangchow, and ribbons from Canton, have increased. A large quantity of the imports at Ichang are merely in transit to the South-Western provinces.

SPRAGUE'S ELECTRIC CAR MOTORS.

A short paper on the Sprague motor was read by Mr. H. F. Parshall before the American Institute of Electrical Engineers on the 21st of May. The paper deals only with the magnets and their dimensions and magnetisation. The pole-pieces are slightly bell-mouthed or chamfered, and their horns are cut away on each side with the view of lessening sparking and allowing the brushes to be shifted. The shape of the pole-pieces cannot, however, be considered without reference to the construction of the armature, of which no details are given. The reason for the bell-mouthing is not clear, and the cutting away of the horns laterally seems to offer no advantage over the not uncommon practice of increasing the air space towards the tips, by several well-known methods, for the purpose, not of lessening sparking, but of reducing local heating. Curves are given showing the effect of cast-iron side brackets, which appear to reduce the total induction from 2,600,000 to 2,550,000, with the usual excitation of 14,000 ampere turns. Another curve, with an air gap of 2·85 centimetres instead of 3·2, shows the difference between cast-iron and wrought-iron pole-pieces. At the above induction the cast iron gives 2,800,000 and wrought iron 3,100,000, a difference which might easily be eliminated by a proper design of the cast-iron pole-pieces.

THE COTTON INDUSTRY.

Spinners continue to declare fairly satisfactory profits, though the margin is still poor. The results, however, are explained by spinners having in stock moderately large supplies of the raw material which were purchased some months ago. The following results for the past three months are announced :—

Mill.	Spindles.	Profit.
North Moor	80,000	£1,460
Woodstock	82,000	1,027
Shiloh.....	37,000	723
Lansdowne	52,000	750
Commercial	62,000	454
Star.....	103,400	2,025
Duchess	72,000	1,248
Central	60,000	777
Gladstone	86,000	856
Arkwright	76,000	2,155
Crawford	154,000	3,300

The margin at the present time is little more than change for a shilling. Those spinners who are not bought to the end of the season are rather concerned at the high prices now ruling for raw American cotton. Already spinners are looking forward anxiously for the new crop, latest telegrams being on the whole encouraging. It is satisfactory to report a large crop of East Indian cotton this season, the figures so far showing an increase of 300,000 bales on last year. Cloth is strong in the leading staples, owing to the unusually deep engagements of makers. India shippers have recently bought largely, some say speculatively. As in yarn, however, the margin is poor. The latest telegraphic news from India respecting the monsoon rains is satisfactory. The weavers' wages list is likely to be settled without resort to a strike. Our total shipments of cotton goods and cotton yarns for the month of May last are encouraging, the figures in each case being larger than the corresponding month in 1889 and 1888, as shown by the following table :—

	Yarn. May.	Five Months ending May 31.
1890	24,135,900 lb. ...	110,804,000 lb.
1889	21,638,500 „ ...	108,887,100 „
1888	21,874,900 „ ...	107,743,000 „
	Cloth.	
1890	470,574,400 yards	2,099,100,600 yards
1889	429,838,000 „ ...	2,158,835,500 „
1888	430,580,300 „ ...	2,077,348,300 „

Patent Record.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

27th May, 1890.

8181. Pennycook, J. T. ..... Pneumatic signalling apparatus.
8192. Sherwin, G. E. ..... Heating, purifying, cooling, distilling, and evaporating water.
8194. Sinnette, F. J. ..... Stockless anchor.
8200. Leinweber, H. ..... Magazine firearms.
8205. McConnell, R. ..... Winding yarn.
8209. Townson, T. ..... Slide valves.
8211. Walker & Greenwood Looms.
8220. Newman, N. ..... Car couplings.
8221. Tuquet, Boudard, & Crawley ..... Double action jacquard.
8223. Bunnett, Fache, & Nicholls ..... Magazine firearms.
8225. Bromhead, S. S. ..... Paper box machines (*Knight & Knight*).
8229. Lake, W. R. ..... Welding metal rings (*Lemp*).
8230. Elliot, H. C. ..... Cigarette machines.
8231. Kohler, E. ..... Sewing machines.
8244. Lake, W. R. ..... Magazine firearms (*Winchester Repeating Arms Company*).
8245. Scott, J. ..... Metal dies.
8247. Finckenstadt & Roy ... Compensator for ships' cables.
8251. Redfern, G. F. ..... Apparatus for scouring and wiping tinned sheet iron (*Seutter*).
8252. Henrici, W. A. E. ..... Ironing machines.
8255. Mills, C. K. ..... Keeping ordnance cool during firing (*Gathmann*).
8258. Varilla, P. B. ..... Railway communication between lands separated by water. (23rd May, 1890.)
8265. Livingstone & Cooper... Metallic fences.
8267. Allaire, Gautier, & Poulard ..... Helicoidal propeller.

28th May, 1890.

8270. Sutcliffe & Sutcliffe Apparatus for treating textile materials.
8271. Burns, D. ..... Mowers and reapers.
8275. Moss, J. ..... Boiler furnaces.
8280. Potter, R. P. ..... Metal tanks, &c.
8283. Jones & Bridger ..... Apparatus for forming boots and shoes.
8290. Mills, T. ..... Propelling vessels.
8291. Nixon & Millichamp ... Recording dynamometers.
8295. Versen, B. ..... Linings for converters.
8299. Forbery, G. V. ..... Breechloading firearms.
8301. Huelsen, C. ..... Brick presses (*Welger*).

29th May, 1890.

8309. Silbereisen, J. ..... Wells and other borings.
8312. Patterson & Gray ..... Pump.
8314. Griffiths, T. ..... Ventilation of collieries.
8319. Jopling, J. C. ..... Combustion of smoke.
8321. Stratton & Perry ..... Machinery for making barbed wire goods.
8322. Popp, V. ..... Compressed air motors.
8326. Jones, G. ..... Brakes.
8328. McKee, T. A. ..... Rotary engines.
8329. Pollard, A. W. ..... Calculating machine.
8334. Baillie, R. A. ..... Upsetting metal bars.
8341. Goltz, H. F. C. ..... Pneumatic brakes.
8342. Bentall, E. H. ..... Harvesting machines.
8343. Nightingale, W. W. ... Lifts.
8344. Shoosmith, H. ..... Punch-drawing machinery.
8346. Faure, P. P. ..... Decorticating machines.
8352. McDermott, W. ..... Apparatus for separating ores.
8353. Lake, W. R. ..... Apparatus for elevating straw (*Cyclone Manufacturing Company*).
8356. Chamberlain & Silbereisen ..... Composite pinions and gear wheels. (21st January, 1890.)

30th May, 1890.

8359. Hall, S. ..... Governing mules.
8360. Paterson, G. ..... Increasing power of wheels.
8366. Poole, W. H. ..... Metallic packings.
8367. Hoyle, W. H. ..... Knitting machinery.
8369. Popp, V. ..... Compressed air systems.
8380. Wilson, Cook, & Winter Tramway rail joints.
8382. Morrison & Harper..... Steam engines, &c.
8384. Lister & Watts ..... Grinding mills.
8385. Kerby, H. ..... Plough for draining land.
8387. Leach & Sinkinson ..... Machinery for taking threads out of laps.
8389. Remy, Kramer, & Herking ..... Colouring matters.
8395. Krais, A. K. J. ..... Purifying feed water.
8397. Gillson, S. ..... Liquid meters.
8399. Aitken, H. ..... Iron.
8406. Henniker, Bedingfeld, & Jones ..... Breechloading small arms.
8409. Wells, H. ..... Brakes.
8415. Meltzer, H. F. G. ..... Steam engines.
8418. Barnes, S. K. ..... Boiler furnaces
8419. Roegel & Von Neubronn Slitters and cutters for paper machinery.
8422. Evenstad & Senstad ... Manufacture of wood wool.
8424. Hillas, I. ..... Double lift open shed jacquard.

31st May, 1890.

8426. Neate, P. J. ..... Rotary sieves.
8429. Hurtley, J. ..... Warp balling machines.
8431. Seage & Seage ..... Gas engines.
8432. Paget, A. ..... Warp-weaving machines.
8434. Bayly, J. P. ..... Cylinder paper machines (*McNamar*).
8436. Bayly, J. P. ..... Horizontal telescopic press (*Diffey*).
8441. Harbord, J. M. ..... Railway chairs.
8443. Fielden, E. ..... Loom brake.
8448. Wilson & Pirrie ..... Steam steering gear.
8450. Ingham & Moorhouse ... Twisting machines.
8458. Walden, A. ..... Ploughs.
8463. Shepherd, J. C. ..... Axles.
8466. Cole, O. K. ..... Governor. (11th December, 1889.)
8475. Lawson, Lawson, & Dear Machines for preparing flax, &c.
8480. Childs, B. ..... Axles.
8483. Griffin, H. R. ..... Mowing machines (*Walter A. Wood Mowing and Reaping Machine Company*).

ELECTRICITY.

27th May, 1890.

8241. Jeffers, C. L. ..... Electric lamp hangers.
8242. Lake, W. R. ..... Electric welding (*Lemp*).
8253. Krieger, Stitzel, Weinedel, Schwartz, Reutlinger, & Egelhoff ..... Electric semaphores.
8254. Haddan, R. ..... Accumulators (*Pescetto*).

28th May, 1890.

8272. Wilkins, S. B. ..... Electrical fire or burglar alarms.
8286. Todman, J. T. ..... Electrical cut-outs.

29th May, 1890.

8306. Lake, H. H. ..... Electric relays (*Law*).
8325. Poncia, J. M. A. ..... Preventing injuries to submarine cables (*Kingsford*).

30th May, 1890.

8362. Dummer, E. ..... Electric locomotives.
8379. Thompson, W. ..... Connecting the telephone with the phonograph and telegraph.
8392. Thompson, W. P. ..... Conduits for electric cables (*Jacob Frères et Cie.*).
8393. Drake, Gorham, & Pringle ..... Switches.
8394. Wright, W. ..... Battery compound.

31st May, 1890.

8427. Apps, A. ..... Electric arc lighting.
8442. Forbes, Sir C. S. ..... Primary batteries.
8469. The Mining and General Electric Lamp Company, Ld., & Fitzgerald ..... Battery elements.
8471. Morgan, E. H. ..... Electric locomotives.
8474. McEvoy, C. A. ..... Switches.
8477. Beevor, S. F. ..... Switches.

CHEMISTRY.

27th May, 1890.

8215. Hall, J. ..... Colouring matters.
8233. Dowden, W. A. A. ..... Extraction of gold.
8239. West, W. S. ..... Treating sewage.
8243. Lake, W. R. ..... Colouring matters (*Leonhardt & Co.*).
8262. Sullivan, Sir E. R. ..... Manures.

28th May, 1890.

8294. Lagoutte & De Velna... Solidifying mineral oils.
8303. Johnson, J. Y. ..... Alizarine blue (*Badische Anilin & Soda Fabrik*).

29th May, 1890.

8324. Weathered & Morgans Recovering mercury and amalgam.
8332. Greenway, A. G. ..... Treatment of galvanisers' waste acids.
8357. Cowper-Coles, S. O. ..... Coating with tin.

30th May, 1890.

8364. Waddle, M. R. ..... Cleaning tinplates.
8373. Walker, E. W. ..... Manufacture of gas.
8411. Willcox, B. ..... Colouring matters (*Farbenfabriken vormals Friedrich Bayer & Co.*).

31st May, 1890.

8454. Williams & Symons..... Calcium phosphate.
8470. Koenig, J. B. ..... Soap.
8484. Hogg & Lorrain ..... Purifying oils.

MISCELLANEOUS.

27th May, 1890.

8197. Johnson, J. Y. ..... Graphophones (*Edison United Phonograph Company*).
8202. Thompson, W. P. ..... Pantographs (*Dammann*).
8238. Bell, J. ..... Dyeing and finishing goods.

29th May, 1890.

8339. Hook, C. ..... Anti-fouling compound for steam boilers.

30th May, 1890.

8413. Hartnell, J. ..... Artificial stone.

31st May, 1890.

8451. Longair, D. ..... Measuring liquids.
8452. Knecht, E. ..... Separation of textile fibres.
8455. Major, H. J. ..... Screws.
8464. Mills, L. ..... Spanners.
8481. Ward & Gregory ..... Priming and detonating composition.

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given, give notice at the Patent Office, in the prescribed form of such opposition.

Year 1889.

6882. Thomas Crisp Sanderson.
8734. Boyle & May.
9301. Gill.
9578. King (*Roberts*).

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

PETROLEUM, &c., ENGINES.—*J. C. Bull, Belvedere.*—At present engines worked by exploding a mixture of air and combustible vapour work more advantageously with the lighter and more volatile oils. To enable the use of the heavier oils the inventor vaporises them in a closed vessel at a temperature of about the boiling point of water. The vaporising vessel is enclosed in a boiler and surrounded by water. If the temperature of the oil has to be raised above that of the boiling point of water chloride of calcium is added to raise its boiling point. Any excess of petroleum vapours is permitted to escape by a loaded valve from the vaporising vessel to a condensing reservoir, a similar precaution being also taken with respect to the steam developed in the boiler. The condensed vapour and steam can be repassed to the vaporising vessel and boiler at will. The engine is constructed to draw its supply of vapour from the vaporiser, and to admix the vapour with air or just before it enters the cylinder of the engine to be exploded. To make the apparatus perfectly safe the receiver for condensed petroleum is made of sufficient capacity to hold all the contents of the vaporiser and the receiver for condensed steam to hold all the contents of the boiler. Five claims are made.—No. 10634. July 1st, 1889. 8*d.*

PISTONS.—*J. Drury, Brighouse, Yorkshire.*—This describes an inproved packing ring for pistons and means for lubricating it. The new form of ring is illustrated in Fig. 2. The inner faces are bevelled and pressed outwards by a coiled spring. In Fig. 1 is shown the method of lubricating the rings in a vertical engine. To the piston A is screwed a tube B, whose interior communicates by an aperture with grooves cut in the piston rings. The tube extends through the cylinder cover C into a tubular chamber D nearly filled with lubricating oil. The tube partakes of the up and down motion of the piston, and is consequently kept full of oil, which flows to the piston rings. Three claims are made.—No. 8584. May 23rd, 1889. 8*d.*

FIG. 1

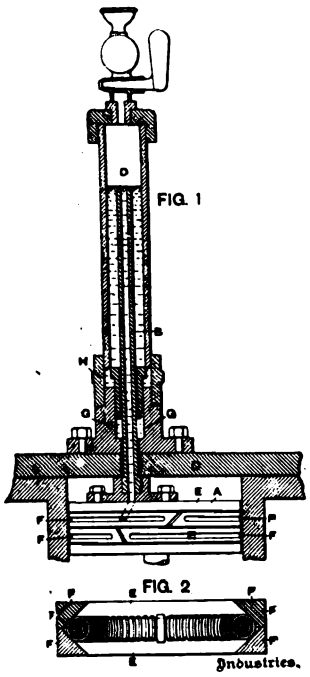

FIG. 2

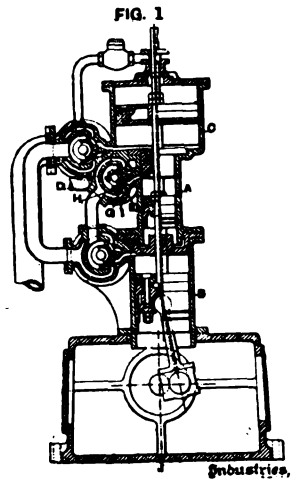
ROLLED FORGINGS.—*R. C. Christie, London.*—The invention refers to the dies employed in forging screw-threads by rolling. The method of forging is as usual, one or both of the dies being made to move across the face of the other and roll the blank metal into the depressions in the dies corresponding to the screw-threads. By the construction of some old forms of dies, the metal displaced to form the thread is raised radially from the blank, so that the diameter of the finished screw is greater than that of the blank. In another class of dies, the metal displaced is made to elongate the blank; the thread is here formed by a single ridge. Both of these methods tend to distort the thread. By the improved die here described the metal is displaced longitudinally, but the thread is formed by a series of parallel ridges. The ridge nearest the shoulder is arranged to act upon the blank first, and after a complete turn has been formed the next ridge of the series commences to operate, and so on. Ten claims are made.—No. 10453. June 27th, 1889. 8*d.*

CENTRIFUGAL DRUMS FOR SEPARATING MILK.—*S. C. Hauberg, Copenhagen, Denmark.*—The inventor claims the following advantages in the drum described. Greater cheapness of manufacture; more facility for cleaning; increased strength; and better separating power. To increase the strength and facilitate the cleaning of drum, it is made of a globular shape of approximately the same thickness throughout. The bottom of the vessel does not partake of the globular form, but is bent upwards and inwards to form a cone similar to that of a glass bottle. The increase in separating power is caused by increase of speed and the peculiar construction of the wings in the interior of the drum. The milk is passed in at the top of the vessel, and flows down to the bottom. As the milk is exposed to the centrifugal force, the fatty particles separate and move to the centre. By the construction of the wings, the milk, as it is introduced, is kept from disturbing the separating action taking place in that first introduced. Four claims are made.—No. 13981. September 5th, 1889. 8*d.*

STEAM ENGINES.—*W. R. Renshaw, Kidsgrove, Staffordshire.*—The illustrations show this improved form of triple-expansion engine, Fig. 1 being a sectional side elevation, Fig. 2 a front elevation, and Figs. 3 and 4 the valve connections. There are two sets of cylinders, with three cylinders A B C and A^1 B^1 C^1 in each set. The cylinders are single acting, their pistons are connected to one piston rod, and one connecting rod couples them to the crank-shaft. The cranks of the crank-shafts are diametrically opposite. The high-pressure cylinder A first receives the steam on the upper side of its piston, and at the end of the stroke this steam passes to the intermediate cylinder B^1 of the other set; the piston of B^1 thus makes its effectual down-stroke as the high-pressure piston ascends. From B^1 at the end of its stroke the steam passes to the lower pressure C^1, and there acts upon the underside of the piston. The steam is admitted from the steam pipe D to the high-pressure cylinders by a cylindrical valve E. The axis of the valve is horizontal, and the valve receives a partial rotary motion to and fro by an eccentric F. The valve is open at the back and the steam pressure is constantly upon it. A port G in the valve allows steam to pass alternately to the high-pressure cylinders A A^1. There is a cavity H formed in the valve on either side of the steam port, and this cavity in the to and fro motion of the valve forms a communication between the steam passage leading to the cylinder and the exhaust or outlet passage I. At each movement of the valve the steam port in it passes from the passage leading to the one high-pressure cylinder to that leading to the other high-pressure cylinder, and during the same motion the cylinder which at first is supplied with steam is opened to the exhaust as the valve approaches the end of its course. The admission of the steam to the high-pressure cylinders is further regulated by a cut-off valve J, which fits into a concentric cylindrical cavity formed in the main valve E. This cut-off valve is so formed at the periphery that its acting portion consists only of two bars parallel to the axis of the valve and to the steam port. The cut-off valve is independently rotated through a constant angle first in one direction and then in the other by an auxiliary eccentric K. By this means one or other of the bars is brought to cover the steam port in the main valve at the time when the cut-off is required to take place. The anxiliary eccentric K is controlled by a governor which alters the lead of the eccentric so that when the speed increases the auxiliary valve cuts off the steam earlier. The valves of the intermediate and low-pressure cylinders are constructed similarly to the high-pressure valve. The governor is enclosed in the hollow fly-wheel L, and consists of two weights having a radial motion by which the eccentric K is shifted upon the crank-shaft. When the speed of the engine increases or decreases, the weights move outwards or inwards, and the eccentric is turned in one or the other direction upon the shaft. Claims: (1) A triple-expansion engine with two sets of three cylinders, each set having a common piston rod; (2) a triple-expansion engine with three single acting cylinders whose pistons have a common rod and valves so arranged that steam is admitted to the same end of the two higher pressure cylinders and to the other end of the lowest pressure cylinder as described; (3) a triple-expansion engine, with two sets of three cylinders, each set having a common piston rod and valves such that steam is first admitted to one end of the high-pressure cylinder of one set, then to the same end of the intermediate pressure cylinder of the other set, and lastly to the other end of the low-pressure cylinder of the last-mentioned set, as described; (4) in engines such as are referred to in claims 1 and 3 admitting and exhausting steam to and from the cylinders by means of three valves, one for each pair of similar cylinders, substantially as described; (5) the valves and gear for working the same, substantially as described; (6) the pistons, substantially as described; (7) engines, substantially as described and illustrated.—No. 9771. June 13th, 1889. 11*d.*

FIG. 1



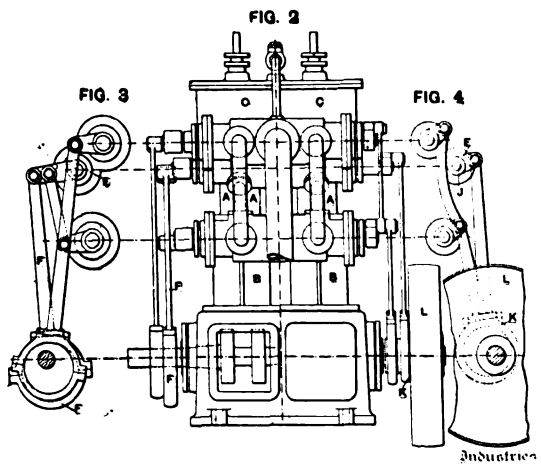


FIG. 2

FIG. 3

FIG. 4

STEAMBOATS AND OTHER VESSELS.—*W. P. Thompson, Liverpool.* (*F. W. Pool, St. Paul, U.S.A.*)—The vessel is double-prowed to enable it to be propelled in either direction. Both ends are fitted with a rudder, and the rudders are made to act in concert, so that the vessel can be turned in more limited space than by the use of a single rudder. The rudders are geared together by mitre wheels and shafts, which extend the length of the vessel, and are geared to the steering wheel. The vessel is propelled by pistons working in cylinders, which have open ends, and are situated at the ends of the vessel with their axes longitudinal. Only one piston is geared at a time to the motive power, that one which is for the time at the stern of the vessel. Water is drawn into and expelled from this cylinder through the open end by the reciprocating piston, and, as it is expelled, forces the vessel forward. Seven claims are made.—No. 9386. June 6th, 1889. 8*d.*

CLEANING MALT, &c.—*R. A. Baumgartner, Rosenheim, Germany.*—The improved machine is built upright, and consists of the following principal parts:—A suction ventilator B; a separator C, with air regulation; a compartment D, in which the material is freed from sprouts; a compartment E, for removing sprouts and husks from the material; and a polishing chamber F. All movable parts of the apparatus are operated from a vertical shaft A. The ventilator B passes the sprouts, husks, and dust immediately into the dust chamber. The separator C consists of two cylinders, telescopically displaceable one within the other, the upper one being raised and lowered by a lever G. This arrangement permits the regulation of the outer current of air between the perforated mantle H and the dust mantle I, so that radicles or other waste matter may be expelled separately. The malt to be cleaned is passed in at J to the first cleaning drum. The inlet so regulates the supply of material as to cause the interstice between the drum and mantle H to be entirely filled up. The drum is revolved at a high speed, and by the open friction and driving wings K the grains are pressed and rubbed without injury against each other and the mantle. The coarser sprouts and waste substance are expelled through the perforations of the outer mantle, and either fall down or are driven up by the current of air regulated by the adjustable cylinders C. The finer waste particles are expelled through the inner covering by the suction current. The operation in the second compartment, into which the material freed from sprouts descends through the apertures L, is the same as in the first chamber. The husks, dust, particles, &c., removed from the material are likewise eliminated by the suction current. Any residue of impurity adhering to the grains is eliminated through the polishing chamber F. The china segments M rub off the husks and fibres, these finer waste matters being removed by suction through interstices, covered with finely perforated sheet metal, as well as through the outer mantle, allowing the malt to leave the machine through the outlet O in a perfectly cleaned and polished condition. Claim: An apparatus for cleaning or polishing malt or grain, in which the material is first worked by horizontally rotating perforated drums, provided with open fans or wings K; then, by means of a polishing drum, consisting of china segments M, with intervening perforated sheet steel pieces N and wings P, provided alternately above and below, in single superposed cylinders H, separated from each other by diaphragms, and covered with correspondingly perforated metal sheets, while a current of air, adjustable by means of displaceable tubes C provided in the so-called separator, passes through the drums of the different storeys outside between the cylinder mantle H and mantle I, and also inside the sides of the drums, thereby expelling the light and heavy waste matter separately, substantially as and for the purpose set forth.—No. 8427. May 21st, 1889. 8*d.*

FIG. 1

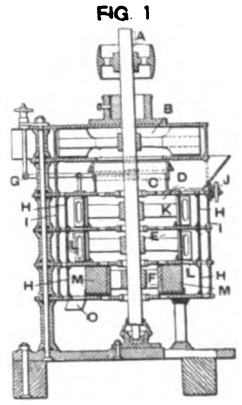

FIG. 2

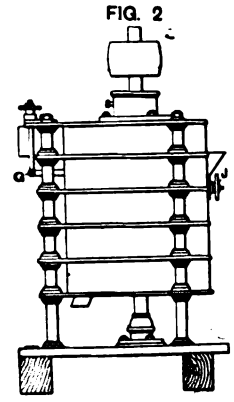

FIG. 3

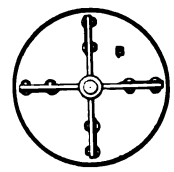

FIG. 4

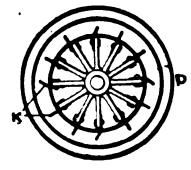

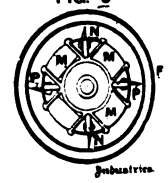

FIG. 5

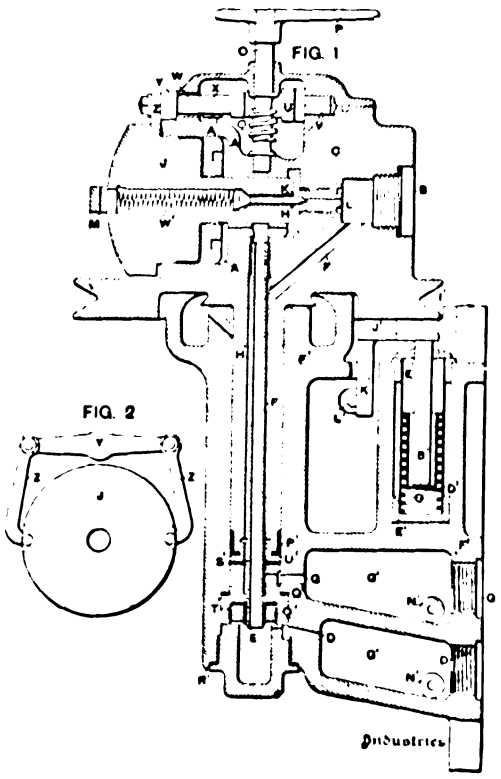
BOILER FURNACES.—*E. Prime, Barrington, & W. Lee, Melbourne, Cambridgeshire.*—This invention relates to a method of more completely consuming fuel in furnaces. For this purpose heated air is introduced at the back of the bridge to mix with the inflammable gases and form combustion. The bridge of the furnace is made hollow, and open at the top, with a deflecting hood which directs the heated air from the chamber towards the flue. The air is supplied to the chamber in the bridge by a pipe leading from the front of the boiler, the inlet end of this pipe being made conical to enable a larger quantity to be drawn in, or made of a number of funnels concentrically arranged. For locomotive furnaces, the air chamber can be either fitted in the smoke-box or around it, with suitable division so that the current of air may receive a backward and forward movement, and become heated before entering the tube leading to the fire-box. Five claims are made.—No. 9758. June 13th, 1889. 11*d.*

Digitized by Google

APPARATUS FOR CONTROLLING PRESSURE, &c.—*J. I. Thornycroft, Chiswick.*—This apparatus, besides controlling the pressure in a receptacle, may be made to indicate by pressure the speed at which a body, such as a shaft, rotates when that body is suitably connected to it. It consists of a revolving part in which there are valves actuated by centrifugal force. This revolving part is rotated by the body whose speed has to be indicated. The valves are two in number, and control three passages, which communicate to an exhauster, to the atmosphere, and to the pipe or vessel in which the pressure is to be controlled. The pressure to be controlled is below that of the atmosphere. In the illustrations,

FIG. 1



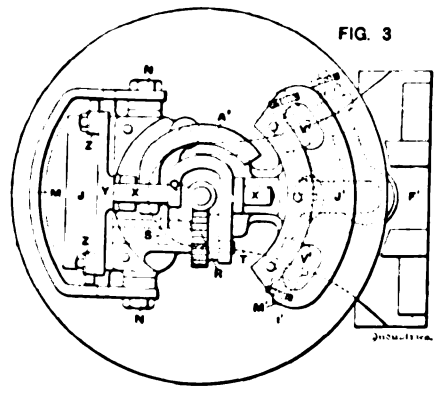


FIG. 2

Fig. 1 is a vertical section of the appliance, Fig. 2 a detail, and Fig. 3 a plan. The part C is revolved by a band passing around the pulley I¹ and the body whose speed is to be indicated. In the part C is a sliding circular plug J carrying the double valve with faces H and I. This valve closes the passage W¹ leading to the atmosphere and interrupts the communication between the exhauster G and the receptacle D in which the pressure has to be controlled. The pressure is controlled as follows: The tendency of the atmospheric pressure is to force in the plug J. If the speed of the revolving body exceeds the normal, this force is overcome by centrifugal action, and the valve is opened at H, so forming communication by the passages D, E, K, L, F, and G, between the exhauster G and the pressure chamber D, the pressure in D being thus reduced. If the speed of the body falls below the normal, then the valve will open at I and air from the atmosphere will flow in and increase the pressure in D. By suitably fitting the pressure chamber D with gauges the variation of pressure may be made to indicate the speed. To facilitate the motion of the plug J and prevent it sticking, it is made to reciprocally rotate about its axis by the rocking lever Y connected to the plug as shown in Fig. 2. The rocking lever is supported upon a spindle X, which carries a slotted lever U. A pin in a worm-wheel R works in the slot of the lever U and imparts to it a vertical reciprocating motion as the worm-wheel is revolved. A fixed worm Q gives the worm-wheel its motion

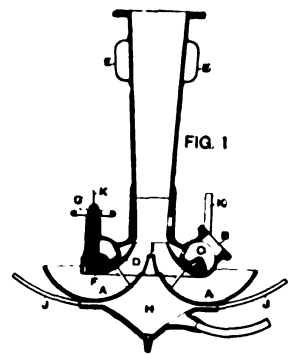
FIG. 3

as it revolves with the part C about a vertical axis. For indicating the direction of rotation a lever J¹ in frictional contact with the revolving part is constructed to partially rotate about the spindle B¹ and form electrical contact between the post K¹ and one of two stops L¹. The stops L¹ and the post are connected to an electric battery in which is placed the indicator. The posts L¹ are arranged to make the current pass in contrary directions the one to the other. Six claims are made.—No. 1077. January 21st, 1889. 8*d.*

IGNITING TUBES OF GAS ENGINES.—*H. Williams, Stockport.*—These tubes when made of iron, and subjected to the action of a very hot flame, soon oxidise, and become practically useless. The inventor has found, after a series of experiments, that the best material to make these tubes of is pure nickel. This metal gives good results, and is very durable. In making the tubes, a solid bar of nickel is bored out, so as to form a tube closed at one end, and having the required diameter and thickness of shell. Claim: An improved incandescent tube for firing the explosive charges of gas and other similar motor engines, said tube being constructed of nickel for the purposes specified.—No. 11162. July 11, 1889. 4*d.*

PETROLEUM ENGINES.—*J. M. Grob, O. Schultze, & A. Niemczik, Entritzsch-Leipzig, Germany.*—The improvements relate to the vaporising chamber of petroleum motors in which the chamber is in direct communication with the explosion chamber, so that the highly heated combustible gases may act directly on the vaporising surfaces. The motor of this invention is provided with two air inlets—one being as small as practicable, in order to avoid cooling, and serving wholly for the proper distribution of the petroleum to the vaporising surfaces; the other, and larger one, is made to supply the air required for combustion. In fitting the appliance to a vertical cylinder the cover of the cylinder is made hollow and of a conical internal shape. At the apex of the cone is the large air opening, having a valve with a motion in direct line with the axis of the piston. A spring tends to keep the valve closed against the pressure of air. On the side of the conical-shaped cover is fitted the appliance for admitting the petroleum vapour and its accompanying small supply of air. This appliance is of tubular form, and is placed horizontally, so that the petroleum vapour as it leaves the appliance enters the conical-shaped cover in a direction at right angles to the flow of the larger air supply. The valve of the petroleum supply is operated by the motion of the valve for the large supply of air. Thus, when the large air supply is opened the petroleum supply is also open. The pressure of the air supply is sufficient to open the large valve, but if there is any back pressure in the cylinder the extra pressure closes the valve. Claims: (1) In petroleum motors a double air inlet or two inlets, one serving solely for distributing the oil on the vaporising surfaces, and the other and larger one for the introduction of the air for combustion as described; (2) in petroleum engines the introduction of the air for combustion at right angles or nearly so to the entering gas jet in the manner that the gases of the same are enveloped without coming into contact with the cool surfaces.—No. 2919. February 24th, 1890. 6*d.*

BLAST ELEVATORS FOR GRAIN.—*F. W. Anchill, Northampton, & J. Walker, Ruchthuck, Bulgaria.*—The receiving part of blast elevators is here referred to, the improvements being the more effectual distribution of the blast and feeding of the hopper with grain. In the accompanying illustrations, Fig. 1 is a vertical section and Fig 2 a plan of the improved part. The part is embedded in the grain, which flows into the hopper A, and is carried up the elevator tube by a blast of air distributed in the



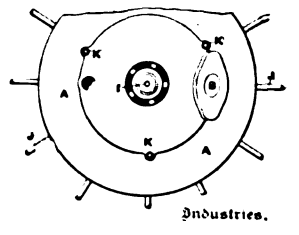


FIG. 1

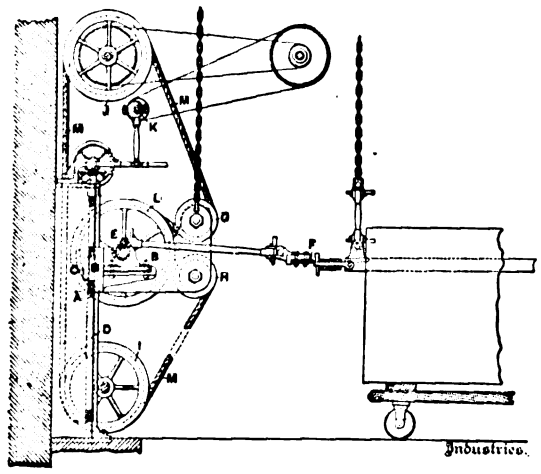

FIG. 2

following manner:—The main blast enters at B to the space C surrounding the blast-nozzle D. From C the blast flows through apertures E, arranged around the nozzle D, and passing up into the tube sucks the grain up from the hopper A. The nozzle D is screwed into the framing, and geared by a pinion F to a hand-wheel G, by which the nozzle can be rotated, and so screwed upwards or downwards, adjusting the space between it and the frame for the admittance of blast to the tube. An auxiliary pipe supplies a blast to the chamber H, from which the air escapes through a central nozzle I and assists the raising of the grain. Radiating pipes J from the chamber H convey blast to the grain surrounding the hopper, and by agitating it tends to keep the hopper full. Pipes K reach to the surface of the grain and allow streams of air to descend into the bulk of the grain to assist the filling of the hopper. Sixteen claims are made.—No. 9568. June 8th, 1889. 8*d.*

GAS RETORTS.—*F. Sanders, St. Petersburg, Russia.*—The retort has the form of an elbow or rectangular tube, the junction of the two limbs being formed of an easy curve. It is heated in a furnace of the usual construction, and its ends fitted with covers, held closed by an efficient arrangement of screws or levers. In the horizontal limb of the retort is provided a mouthpiece or closable opening for the escape of gas to the purifying apparatus. In the vertical limb of the retort are a number of inclined plates or projections, arranged step-like, one above the other. This step-like structure rests in a shallow vessel at the bottom of the retort, the vessel being supported upon pointed legs, so that only a small area is in contact with the retort, to facilitate the removal of the vessel when it is covered by adhesive substances. The retort is heated to redness, and the liquid to be evaporated is passed in through siphons arranged in the cover of the vertical limb. As the liquid enters it drips over the step-like structure, which is heated with the retort, and the liquid is evaporated. The vapours produced remain some time under the influence of a high temperature in the top portion of the vertical limb of the retort, and are transformed into a fixed gas, finally issuing through the mouthpiece in the lower limb. Four claims are made.—No. 11,125. July 10th, 1889. 8*d.*

STONE SAWING MACHINERY.—*S. & W. Dearden, Nelson, Lancashire.*—The class of stone cutter referred to is that in which a horizontal saw frame is employed, the frame being suspended upon four chains and oscillated by a crank and connecting rod. The improvement consists in making the driving mechanism to descend at the same rate as the saw and frame. For this purpose

the bracket B (see illustration) is made to slide vertically upon the post A by a nut C threaded on a rotating screw D. In this bracket B is mounted the crank-shaft E for imparting the oscillating motion to the saw frame F. The pulley L of the crank-shaft is driven by an endless belt M, which passes round the guide pulleys G, H, I and the pulley J, which is rotated by a belt from the motor shaft. Another belt drives the eccentric K, which, by means of a ratchet wheel, pawl, and mitre wheels, rotates the screw D and lowers the bracket B at an equal rate to the descent of the saw frame. Claim: In a stone sawing machine the rising and fall crank-shaft E operating as described.—No. 7525. May 6th, 1889. 6*d.*

STEAM PUMPS.—*S. Northrop, Birmingham.* (*D. Cooper, Philadelphia, U.S.A.*)—An improved method is described in this specification of working the valve of the motive cylinder. The valve is of the ordinary D type, and is worked by a solid plunger or piston having a longitudinal reciprocal motion in the steam chest. The steam chest is bored out to a cylindrical form to receive the plunger, and it is recessed at the centre on the motive cylinder side to form a flat valve seating for the slide valve. A groove is cut in the centre of the plunger to receive the back of the slide valve so that the connection between the valve and the plunger permits the latter to rotate. To work the plunger steam is admitted between it and the ends of the steam chest, so forcing the plunger first to one end of its chamber and then to the other as the piston makes its stroke. Steam is conducted from the cylinder through ports leading from the ends of the cylinder to the spaces behind the ends of the plunger to shift the plunger towards the expiration of each stroke. These ports are opened and closed by the piston of the motive cylinder passing over them, so that as the piston completes a stroke one of the ports is opened and steam admitted behind the plunger to shift the valve. Four claims are made.—No. 10168. June 22nd, 1889. 8*d.*

ROCK BORING MACHINERY.—*W. McNeill, London.*—For the purpose of obtaining the reciprocating motion of the piston rod to which the tool is secured in rock boring machinery, the inventor places between two pistons upon the piston rod a loose sleeve. In this sleeve are cut two slots, whose direction is not coincident with the axial line of the pistons and piston rod, but departs right and left of this line in a spiral direction. In one of these slots is placed the valve for distributing the motive fluid to the cylinder, and in the other slot is a stud fixed to the cylinder to give the sleeve a semi-rotating motion as the pistons make their strokes. The valve is of the ordinary D type, its surface being curved to suit the surface of the cylinder. The steam ports radiate from the centre of the cylinder, and the exhaust port is placed between the two inlet ports. Claims: (1) The use of a valve sleeve formed in one piece, with stud and valve slots shaped thereon, for imparting movement to a distributing valve as described; (2) the use of a distributing valve placed directly in the valve slot as described; (3) the use of portways in the cylinder for admitting and exhausting the motive fluid from the ends of the cylinder as described; (4) the construction of a loose cylindrical valve face with valve ports; (5) the casting of the stud for operating the valve sleeve in one piece with the cylinder; (6) the manufacture and use of the improved apparatus described.—No. 10413. June 27th, 1889. 8*d.*

PRESSURE GAUGES.—*W. Clifford, Norton Woodseats.*—This improved gauge is constructed in the shape of a metal trough, having a longitudinal division plate. The open part of the trough is covered by a sheet of glass, so forming two trough-like channels in conjunction with the division plate. These channels communicate at the lower end by a small hole in the division plate, and at their upper ends are apertures for connecting one channel to the gas whose pressure is to be measured and the other to the atmosphere; the whole thus constitutes a bend. A gauge thus prepared is partially filled with water. The water normally is at equal heights in the channels, but when pressure is exerted by the gas the water is displaced, and its height increases in that channel communicating to the atmosphere, whereas the water in the other is depressed. The difference in height can be read off by a scale upon the glass front and it indicates the pressure exerted. Claims: (1) In pressure gauges constructing the body of two combined troughs of metal or of other material, covered with glass or other transparent substance, and with or without transparent parts as described; and (2) referring to a method of connecting the inlet and outlet tubes to the pressure gauges.—No. 731. January 15th, 1890. 6*d.*

Digitized by Google

COMPOUND STEAM ENGINES.—*R. Edwards, Grantham, Lincolnshire.*—The object of this invention is to simplify the construction of compound engines by reducing the number of connecting rods. Thus in a three or four cylinder engine each piston has its own piston rod, but only two connecting rods are used. In three-cylinder engines, in order to effect this, two of the three cylinders are placed side by side relatively to the centre line of the crank-shaft and their piston rods connected to one cross-head, so that one connecting rod then serves to couple the two pistons to one crank of the crank-shaft. To avoid any injurious side stress on the piston rods the motion blocks are rigidly connected to the cross-head, and are made longer than usual. The third cylinder is placed on one side of the other two and its piston rod connected by a connecting rod to a second crank upon the crank-shaft, or to the same crank if the cylinder is placed opposite the other two. Claims: (1) In horizontal engines having three or four cylinders of different diameters, the arrangement and combination of parts as described; (2) the combination of a locomotive type of boiler and an engine with three or four cylinders of different diameters arranged as described; (3) in horizontal engines having three or four cylinders of different diameters, placing the two smallest cylinders with the smallest at the top and connecting both pistons to one cross-head with long rigid motion blocks, and at the same time placing a third (or a third and fourth) larger cylinder (or cylinders) at the side.—No. 10984. July 8th, 1889. 8*d.*

APPARATUS FOR MAKING AND DRYING MALT.—*A. Gough, Sen., London.*—After the grain has been steeped in the usual manner, it is run into a circular chamber to germinate and to be dried. The chamber has the appearance of a large wheel, and is mounted loosely upon a fixed vertical shaft, for the purpose of being revolved when the grain and malt has to be turned. The chamber is made of iron, its sides being of metal plates, perforated sheet plates, or of woven wire. Perforated air tubes or flues are fixed vertically in the chamber, and can be opened and closed at will to regulate the temperature of the grain. The flues are placed sufficiently near so that in hot weather, with flues open, the temperature will be equal to the malt lying on a floor to the depth of six inches, and with flues closed to the depth of three feet. During hot weather a large fan is used to reduce the temperature of the malt-house. To turn and mix the malt or grain dispersers are arranged in the chamber, and they are operated by its revolution. Claim: A circular rotary aërated chamber or apparatus for germinating of grain and fo the drying and curing of malt.—No. 9276. June 4th, 1889. 6*d*

STEAM VACUUM PUMPS.—*C. Imray, London.* (*The Irrigation Pump Company, Sreeley, U.S.A.*)—This invention relates to the class of steam pumps having two closed chambers which are alternately supplied with steam, which, condensing, produces a partial vacuum in them. Improvements are made in the method of supplying the steam alternately to the chambers. The steam supply is made through a four-way valve, which, by a rotation, may be made to admit the steam alternately to the chambers. Above the valve chamber is arranged a small rotary engine, and its shaft is geared by toothed wheels to the spindle of the valve. Thus by the revolution of the engine the valve is rotated; the speed of the valve spindle, however, is considerably less than that of the rotary engine. The steam employed to revolve the rotary engine passes afterwards into the chambers to perform there the pumping action. Claims: (1) In a steam vacuum pump, in combination with the two vacuum chambers and the passages to them, a rotary valve caused to revolve slowly by a small steam engine, the exhaust steam from which, with or without additional steam, is directed by the position of the valve into one or the other of the two chambers; (2) the construction of the rotary valve above referred to and its casing.—No. 5365. April 8th, 1890. 6*d.*

LOCOMOTIVE BRAKE.—*R. Haddan, London.* (*R. Wiegel, New York, U.S.A.*)—The object of the inventor is to provide a new and improved auxiliary brake for locomotives and railway trains, one which can be applied to stop and check the entire train instantly. On the rear axle of the locomotive is a clutch which can be made by the engineer to engage with a pulley upon the centre of the same axle, and cause the pulley to rotate with the axle. Adjacent to the rear wheel of each car, truck, tender, and locomotive is hung a brake shoe in the usual manner. The brake shoe of the locomotive is connected by a chain to the periphery of the pulley upon its axle, and the other brake shoes are connected by chains to eccentrics upon the rear axles of each car, &c. These eccentrics are connected together, and to the pulley upon the rear axle of the locomotive, by connecting rods. The eccentrics are mounted loosely upon the axles by slotted holes, and are held normally upright by suspending chains secured to the body of the vehicle. Each eccentric carries a clutch which, when the brakes are brought into play, secure the eccentric to its axle. To work the brake the engineer engages the clutch upon the locomotive axle, and causes the pulley upon it to rotate. The pulley, as it commences to rotate, pulls the whole of the eccentrics over by the connecting rods. The brakes are thus drawn against the wheels, and the clutches upon the axles coming into action prevent the axles revolving, and stop the train. The suspending chains prevent the eccentrics from rotating. Five claims are made.—No. 5326. April 8th, 1890. 6*d.*

SINGLE AND DOUBLE ACTION PUMPS.—*L. Grill, Budapest, Hungary.*—In the pump of this specification the piston undergoes a modification which reduces the friction in the barrel and dispenses with the usual suction, pressure, and back pressure valves. In a double acting pump two of these pistons work in the same barrel one above the other. The upper piston is connected to the two outside cranks of a three-throw crank-shaft, and the lower piston to the centre crank of the same crank-shaft; the piston rod of the lower piston passing through the centre of the upper piston. By the revolution of the crank-shaft the pistons are reciprocated in the barrel first towards and then away from each other. Each piston has a perforated funnel or conical-shaped body whose apex is downwards and whose top edge is rather smaller in diameter than the inner diameter of the pump barrel. A rubber conical cup is placed in this perforated body, and so constitutes a valve which will open to the downward motion of the pistons, but remains closed during the upward motion. The edges of these cups overlap the bodies of the valve and thereby make a tight joint with the pump barrel. When the pistons are reciprocated and approach each other the lower piston lifts the liquid and forces that above it up through the top piston which is then descending. As the pistons separate the same top piston lifts the water and forces it on upwards, at the same time sucking it up through the lower piston. In single acting pumps a single piston of the sort described is used in conjunction with a check valve. Claims: (1) The construction and application of preferably funnel-shaped perforated pistons with lining fixed in appropriate position, but being otherwise able to move freely for covering the openings in the piston, said lining acting as valve and being firmly pressed against the interior surface of the pump barrel, thus producing a perfect packing when the piston makes its up stroke; (2) the employment of pistons as described in claim (1) in pairs in such manner that during the operation of pumping the pistons are moved towards and from each other; (3) the application of filtering material such as felt, flannel, and the like in the pumps characterised in claims (1) and (2) so that the pumps deliver filtered water direct; (4) the combination of the improved pistons as claimed with back pressure valves.—No. 5325. April 8th, 1890. 6*d.*

DIAPHRAGM COCK FOR GAS, &C.—*J. & A. Zehren, Paris.*—A fixed diaphragm, or plate, is placed perpendicularly to the axis of the conduit between two separate tubes. This diaphragm is furnished with two orifices to allow the passage of the fluid or vapour. Upon the diaphragm is a circular sliding plate, which slides upon an axis parallel to the tubes, and has pierced in it openings similar to those in the diaphragm. When these orifices correspond, the cock is opened, and can then be closed by turning the sliding plate a quarter of a revolution. To turn the plate a bevel toothed surface is attached to the sliding plate and made to gear with a bevelled toothed wheel, which can be rotated by a hand wheel on the outside of the cock. Claims: (1) The combination of two diaphragms, plane, conical, half-round, in general of whatever form, one movable, the other fixed (this last being independent of or forming part of the conduits) perpendicular to the conduit, pierced with one, two, or several orifices, the revolution of which hinders or allows passage of a fluid, said revolution being obtained either by bevel wheels, endless screw, or other mechanical arrangement; (2) the disposition which consists of employing the double system for resisting strong pressures—*i.e.*, two fixed diaphragms and two movable; (3) the employment of strips inlaid in slots dispensing with adjustment.—No. 14487. September 14th, 1889. 8*d.*

FEED-WATER HEATERS.—*A. C. Moffatt, London.*—In feed-water heaters where the tube-joints are made by indiarubber rings, some difficulty has been experienced in making the joints tight because the rings are liable to be twisted and displaced in putting the tubes in. This the inventor obviates by forming the surfaces between which the rings are compressed of a conical shape instead of at right angles to the axis of the tube. When putting the parts together the tubes will then drop into the sockets or recesses prepared for them without displacing the rings, the end of the tube being guided to its place by the conical recess. Claims: (1) The improvements in feed-water heaters which consist in making the sockets or recesses of a conical form; (2) feed-water heaters as described.—No. 9880. June 15th, 1889. 6*d.*

MARINE ENGINES.—*H. Dunsmuir, Govan, Lanarkshire.*—To obviate the use of separate sets of engines for the several propeller shafts of multiple screw steamers, and to gain the economy and other advantages resulting from the employment of triple or multiple-expansion engines, the inventor arranges a single engine athwart-ships, and connects the different pressure cylinders to separate crank-shafts which are suitably connected to the propeller shafts. In adapting triple-expansion engines to operate the propeller shaft of a single screw, the intermediate and low-pressure cylinders are each directly connected to a crank on a short shaft whilst the high-pressure cylinder is connected to a crank upon the propeller shaft; the three crank-shafts are then connected together by connecting rods. In adapting triple-expansion engines to operate the propeller shafts in a twin screw steamer the high-pressure and low-pressure cylinders are directly connected each to one of the cranks or propeller shafts whilst the intermediate cylinder is connected to a separate crank-shaft, or the arrangement may be varied, and in order that the power and speed of rotation of the two propeller shafts may be equalised and economical working ensured the three crank-shafts are connected together either by crank discs and connecting rods or by toothed or frictional gearing. Claims: (1) The arrangement of multiple-expansion marine engines with the cylinders placed in line athwart-ships, the cylinders being connected singly or in pairs to separate shafts, and the shafts connected or geared to rotate in unison as described; (2) in multiple-expansion engines the combination of a series of cylinders connected singly or in pairs to separate shafts, and a series of connecting rods for connecting together said shafts and transmitting the power from the several cylinders as described.—No. 10665. July 2nd, 1889. 11*d.*

ELECTRICITY.

ELECTRIC ALARUM FOR PRESSURE GAUGES, &C.—*A. Julian, Basingstoke.*—The alarum is constructed to be sounded when the gauge indicates a certain pressure, speed, &c. To the pointer or spindle of the gauge is secured an arm which forms one terminal of an electric circuit having an electric bell in it. In the path of the gauge is a small adjustable stop, forming the other terminal. This stop can be adjusted on the face of the gauge to any pressure. When the pointer travels round the dial and reaches this pressure, the contact arm upon it strikes the stop and completes the circuit. Claim: An attachment to pressure, vacuum, speed, and other gauges for sounding an alarum by means of electricity.—No. 7808. May 10th, 1889. 6*d.*

CHEMISTRY.

MANUFACTURE OF PHOSPHORUS.—*T. Parker & A. E. Robinson, Wolverhampton.* — The material containing the phosphorus is mixed with carbon or carbonaceous material, and the mixture is introduced into a suitable crucible or furnace containing a non-volatile metal which is brought into a state of fusion by the action of the electric current or otherwise. The non-volatile metal is kept in a state of fusion by the passage of a current of electricity through it, and the heat arising therefrom will reduce the phosphorus from the mixture. Instead, however, of passing the current of electricity wholly through the non-volatile metal, it may be conducted through the mixed materials to the metal, when the heat derived from the direct passage of the current will aid the effect of the heat derived from the fused metal. By the passage of the current from an electrode through the mixed materials to the fused non-volatile metal, the heat generated is diffused instead of being locally intense. By the action of the heat derived from the passage of the electric current, the phosphorus is reduced in a vaporous condition, and may be led away from the crucible or furnace, and condensed by well-known means. Claim: The reduction of phosphorus from a mixture containing phosphorus and carbon by the heat derived from an electric current in the pressure of a fused non-volatile metal as described.—No. 10437. June 27th, 1889. 4*d.*

TREATMENT OF TINPLATE SCRAP, &C.—*I. Bang & A. Ruffin, Paris, France.*—It has long since been attempted to separate the tin from tinplate waste and other articles containing tin in combination with other metals, in order to utilise separately the two metals, but the result has been doubtful commercially as regards the tin produced, and practically valueless as regards the utilisation of the iron, as slight traces of tin left in the iron rendered this brittle and useless. It is stated in all chemical works that alkalies dissolve tin, with liberation of hydrogen and formation of protoxide of tin, which is dissolved in the alkalies. If this were the case, the separation of the tin from the iron would be easy, as soda does not attack iron; but this assertion is not entirely confirmed in practice, for if tin is put in contact with alkalies there is no doubt produced a commencement of reaction, with solution of traces of tin, but the attack ceases almost immediately, and the solution of tin does not continue. According to the inventor's investigation, there appears to be produced a kind of polarisation on the surface of the tin, that is to say, a coating of hydrogen is formed, which, combining in the nascent state with the metal, preserves the latter from all subsequent attack. The same phenomenon is produced with the zinc plates of batteries when these are polarised. To counteract this stoppage of the attack of the alkali, and to dissolve rapidly all the tin, the inventors introduce a supply of oxygen. This may be derived from any source; thus the oxygen of the air is sufficient, the solution of the tin being effectually carried out if air in a finely divided state be introduced into an alkaline bath containing the metal to be dissolved, and if the operation be carried on under heating the solution will be sufficiently rapid. To obtain a more rapid action, however, use is made of neutral salts containing a large amount of oxygen, such as nitrate of soda. The process is by preference carried out as follows: Nitrate of soda is dissolved in a soda or potash lye, and the material to be treated is introduced into this bath. The nitrate of soda gives off by degrees all its oxygen to the tin, which dissolves in the caustic soda in the form of metastannic acid, whilst the nitrogen is transformed into ammonia at the expense of the hydrogen of the water, thus continuing the oxidising action. Thus, besides dissolving the tin, caustic soda and ammonia are produced by the above action. The tin exists in the bath in the form of metastannate of soda, and is separated from the soda by hydrate of lime, which takes up rapidly the stannic acid in soda solution and liberates the caustic soda. Claims: (1) The herein-described process for the separation of tin from other metals, in particular from tinplate, whereby the said metals are treated in the alkaline way in the presence of oxygen produced from nitrates or other sources of oxygen; (2) the separation of oxide of tin contained in the alkaline liquor by forming an insoluble stannate by means of caustic lime, and the regeneration of the alkaline liquid.—No. 70. January 2nd, 1890. 6*d.*

MISCELLANEOUS.

FURNACE SLAG.—*T. Hydes, Sheffield.*—The slag as it leaves the furnace is treated with a blast of air or steam which disintegrates it. It is conducted from the furnace to a tube placed vertically over a conical or flat block which acts as a spreader. This spreader is placed in the bell-mouthed nozzle of the blast pipe so that an ascending blast of air or steam will surround the whole block. As the slag proceeds from the tube it falls upon the spreader and drips in a thin sheet from off its edge, when it meets the ascending blast of air and becomes disintegrated. The blast nozzle, &c., are enclosed in a cooling chamber of special construction, arranged to cool the disintegrated slag as it falls after its treatment by the blast. Claims: (1) In the treatment of molten slag for various purposes, blowing the whole of the slag as it is delivered from the conductor or shoot, by means of a blast of compressed air, or steam and air combined, into a disintegrated form, and in such a manner that it will drop into, and by its gravity pass through, cooling passages or tubes surrounded by water; (2) in apparatus for treating molten slag, the construction of a blast nozzle with one or more annular openings or mouths having a central spreading block as described.—No. 10835. July 5th, 1889. 8*d.*

TREATMENT OF FURNACE SLAG.—*T. Hydes, Sheffield.*—In this case the molten slag, as it leaves the furnace, is passed between two rollers kept cool by a constant supply of cold water. It is then conducted by an inclined surface, artificially cooled, to a second pair of rollers, provided, if desired, with ribbed or indented surfaces, to form the slag into cubes or blocks suitable for use on roads, &c. The slag when passed between the second pair of rolls is consolidated, and if the rolls are smooth, it is reduced to a powder suitable for cement, &c. Claims: (1) In the treatment of slag for various purposes, passing the molten slag through rolls, said rolls being made hollow to contain water, for the purpose of chilling and disintegrating, pulverising, or granulating the slag; (2) in the treatment and preparation of slag for various purposes, causing the molten slag to pass through rolls, one or both of the rolls being ribbed, fluted, recessed, or indented, so as to form the slag as it passes through into blocks, cakes, or nodules.—No. 10836. July 5th, 1889. 6*d.*

Copies of the British specifications may be obtained on application to H. READER LACK, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

JAPANESE EXHIBITION AT TOKIO.

We are surprised to observe how little note the industrial public seems to take of the Japanese National Industrial Exhibition, which was opened in April, in the beautiful park at Uyeno, Tokio. There have already been two National Exhibitions in Japan—the first in 1877, the second in 1880. The former, following almost immediately on the footsteps of the civil war in the south, necessarily fell short of the country's capacities. Still, being the first industrial Exhibition ever held in Japan, it attracted much attention. The exhibits showed Japan in a not very lovely light. Her transition period had then fairly set in, and the originality of her artisans was replaced by imitation more faithful than intelligent. This self-effacing tendency displayed itself still more conspicuously at the Exhibition of 1880. The Exhibition of 1880 served the purpose of showing that, while all the old technical skill remained, the manner of its exercise had gone entirely astray, and from that time we may date a renaissance now happily established in all directions. The specimens shown at the present Exhibition enable us to estimate how far Japan can revert to her old routes without departing too much from the requirements of her modern civilisation, and to determine the measure of her probable success in adapting her genius to the needs of the new era. The Treasury's appropriation in aid of the affair is 500,000 yen (£80,000), whereas only 180,000 were given in 1877 and 200,000 in 1880. We learn also that a thousand special tickets have been distributed among foreigners in Europe, America, and Japan, which tickets will confer on their holders exceptional railroad and steamboat facilities.

The buildings in Uyeno Park are nothing from an architectural point of view. Eight acres is the space covered by the roofs, and a visitor passing once along the front of the various stalls will have covered a distance of sixteen miles. These figures apply to the Exhibition proper—that is, to the main edifice where products and manufactures of the day are shown. There is also a fine arts gallery in a separate building on the east of the Park. The general arrangement of the Exhibition will be seen from the accompanying plan. We gave an elevation of the Exhibition in our issue of the 21st of March.

RESEARCH COMMITTEE ON MARINE ENGINE TRIALS.*

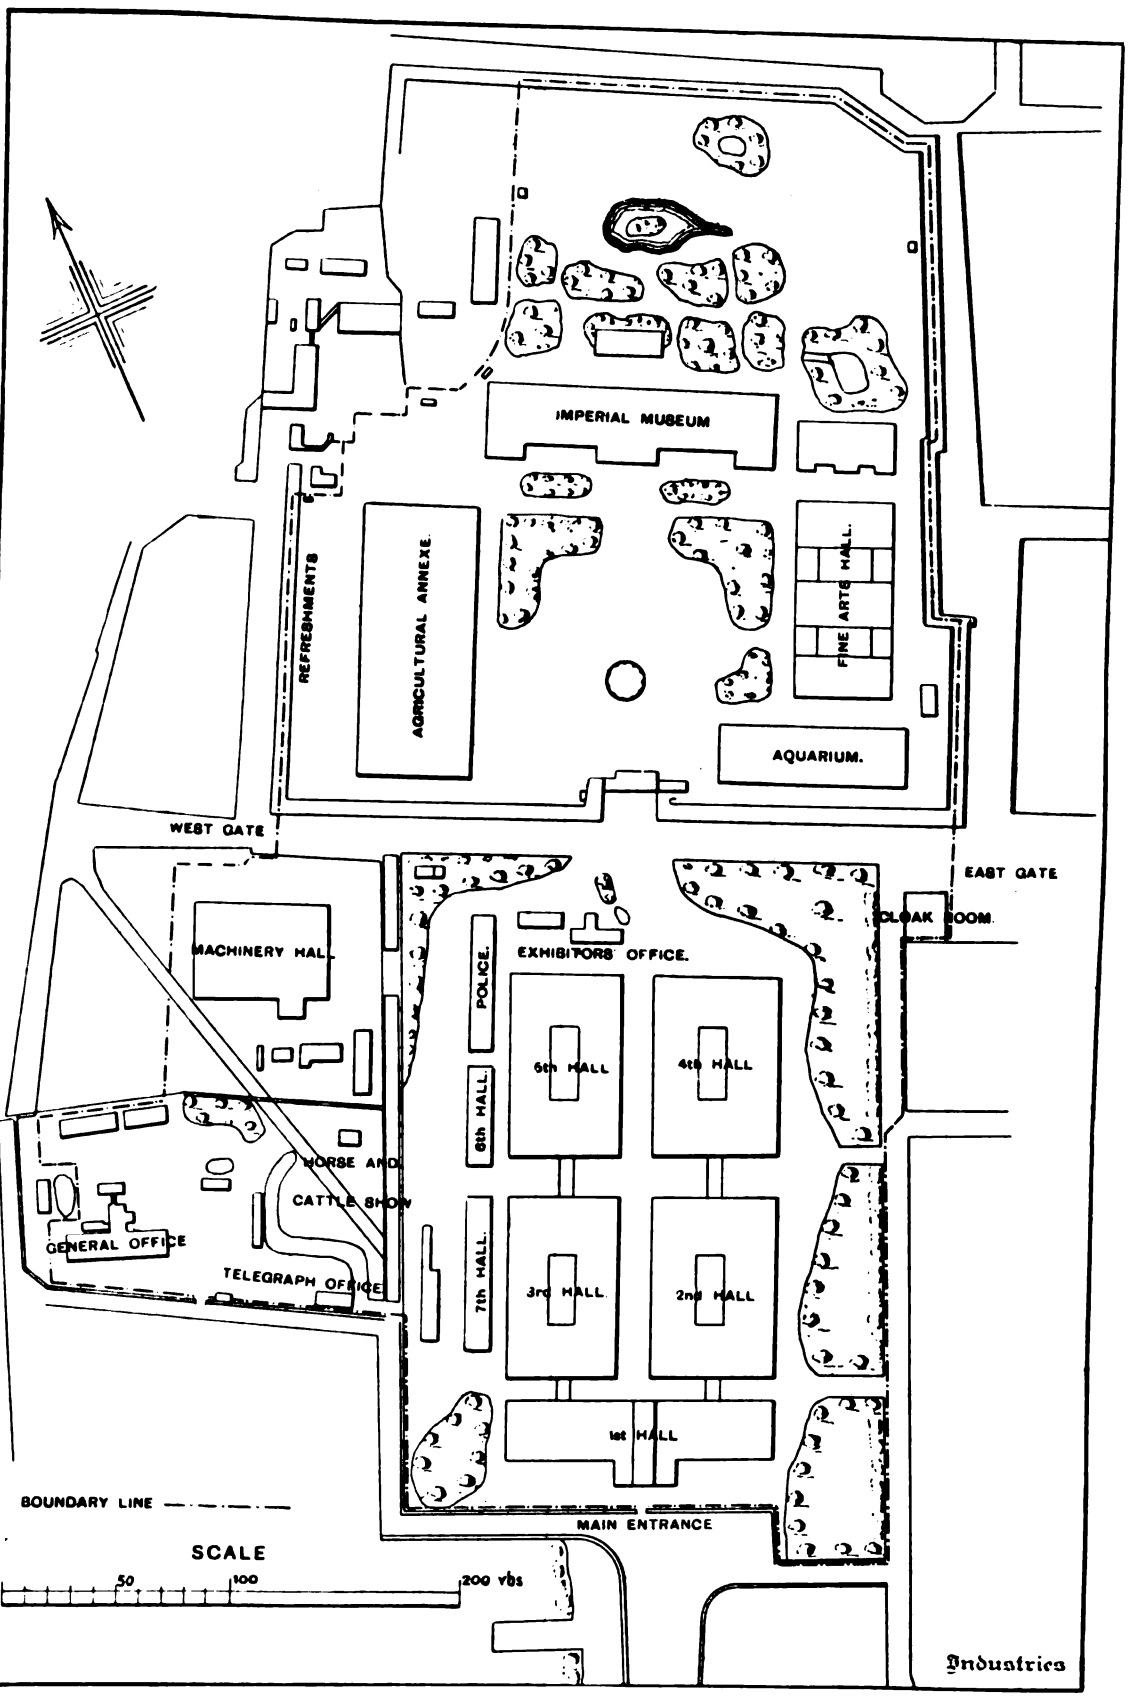
(*Concluded from page 555.*)

3. Trial of the S.S. "Tartar."

Steamer.—This steamship is owned by Messrs. Gellatly, Hankey, Sewell, & Co., and is an excellent example of modern economical engines in a cargo-carrying steamer. She was built in the year 1887 by Messrs. R. Dixon & Co., of Middlesbrough, and engined by Messrs. Thomas Richardson & Son, of Hartlepool, with triple-expansion engines, working a single screw. She is a vessel of 332ft. in length, 38ft. in breadth, and 27ft. in depth (moulded). Her gross registered tonnage is 2,389, and she is classed at Lloyd's 100 A 1. Her draught during the trial was 8ft. 6in. forward, and 15ft. 6in. aft, or 12ft. mean; and her displacement at this draught was 2,250 tons. She was practically without cargo, carrying nothing but water ballast. The trial was made upon the 27th of November, 1889, on a run from the Thames to Portland. The vessel had arrived in London on the 21st of November, after a voyage from Australia; and the boilers were cleaned, and the engines opened out and overhauled before the trial, while the ship was unloading in the docks. Steam was got up on the evening of the 26th November, and the vessel went out of dock about 5 a.m. on the 27th. The trial started at 8.25 a.m., as soon as the vessel was far enough down the Thames to run at full speed, and lasted until 6.30 p.m. The weather during the last part of the run was sufficiently rough to cause the engines to race a little, in consequence of the light draught of the ship. At the time mentioned (6.30 p.m.) the weather had become sufficiently bad to make the taking of accurate observations a matter of considerable difficulty, and it was therefore decided to end the trial, rather than to run any risk of having it spoilt by inaccuracies. In consequence of snowstorms met with going down the Channel, the engines were slowed from 9.52 a.m. to 10.56 a.m., and again for 11 minutes between 12 and 1 o'clock. During these periods the speed was about 64 revolutions per minute, the full speed at other times being about 71 revolutions per minute. Diagrams were taken at the slower speeds, so that they are properly allowed for in the averages. The engines were not stopped at all during the trial; and, with the exception of the intervals named, ran under constant conditions as to position of valve-gear, &c., namely with the main stop-valve and the throttle-valve fully open, and the link-motion slightly linked up.

Engines.—The "Tartar" is fitted with triple-expansion surface-condensing engines, the cylinders being placed in the order, high, low, intermediate, going from forward to aft. The cranks are placed in the sequence—high, low, intermediate. The diameters of the cylinders are 26·03in., and 42·03in., and 68·95in., by gauges. The piston-rods are all 5·5in. diameter. There are no tail rods. The stroke of all three cylinders is 3ft. 6in. The cylinders are jacketed, and there is a separate steam-admission pipe to each jacket. The clearances of the cylinders are given by the makers as 14·51, and 9·25, and 5·10 per cent. The valve-gear is of the link-motion type, with an independent adjustment for the cut-off. The surface-condenser contains 2,250 square feet of tube surface, in 876 tubes of ⅝in. external diameter and of 13ft. 0½in. length between tube-plates. The screw propeller has four blades, and is 16ft. 6in. diameter, with a pitch of 18ft.

Boilers.—Steam is supplied by two double-ended steel boilers with Fox's flues, designed to work at a pressure of 150lb. per square inch. The boilers are 13ft. in mean diameter, and 14ft. 9in. long, each with two furnaces at each end, there being eight furnaces in all. The total grate surface is 161 square feet, each grate being 5ft. 6in. in length and 3ft. 8in. broad. The total heating surface is 5,226 square feet, of which 4,436 square feet is tube surface. The total heating surface is therefore 32·5 times, and the tube surface 27·1 times the grate surface. There are 992 tubes, 3in. diameter outside, and 5 ft. 9in. long over plates. The internal diameter of the funnel is 7ft., and its total height 57ft. above the centre of the furnaces. The total weight of the engines and boilers, including water in condenser, pipes, and boilers, and all mountings, is about 191 tons. The net volume of the boilers is about 4,710 cubic feet.



Duration of Trial.—The duration of the trial from start to finish was 10 hours 5 minutes, or 605 minutes.

Coal Measurement.—The coal was weighed as in the other cases, from 500lb. to 600lb. at a time being put down on each side of each stoke-hold. The trial was started with clean floors, and the time of first stoking from each weighed lot of coal was noted, as well as the time when the whole of the weighed coal was finished. The line of coal consumption plots out as shown in Fig. 11, page 579. The fires were not cleaned during the run. The ashes were weighed after the trial was over, the ash-pits having been cleaned a little time after it commenced. The coal used was Welsh from Perikyber (Glamorganshire) throughout. Coal samples were taken frequently during the run from both stoke-holds, and the final analysis, after a thorough mixture of all these samples, is as follows:—

	Coal as Used.	Dry Coal.
Carbon	87·98 per cent.	88·93 per cent.
Hydrogen	4·22 ,, ,,	4·26 ,, ,,
Moisture	1·07 ,, ,,	0·00 ,, ,,
Ash	3·42 ,, ,,	3·46 ,, ,,
Nitrogen, sulphur, oxygen, &c., by difference	3·31 ,, ,,	3·35 ,, ,,
	100·00	100·00

* Report prepared by Professor Alexander B.W. Kennedy, F.R.S., Chairman of the Committee, for the Institution of Mechanical Engineers, and read at the meeting of the Institution on the 1st ult.

JAPANESE EXHIBITION AT TOKIO.

Digitized by Google

A sample of the ash was also collected, and has been analysed by Mr. Wilson as follows:—

Loss on ignition (= carbon)...	65·53 per cent.
Mineral matter.....	34·47 ,, ,,
	100·00

The calculated calorific value of the fuel is 14,995 thermal units, which corresponds to the evaporation of 15·52lb. of water from and at 212° Fahr., and to an equivalent carbon value of 1·0311b. per lb. The total coal used was as follows:—

After stoke-hold,	port side.....	5,322lb.
,, ,,	starboard side	5,052lb.
Forward ,,	port side.....	4,701lb.
,, ,,	starboard side	4,162lb.
		19,237lb.

This amounts to 31·8lb. per minute, or 1,998lb. per hour. As a check upon this consumption, and in order to see how far it might be affected by any irregularities in measurement at the end of the trial, the consumption has been worked out over a time (in average 560 minutes), at the beginning and end of which the condition of the stoke-hold floors and of the fires was identical, and for this interval the coal consumption works out to 32·08lb. per minute. It has been thought wise to assume, therefore, that the actual coal consumption was 32lb. per minute, or 1,920lb. per hour, the small difference between this and the foregoing figures being probably caused by the increasing difficulty of measurement at the very end of the trial. The total amount of ash taken from the two stoke-holds at the end of the trial was 291lb., but the ash-pits were not cleaned out until some little time after the trial commenced, so that this weight corresponds only to a portion of 6 hours 53 minutes. The ash was therefore equivalent to 0·70lb. per minute, or 42lb. per hour, which is 2·2 per cent. of the total weight of the fuel put on the bars.

Furnace Gases.—A very complete series of furnace gas samples was collected, a sample being collected over mercury by Mr. Wilson every half hour. The analyses of these samples are given in Table IV. The chimney temperatures were read every

quarter of an hour throughout the trial from a mercury thermometer as before. The average reading was 477° Fahr. It remained very fairly constant during the whole trial. The chimney draught was read on a U-gauge at the same time that the temperature was taken, and varied from $\frac{1}{16}$in. to $\frac{1}{4}$in. of water.

Feed-Water Measurement.—The feed-water was measured in the same tanks used for the "Colchester," and already described (see page 554). Each tank lasted in this case from five to six minutes. The total amount of water used was 217,430lb. over a total time of 605 minutes. This amounts to 359·4lb. per minute, or 21,564lb. per hour, but reasons are given later on for supposing that a considerable percentage of this quantity was not actually turned into steam. The continuous supply of feed-water is shown in Fig. 11. At first pumping was carried out by one of the feed-pumps of the engine, but for the last four hours a donkey-pump was used, as it was found to give much less trouble and to be much more conveniently under control. The steam for this donkey-pump was supplied from the main boilers. The steam made by the boilers all went to the main engines, steam being kept up in the donkey boiler for all auxiliary engines; and the pipes and connections having been carefully examined, in order to see that no unintentional communications existed. The water-level in the boilers was, on the average, 1¼in. lower at the finish than at the start of the trial. This corresponds to a total of 1,874lb. of water, or about 0·86 per cent. of the whole feed; this amount has been added to the quantities given above. It may be interesting to notice that an error of ½in. in reading the level in one boiler in a case like this would make a difference of about 375lb., or under 0·2 per cent. of the water used.

Power Measurement.—Indicator diagrams were taken every half hour from each end of each cylinder as before. There were thus twenty-one complete sets of diagrams, or 126 single cards taken in all. The indicators used were those lent by Messrs. M'Innes & Cairns, which were used also for the "Colchester." The following are the mean effective pressures in the cylinders in pounds per square inch:—

Cylinder.	Top.	Bottom.	Mean.
High-pressure.....	35·74 ...	38·04 ...	36·89
Intermediate	19·92 ...	20·23 ...	20·07
Low-pressure.....	7·19 ...	7·18 ...	7·18

These pressures correspond to the following indicated horse-powers:—

High-pressure cylinder	273·7
Intermediate cylinder.....	408·5
Low-pressure cylinder	395·2
Total indicated horse-power.....	1,087·4

The maximum indicated horse-power given by any one set of cards was 1,296·7, which occurred at 8.45 a.m., with 73·2 revolutions per minute, and 146lb. of steam. The minimum indicated horse-power by any one set of cards was 719·3, at 10.10 a.m., with 61·4 revolutions per minute, and 135lb. of steam. From the 126 diagrams which were taken during the trial a mean diagram has been plotted for each of the three cylinders, and these are given in Fig. 14. The continuous variations of boiler pressure and cylinder mean effective pressures are shown in Fig. 13, and of horse-powers and speeds in Fig. 12.

Speed.—The counter was read every quarter of an hour. The total number of revolutions made was 42,350 in 605 minutes, or exactly 70 revolutions per minute. The maximum number of revolutions per minute for any quarter of an hour at full speed was 73·8, and the minimum 70·3 revolutions per minute, while the average speed during the time that the engine was slowed down was 63·7 revolutions per minute.

Steam Jackets.—As has been already mentioned, each jacket received steam through a separate valve. The connections from the jacket-drains to the hot-well were broken, and all three jackets were made to drain into a small tank placed at the back of the engine; and the rate at which the jacket-water collected in this tank was measured fourteen times during the trial, on most occasions for nearly a quarter of an hour continuously. The water collected in this way amounted in all to 2,476lb. in 175 minutes, or 14·15lb. per minute, which is 3·94 per cent. of the total feed. This quantity is, of course, included in the total feed measured through the tanks. It was not possible to jacket the high-pressure cylinder with steam of full boiler pressure, and under these circumstances it did not appear advisable to allow any steam to pass into that jacket, which was accordingly shut off. The quantity of steam given is, therefore, from the intermediate and low-pressure cylinder jackets only.

Pressures, &c.—The mean barometric pressure during the trial was 29·6in. of mercury, or 14·6lb. per square inch. The mean boiler pressure was 143·6lb. per square inch by the pressure-gauge in the stoke-hold, and 140·4 by that at the engine. The pressures in the high-pressure, intermediate, and low-pressure valve chests, were respectively 131·4, 46·1, and 3·8lb. per square inch above the atmosphere respectively. The pressures in the steam jackets of the intermediate and low-pressure cylinders were 52·5 and 14lb. per square inch respectively. The cock admitting steam into the high-pressure jacket, although nominally shut, allowed enough steam to leak through to enable the gauge to show pressures varying from 0 to over 50lb. per square inch. The actual amount of water coming from the high-pressure jacket-drain, however, was too small to affect appreciably the quantities given in the last paragragh. The mean vacuum was 26·2in. of mercury by gauge, which corresponds to a mean absolute back pressure in the condenser of 1·7lb per square inch. The mean initial pressure in the high-pressure cylinder was 121·8lb. per square inch above the atmosphere, and the mean back pressure in the low-pressure cylinder was 10·5lb. per square inch below the atmosphere, which corresponds to an absolute back pressure of 4·1lb. per square inch in the cylinder.

Boiler Efficiencies.—The mean rate of combustion in the furnaces was 11·93lb. of coal per square foot of grate surface per hour, or 0·3671b. per square foot of total heating surface per hour. The total amount of feed-water pumped into the boilers was at the rate of 11·23lb. per lb. of coal. As the feed entered the boiler at an average temperature of 101° Fahr., and the temperature corresponding to the mean boiler pressure was 362° Fahr., each lb. of steam must have taken up 1,123 thermal units; and the equivalent evaporation from and at 212° Fahr., had the whole of the feed-water been turned into steam, would, therefore, have reached the very high figure of 13·06lb. of water per lb. of coal. The equivalent amount of heat utilised per lb. of coal would be 12,610 thermal units, or say 84·3 per cent. of the whole calorific value of the fuel. Such a figure, although unusually high, is of course not in the nature of things impossible; but if it really represented the evaporation in this case, it would follow that the unusual economy of the boilers was accompanied by an unusual want of economy in the engines. Fortunately the measurements made were sufficiently complete to enable it to be stated positively that (from whatever cause) the whole of the water pumped into the boiler was *not* turned into steam. The very complete and uniform series of samples of chimney gases, of which the analyses have been given in Table IV., enable the calculations connected with them to be made with considerable exactness and certainty. The weight of dry air per lb. of coal calculated from these analyses works out to 31·6lb., so that the total weight of furnace gases per lb. of coal would be about 32·6lb. The gases have been raised in temperature from the temperature of the outer air, say about 55° Fahr., to 477° Fahr., the chimney temperature. Taking the mean specific heat of the gases as 0·238, this corresponds to a loss of 3,307 thermal units per lb. of coal, or 22·1 per cent. of the whole calorific value of the fuel, including the raising through the same range of temperature of the steam formed by the combustion of the hydrogen in the fuel. The loss due to evaporation of the moisture in the fuel is so small as to be negligible, and in no one of the twenty analyses was any carbonic oxide found to be present in the chimney gases. The loss by radiation was no doubt considerably less than in the "Colchester" (the stoke-holds being very much cooler), but taking it as low as 8 per cent., and adding to it the 22 per cent. carried away by the chimney gases, it seems certain that the maximum boiler efficiency which can have been reached cannot have exceeded 70 per cent. This would correspond to an evaporation of 10·8lb. of water from and at 212° Fahr. per lb. of coal, which is about 83 per cent. of the apparent evaporation mentioned above. It is, moreover, to be noted that on the original log sheets the reporter finds in five different places memoranda made at different times by different assistants who were taking indicator diagrams, that they were unusually troubled by the amount of water which came through the indicator cocks.

Coal Consumption.—The total coal burnt, namely 1,920lb. per hour, corresponds to 1·77lb. per indicated horse-power per hour. This is equivalent to 1·82lb. of carbon-value per indicated horse-power per hour.

Engine Efficiencies.—Although the total quantity of water pumped into the boilers per indicated horse-power per hour amounted to $\frac{21,564}{1,087·4}$, or at the rate of 19·83lb. per i.h.p. per hour the quantity of *steam* consumed could not have exceeded, as the figures in the preceding paragraph show, 16·5lb. per i.h.p. per hour. The difference must be attributed to priming.

Total Efficiency.—The combined efficiency of the boiler and engines, or ratio of the heat turned into work to the total heat of combustion, was 9·7 per cent.

Steam from Indicator Diagrams.—The following are the results of measurements made upon all the indicator diagrams taken, to ascertain the proportion of steam accounted for by them. The actual weight of feed-water used per revolution was 51·3lb.

Proportion of Steam accounted for by Indicator Diagrams.	Lbs. per Revolution.	Percentage of Total Feed.	Percentage in Jackets or present in Cylinder as Water.
Steam present in high-pressure cylinder, after cut-off, when the pressure was 115·4lb. per square inch above the atmosphere	Lbs. 2·32	Per Cent. 45·2	Per Cent. 54·8
Steam present in intermediate cylinder when the pressure was 33·4lb. per square inch above the atmosphere	2·53	49·2	50·8
Steam present in intermediate cylinder when the pressure was 9·4lb. per square inch above the atmosphere	3·03	59·0	41·0
Steam present in low-pressure cylinder near end of expansion when the pressure was 7·1lb. per square inch below the atmosphere	3·12	60·7	39·3

The Research Committee on Marine Engine Trials, in presenting to the members of the Institution their second report upon their work, desire it to be quite understood that they do not at all look upon their duties as yet ended. They are glad to be able to think, however, that they have already done enough to show that engine trials can be conducted on board ship on as complete a scale and in as scientific a method as on land (although, perhaps, with greater difficulty and discomfort to the observers), and that this can be done without any undue interference with the normal working of the ship or engines. The Committee wish also to say that they hope, when their work is completed, to present to the members a comparative summary of all their experiments, in the discussion on which many points as to the influence of design on economy may be better discussed than at present. Their future work may be much helped, however, by suggestions made at this stage as to improvements in the methods or in the instruments used, or as to the best means of ensuring the accuracy or measuring the errors of gauges, indicators, &c. They would also point out that there still does not exist any satisfactory means for measuring the *effective*

Digitized by Google

horse-power of a marine engine in its actual work—*i.e.*, the power actually expended in pushing the ship forward (as measured by the thrust of the propeller and the speed of the ship), nor for measuring the quantity of the condensing water, a knowledge of which is necessary to enable a "heat balance" for the engines to be made.

The comparative results obtained in the four trials as yet made by the committee were given in a table on page 435 of our issue of the 9th ult.

THE EXPERIMENTAL VALUE OF THE STEAM JACKET.

The Research Committee appointed by the Institution of Mechanical Engineers to investigate the question of the value of the steam jacket recently issued their first report, and it contains an interesting collection of actual experiments, collated, as far as possible, from all the data published in England and elsewhere, with reference to this subject, up to the present time. Those experiments only are recorded which were made on the same engine with and without steam jackets.

The trials are divided into three groups, in which single cylinder non-condensing engines, single cylinder condensing engines, and compound condensing engines were tested. A great divergence is observable in the results obtained, but this is not to be wondered at if we consider the varying methods in which the steam jackets have been applied in the different cases and countries. In some of the experiments the steam jackets were such in name only; sometimes water and sometimes air were doubtless allowed to accumulate; the steam pipes supplying the jackets were often much too small, and very few cylinders had steam pressure gauges to their jackets. Occasionally the steam in the jackets was made to circulate, while in most cases it was stagnant. The steam pressures, the piston speeds, and the i.h.p. all greatly differed, and there were vertical and horizontal, small and large engines, with and without expansion. Notwithstanding these variations there is much worthy of study in the experiments, and, speaking generally, we may say at the outset that the results are decidedly favourable to the employment of steam jackets when *properly* applied. In nearly all cases the quantity of the jacket water is given. The results are expressed concisely in the tables, and the economy effected by the use of the jacket is shown in the smaller percentage of feed water required.

Having thus briefly indicated the scope and importance of the report, it may be interesting, before describing some of the experiments, to revert briefly to the first mention made of the steam jacket by the original inventor, James Watt. He does not appear to have left on record any experiments on steam-jacketed engines; at least none such have come to our knowledge, though we shall be glad to have particulars of them, if they exist. It is certain, however, that he laid down the principle of the steam jacket, and took out a patent for it, dated March 12th, 1782. In his specification he describes the jacket in the following words:—"The whole cylinder, or as much of it as possible, is enclosed in a case containing steam or otherwise is maintained of the same heat as boiling water or of the steam from the boiler." Thus his original idea was solely to keep the cylinder warm for very low-pressure steam.

Single Cylinder Non-Condensing Engines.—We now propose to make a few remarks on those experiments in the report which possess special interest, and will begin with the series of single cylinder non-condensing engines. The earliest experiments on steam jackets appear to have been made in France about the year 1846, when MM. Thomas and Laurens found that with 120 i.h.p. there was an economy of 8 to 10 per cent. in the feed water consequent upon the use of the steam jacket. Very few particulars, however, were published, or are now obtainable, with respect to this trial. The subject had already engaged the attention of M. Hirn, but he did not publish his results till some years later. The next set of experiments was made by Messrs. Farey & Bryan Donkin, Jun., in 1874, at Bermondsey, on a single cylinder beam engine, running slowly. The boiler pressure was about 45lb., and the economy effected varied from 11 to 21½ per cent., according to the number of expansions used, the number of revolutions being the same in each trial. Here the whole of the steam passed through the jacket, and this was perhaps among the first trials in which the jacket steam was made to circulate on its way to the cylinder. About the same period a series of experiments were made at Lille in France by M. Cornut. The expansions varied from 7½ to 20, the i.h.p. from 80 to 136, and the gain recorded by the use of the jacket was from 14 to 19½ per cent. This was confirmed by other experiments later in the same year and at the same place, with an expansion of 10, giving an economy of 19 per cent. Next in chronological sequence followed two experiments on marine engines, made in America, by Messrs. Loring & Emery. The jackets were supplied from the bottom of the steam chest. The steam pressure was 68½lb., the i.h.p. from 170 to 212, and the economy effected was a little over 10 per cent. A large number of experiments on a locomotive engine were made by M. Borodin at Kieff, in Russia, from 1881 to 1883. The jacket was supplied by a separate pipe. Six trials, with and without a steam jacket, were carried out with different pressures of steam, and the gain in economy was found to vary from 7 to 22½ per cent. Lastly, we have to mention an important series of experiments carried out in 1883 by M. Delafond, at the Creusot Works, in France. Twelve sets of trials were made, or twenty-four in all. The jacket was supplied with steam by a small pipe, and the pressures were varied, as also the number of expansions. The revolutions were about the same in all the trials, giving a mean of 61 per minute. Taking the results generally, they showed an economy varying from 22 per cent. with 6 expansions to as little as 1 per cent. with full steam.

MARINE ENGINE TRIALS.

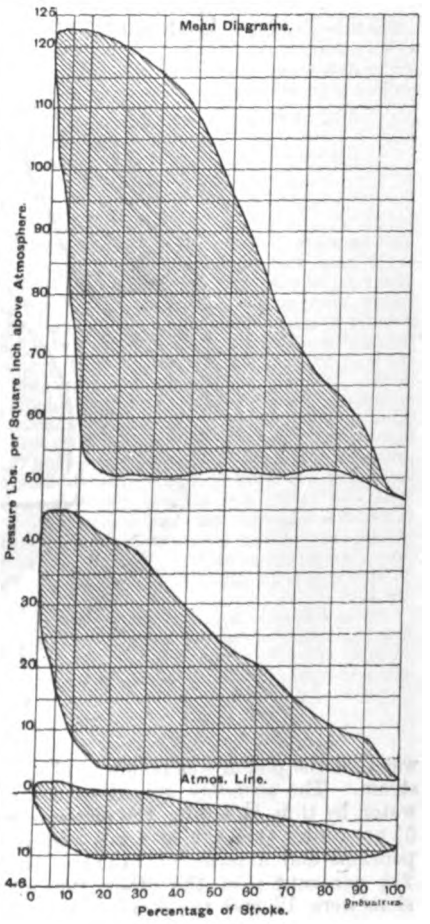

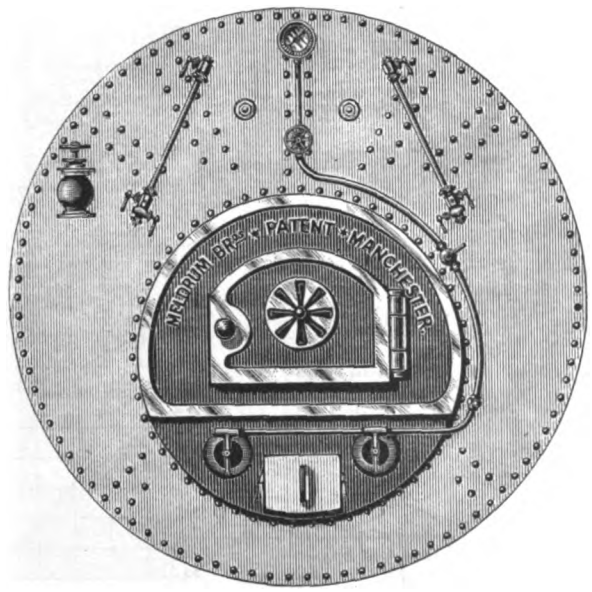

Fig 14.

Mention has already been made of M. Hirn's investigations of the laws governing the phenomena of the steam jacket. Among the many experiments he carried out, he reported upon two made with this type of engine, in conjunction with his colleague, M. Hallauer. The results may be briefly summed up. The economy in consumption of feed water was 23½ per cent., the number of expansions 10, and the i.h.p. was 56 without and 83 with a steam jacket. This was the mean of the economy usually obtained by M. Hirn. In four trials made by Mr. G. B. Rennie, in 1873, a saving of 32 per cent. was effected with an i.h.p. of about 40. A series of eight experiments were made by Messrs. Loring and Emery, of the United States Navy, in 1875, upon the engine of a steamer (stationary at the time). The number of expansions varied from 1½ to 7; the i.h.p. fluctuated with the boiler pressure, ranging from 87 with a pressure of 14½lb. to 348 with a pressure of 67lb. The mean of the economy obtained was 11 per cent. Another important series of trials were made in 1878 by MM. Meunier and Keller, on a Corliss engine, at a cotton mill, near Mulhouse. The peculiarity of these experiments elucidate the theory of the steam jacket than Hirn, and the exhaustive researches he undertook about 1855 threw more light on this subject at the time, than the labours of any other scientific worker. In Combe's experiments the number of expansions was 20. In one trial the jackets were supplied with the whole of the steam passing to the cylinder, in the other the steam was introduced through a small pipe only. In the first case the economy in feed water was 42, and in the last 27 per cent. Here the advantage of the circulation of the jacket steam is brought out. In 1860 four experiments on this type of engine were made by Mr. Isherwood at New York. The number of expansions in the first were about 5, and the gain in economy 31 per cent. The second set of trials were made with a very large beam engine, only the body being jacketed; the number of expansions was 1½, the i.h.p. 352 and 361 respectively, and the economy effected 2½ per cent. This very small gain is perhaps referable to the rather large size of the cylinder and the small boiler pressure. Two sets of experiments made in 1870 afford useful points of comparison. One was carried out upon a large Cornish Bull pumping engine by Mr. Bryan Donkin, Jun.; the number of expansions was 4, the i.h.p. showed a mean of 157, and the economy shown was 13 per cent. The other trial was made by Messrs. Farey & Bryan Donkin, Jun., upon a small beam engine; the i.h.p. was 7¾ and 9¼ respectively, 1¼ expansions were used, and the gain shown was 19 per cent.

BOILER FURNACE FOR BURNING BREEZE.

CONSTRUCTED BY MESSRS. MELDRUM BROTHERS, ENGINEERS, CATHEDRAL YARD, MANCHESTER.

FRONT VIEW OF BOILER.

LONGITUDINAL SECTION THROUGH BOILER AND FURNACE.

was that the piston was hollow, and could be filled with steam. The economy gained in consumption of feed water by thus jacketing the piston only was from 2 to 5½ per cent. One set of trials was made with 5½ expansions and a mean of 143 i.h.p., the economy being 21½ per cent.; in the other, the number of expansions were 12, and the economy was 30 per cent., with the jacket proper. Among the last on the list of trials we give of single cylinder condensing engines, are a large number of experiments, forty-six in all, made by M. Delafond, at the Creusot Works, in France, in 1883. They were carried out on the same engine as that used for the twenty-four non-condensing experiments already recorded, except that a condenser was added. None of the trials exceeded two hours in duration. The boiler pressure varied from 35lb. to 110lb., and the number of expansions ranged from 13½ to 1, being sometimes slightly higher without than with a steam jacket. The number of revolutions was about 59 or 60 per minute, the i.h.p. from 68 to 212. With such varying conditions, it will not appear surprising that there were great fluctuations in the percentage of gain of feed water. The highest economy was 26½ per cent. with 141 i.h.p., the lowest 0·47 per cent., while in one case the consumption of feed water was 0 61 per cent. less without than with steam in the jackets. Before passing on to the last series of trials, we must notice three carefully carried out experiments. The first was made at Dalkeith, in 1877, by Mr. Lavington E. Fletcher. The mean of the expansions used was nearly 4, of the i.h.p. 181, and the percentage of feed water 15½ less with the steam jacket. The second was undertaken at Chatham by Mr. J. G. Mair, under almost the same conditions; the economy obtained was 16½ per cent. The third was made by M. Farcot, in France, in 1879, and showed an economy of 17 per cent. with from 13 to 15 expansions.

Compound Condensing Engines.—In reviewing the third and last series of experiments, it will be at once apparent that the conditions of trial in this type of engine were more complex. Sometimes one, sometimes both cylinders were jacketed, while the jacket in either the high or the low pressure cylinder was suppressed, as occasion served. The earliest trials on compound condensing engines of which we have succeeded in obtaining particulars were undertaken by Hirn on his celebrated engine, at Logelbach, near Colmar, in 1854 and 1855. The number of expansions were 4, revolutions per minute 23½, and the same economy of feed water was recorded as in his previous trials, namely 23½ per cent. We pass next to two series of experiments made on the same engine, in 1859 and 1870, by Messrs. Farey & Bryan Donkin, Jun. The boiler pressure was in the first 41lb., in the second 45lb., and the number of revolutions about the same in both. Five and a half expansions were used, and the percentage of economy in feed water was 28½ per cent. In the second trials the expansions were 10, and the economy 38½ per cent., the highest figure attained in this record of experiments. A third series was undertaken by the same experimenters in 1868, and conducted under three different conditions, with and without steam in the jackets, and with steam admitted through a small pipe at a pressure of 4lb. When the steam was admitted freely, the economy was 31 per cent.; when the pressure was reduced to 4lb., the gain was only 13⅓ per cent. An important set of twenty-two experiments were carried out from 1875 to 1881, on a small engine at Bermondsey, by Messrs. Farey, Bryan Donkin, Jun., and Salter, to ascertain the effect of the steam jackets under various working conditions. The boiler pressure was uniformly 42lb. and the number of revolutions 98. Where the engine was running without steam in the jackets, the i.h.p. was 8¾. With steam admitted into the high-pressure jacket only, the h.p. was 7·8, and the economy in feed water 25½ per cent. Where it was allowed to enter the low-pressure jacket, the mean of seven experiments gave 10 i.h.p. and a saving of 29 per cent. In eight experiments the steam was admitted into both jackets; here the i.h.p. was 9½, and the gain in percentage of feed water 34.

Four trials on a pumping engine, and on a beam engine driving a flour mill, were made in August and December, 1881, by Mr. John G. Mair. The pumping engine showed the high percentage in economy of feed water of nearly 35, with 75 i.h.p., and a mean boiler pressure of 45lb.; the number of expansions varied from 9 to 15. In the other experiment from 7 to 9 expansions were used; the mean boiler pressure was 73lb., the i.h.p. 268, and the economy effected 8¾ per cent. Professor Kennedy and Mr. Bryan Donkin, Jun., made two trials in 1887, at the London Hydraulic Power Pumping Station, with a surface condensing vertical inverted engine. The number of expansions were 7, the i.h.p. varied from 157 to 168, and the gain shown in feed water was 15⅓ per cent.

In the last set of experiments in the series we are examining, the details were more complete than in others on the list. They were made by Professor Kennedy upon the same experimental engine, at University College, London, as was used in the twenty-two experiments described among these compound condensing trials, with which they tallied well. The experiments were conducted with extreme care, and a large number of data obtained bearing on the different phenomena exhibited in the working of a steam engine. Both cylinders were jacketed, and the steam circulated through the two jackets before entering the high-pressure valve chest. The steam and water in both cylinders, in the jackets and steam pipes, the trap water, radiation and condensation, were all carefully measured; the boiler pressure varied from 39lb. to 95lb. The smallest ratio of expansion was 3 to 1, the largest 5·92; the i.h.p. varied from 7¼ to 13¼. The least economy in feed water obtained with both jackets in use was 4⅓ per cent. with 13 h.p. and a ratio of expansion of 3·60; the highest gain by the jacket was 38 per cent. with the same horse-power, and the number of expansions used was 8·43.

We congratulate the Institution of Mechanical Engineers on this Report, and shall look for further experiments with much interest. We hope the Committee will give us more well-recorded facts relating to modern engines.

MACHINERY AND METALS IN HUNGARY.

HUNGARIAN statistics are in a backward condition, and the latest on the subject of machinery which have been available to the British Consul at Budapest are those for 1888. The imports of machinery for that year amounted to £561,725, of which the principal items were:—

Locomotives, &c.	£42,892
Sewing machines	116,845
Thrashing „	44,779
Mowing „	4,860
Sowing „	11,728
Ploughing „	47,969
Pumps, cranes, presses, &c.	50,571
Parts of machinery	212,119

Hungary is making great efforts to supply her own agricultural machinery, and it is stated that out of £660,000 worth of agricultural machinery required, £479,000 worth was furnished by Hungary herself. There are branches of several English agricultural machinery houses existing in Hungary, and it is possible that a considerable proportion of the native manufacture is effected by these establishments. The works of the Royal Hungarian State Railway is one of the chief manufactories in machinery, and have, it is said, been able to turn out, among other articles, about 100 steam thrashing machines of 6, 8, and 10 h.p. Measures will shortly be taken by the Government for extending the activity of the machinery department of this railway. In mowing and binding machines there was a small demand, and attention is drawn to the valuable new mowing and binding machine, the "Massey," from Canada, which is expected to have great success in Hungary. Steam ploughs are made by Messrs. Ganz & Co. As an extension of beetroot cultivation is expected, attention is being specially directed to implements connected with this industry. The larger and more elaborate machines have still to be imported from abroad, and there is a considerable import of complicated or delicate parts of machinery, which are put together in Hungary. Last year's iron trade was good, and the sudden increase in the demand on home producers for manufactured goods could scarcely be met owing to the want of sufficient raw material.

MELDRUM'S BREEZE FURNACE.

A FRONT view and longitudinal section is given herewith of a fuel-burning arrangement made by Messrs. Meldrum Brothers, Cathedral Yard, Manchester, as applied to a boiler furnace in which breeze or fine coal is used as a fuel. The system is one of forced draught with a closed ashpit, and a pressure equal to about ¾in. water gauge is obtained. The ashpit is closed by a frame in which there are two circular openings, to each

Digitized by Google

of which is fitted a trumpet-shaped tube, as shown in the sectional view. In the frame, fitted to each of the openings, a cross-bar or tube is formed, by which the steam is admitted to a nozzle placed exactly in the centre. To the inner part of the opening the tube is fixed, so that when the steam is turned on a powerful induced air current is created. The steam connection is clearly shown in the front view. In the centre of the frame closing the ashpit an aperture is provided by which the ash can be withdrawn. There is a raised face surrounding this aperture, which is planed all over, and the door is very ingeniously arranged to be self-sealing. It has at each side a lug, which is tapered or wedge-shaped, and which fits into a similarly shaped staple cast with the frame. The weight of the door is thus sufficient to press its inner face—which is also planed—into close contact with that of the frame, thus establishing an air-tight joint without the employment of screws in any form.

The shape of the blower tube has been settled by the makers after a long series of experiments, and they claim to have obtained tubes of proportions which give the maximum of efficiency. The steam nozzles are only drilled with holes of a small size, so that the amount of steam used is comparatively small. We inspected a furnace in which breeze of a very inferior character was being used, and the combustion was very perfect—no difficulty being experienced in rapidly raising the required steam pressure. The fire was a thick one, but in spite of this it was burning well throughout its length. In order to facilitate the use of fine fuel the bars are closely set, and the resultant ash and clinker contain nothing of value as fuel.

The makers are applying blowers of this type to many purposes, such as agitating liquids, forming either an air pressure or vacuum as desired, and have a number of applications of interest in experimental work at the above address. With breeze and similar fuel they have been very successful, and they state that the steam consumption is very low having regard to the effectiveness of the apparatus.

MANWELL'S "READY LIFE SAVER."

In section 21 of the Merchant Shipping Act, 1876, it is stated that "every sea-going passenger steamer and every emigrant ship shall be provided, to the satisfaction of the Board of Trade, with a proper supply of lights inextinguishable in water and fitted for attachment to life buoys. . . . . If any such steamer or ship goes to sea from any port of the United Kingdom without being so provided as required by this section, for each default in any of the above requisites the owner shall, if he appears to be in fault, incur a penalty not exceeding one hundred pounds, and the master shall, if he appears to be in fault, incur a penalty not exceeding fifty pounds." The inextinguishable lights referred to usually consist of a chemical substance (phosphide of calcium), enclosed in a tin cannister, which must be of sufficient strength to remain perfectly air-tight and water-tight under all conditions of climate. The efficiency of the lights is absolutely dependent upon freedom from moisture—even of that contained in the atmosphere—until the time of use, when it is necessary to prick a hole in each end of the tin preparatory to its being thrown overboard. On water entering the tin, its action on the chemical substance causes ignition and a bright flaring light, visible for several miles at night, accompanied by dense smoke perceptible at a great distance in the daytime. The person to be saved having grasped the buoy, the rescuing vessel or boat is directed to the position with probably successful results.

The procedure hitherto followed may generally be gathered from the circumstances attending the lamentable death of General Sir Howard Elphinstone, a passenger on board the s.s. "Tongariro," as described by the chief officer, who said, "I was startled by the cry of 'man overboard!' I rushed to the telegraph and reversed the engines; then got ready, and threw a lifebuoy overboard. When I say 'got ready,' I had to punch two small holes in the tin case containing the light, as without a light we should not have been able to find it. Of course, for some time after the buoy was thrown, the ship continued to go ahead, so all we could do was to get the boat ready, and, after passing the buoy again going astern, we lowered it, and, with the second officer in charge, they pulled round and about the place, but no sign was ever seen of the unfortunate man." Assuming that two minutes elapsed between the cry of "man overboard" and the buoy being "got ready" and thrown overboard, and the ship's speed to have been 14 knots, there must have been an intervening space of about half a mile between the drowning man and the buoy.

It therefore goes without saying that any appliance that would materially reduce these intervals of time and distance must commend itself to the Board of Trade and shipowners as worthy of adoption, and one has recently been brought to our notice in the form of Manwell's "Ready Life Saver." This is shown in Figs. 1 and 2, and by a simple half turn of a handle—an action occupying only a fraction of a second—it punches the light canister at both ends and discharges the canister and the attached buoy. With one of these placed overhanging the water at each end of the vessel's bridge, and, therefore, in close proximity to the officer of the watch, an interval of, say, two seconds as a maximum would suffice to place the buoy and light in the water, with results much more favourable than those obtaining under the old plan of "getting ready."

A very small percentage of the deaths by drowning at sea is known to the public. It is only when consequential mishaps, such as rescuing boats capsizing on being lowered, some great casualty involving many lives, or when some deed of heroism has been performed, that publicity is given to the circumstances. With Manwell's apparatus on board the first duty of the officer of the watch would be to instantaneously discharge the buoy and light, which would fall within a short distance from the man overboard, whatever might be the speed of the vessel at the time. As will be seen from Figs. 1 and 2, the apparatus is very simple in design, and is, therefore, not likely to get out of order. It consists of a T-shaped board, on the top of which is fixed a box for holding the canister. At each end of the box are arranged needles or prickers E, which are actuated by a handle A through the levers B. The life buoy, when ready for action, is suspended from a rod F, one end of which is fastened to the hinged bottom G of the box, and the other end rests upon the toe D. The mode of using the apparatus is as follows:—The handle A is turned through 90°, which causes the prickers E to perforate the canister at each end. A further turn of the handle causes the prickers to recede, and just after the points are clear of the canister the toe D relieves the lever F, which then assumes a vertical position as shown by the dotted lines. The life buoy cord slips off F, and the canister falls with the buoy into the water, ignites, and gives out the necessary light. The turning of the handle A need only be the work of a second, or even less. Our illustration shows the body of the apparatus as made of wood, but in the Navy pattern we think metal would be a preferable material.

The apparatus has already been adopted by the Atlantic Transport Line of steamers, is under the consideration of the Elder Brethren of the Trinity House, and negotiations are pending for its application to some of the leading passenger lines. It can be seen at the offices of Messrs. Manwell & Glen, 8, Great Winchester Street, London, E.C.

MANWELL'S "READY LIFE SAVER."

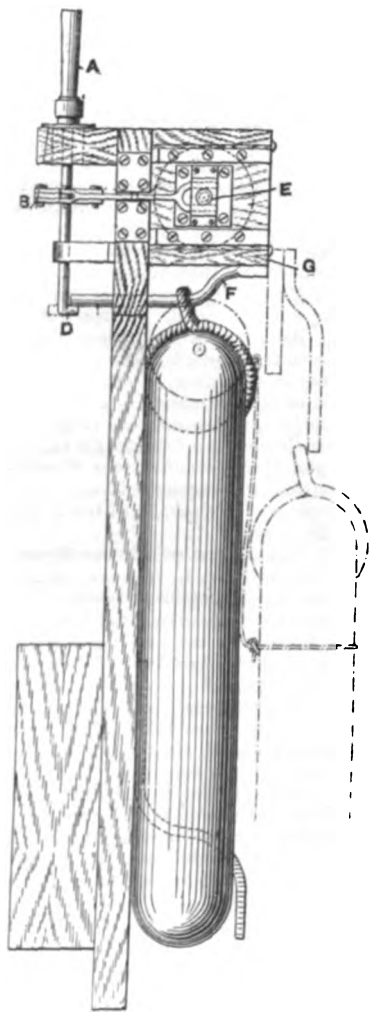

Fig. 1.—End Elevation.

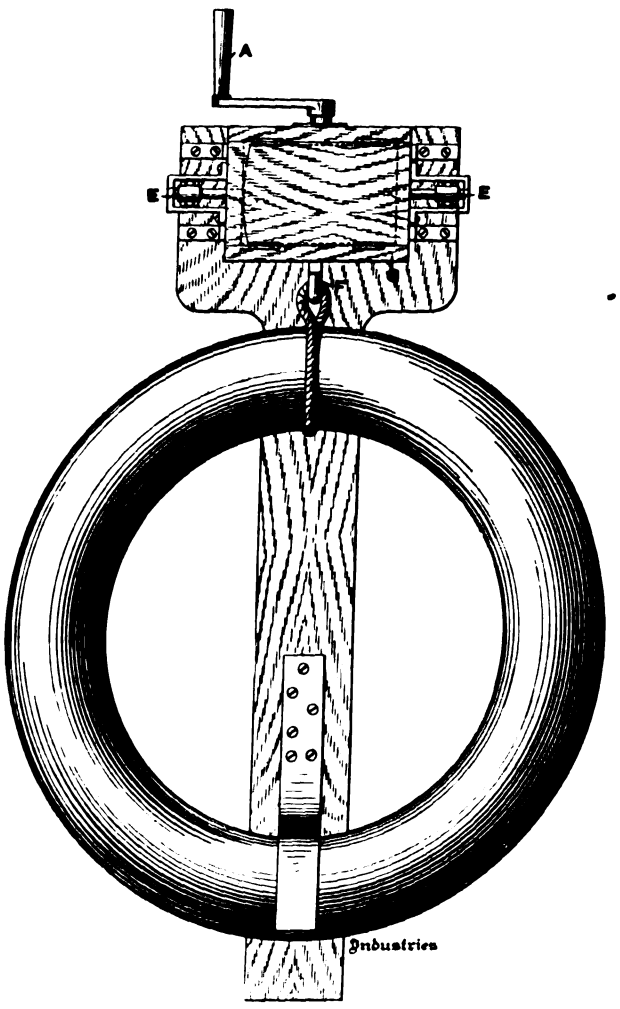

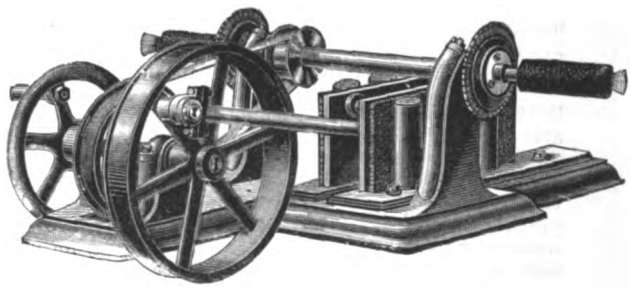

Fig. 2.—Front Elevation.

LAMP CLEANING MACHINE.

The "Presto Economic" lamp cleaning machine, as it is termed by the inventor, Mr. Bartholomew, of the Wombwell Main Colliery, near Barnsley, is a novel contrivance for cleaning the gauze and other parts of miners' safety lamps. Hitherto all machines have been constructed with circular rotating brushes, which require a considerable speed to render them effective. In this machine the inventor has given also a reciprocating motion to the brush.

The machine is driven by means of a belt pulley. On this pulley is secured a crank pin, which carries one end of a connecting rod; at the other end of the rod is

secured two reciprotating brushes for cleaning the gauze. On the same shaft is keyed another pulley which transmits the motion to another shaft carrying the revolving brushes for cleaning the ends of gauze and various other parts of the lamps. By means of this combination of reciprocating and rotary motions, the speed of the brushes is much reduced and the cleaning can be effected with much less trouble. We are informed that at the Wombwell Collieries the saving in the labour of cleaning has been very much reduced. The makers of this machine are Messrs. C. E. Hall, Robinson, & Co., Barnsley.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 17th June, 1890.

Iron.—The downward tendency of prices has become more distinctly marked. The demand, already slack, continues to fall off, and prices are steadily giving way. Here in Paris bars and joists are offered at 152s.; but 150s. is the highest price paid on orders of any importance. Old rails are neglected at 84s. The provincial markets are characterised by the same features, a slack demand and drooping prices. The reductions in the prices of Belgian iron announced the other day have influenced the French markets unfavourably. Consumers are encouraged to wait for the easier terms which they now regard as certain.

Coal.—The probable prices of coal in the second half of the current year continues to be a subject of absorbing interest in the industrial world. At a time when prices are falling in the foreign markets, and the consumption in France is being restricted by shrinkage in the iron trade, the colliery owners are seeking to force up their rates still higher. In the last week some advances have taken place in the North. To make matters worse, the colliers of the Saint Etienne district have interrupted the production in that locality by coming out on strike. The consequence must be to obstruct the current of trade very seriously, not only in iron, but in all the manufacturing industries.

Metals.—The copper speculation has succeeded beyond the expectations of the most sanguine. Prices continue to advance in spite of the fact that consumers limit their purchases to the bare needs of the moment, refusing to believe the statistics which are being published to show that stocks are constantly decreasing. Tin and lead are firm, in sympathy with copper, it must be said, for there is an abundance of both metals in the market. Spelter, though rising in most of the European markets, is weaker here, a point having been lost in the course of the last week.

BERLIN, 16th June, 1890.

Iron.—The iron market of the Upper Silesian district successfully resists the weakening influences arising from the depressed state of things in the West. Buyers operate somewhat less freely, and prices have been modified a little to satisfy their requirements, but, on the whole, there is not much diminution of activity. The current demand for pig iron is sufficient to absorb the whole of the production. Business in finished iron and steel is a little less active, joists being in slower demand. Wire and wire-nails, too, are less inquired after. A large export business in plates is being done with Roumania and Servia. Some important lots have been sold for Copenhagen. Founders and engineers have plenty to do. Here, in Berlin, the market is firmer, Silesian bars being again quoted as high as 200s. The general opinion, however, is that such prices cannot be long maintained. The machinery market is active. The exports of machinery, exclusive of locomotives, portable engines, boilers, and sewing machines, in the first four months of the year amounted to 21,658 tons, against 20,783 tons in the corresponding period of 1889.

Metals.—The metal market, though consumers buy only sufficient for present needs, continues to be characterised by an upward tendency in prices. As there is nothing in the relations of supply and demand to justify this state of things, the movement must be attributed to speculative operations. Mansfeld refined copper has risen to £64 to £66; English brands to £62 and £65 a ton. Tin is a little weaker, Banca being quoted £105. Lead is very firm. Spelter rises slowly, but continuously. Silesian W.H. brand is quoted £24 at Breslau and £26 in Berlin.

The Labour Movement.—The labour movement continues without much abatement all over the country, the consequence being a general increase in the cost of production. The latest development here is a strike of mechanics to obtain a nine hours day and a minimum of 21s. a week wages. Some sixty-two firms, employing about 900 hands, have conceded the men's demands.

Shipbuilding in 1889.—The statistics of shipbuilding in 1889, just published in a complete form, show remarkable activity in all the yards. In the previous year the total number of iron and steel ships built on German stocks, or abroad on German account, amounted to forty-three, of an aggregate tonnage registered as 56,541; last year the number was 101, registering 197,804 tons. Of this number fifty-six were built in Germany and forty-five abroad. Of those built in Germany three were for foreign owners. The estimates for steamers were 15 per cent. higher at the end of the year than at the beginning.

Smokeless Powder.—In some comparative experiments with the smokeless powder C/89, fired from cannon of various calibres, which took place on the shooting ground connected with the Grusonwerk, Buckau, near Magdeburg, it was proved that the new powder yielded an effect from three to four times greater per kilog. of the charge than the old sorts of powder. The powder C/89 threw off a thin brownish vapour, which was so thin that another shot could immediately be fired, the butt being distinctly visible. Even in rainy weather the vapour was completely dissipated within three seconds, whilst the smoke resulting from black powder hung about the gun for a long time, making a quick firing impossible. The powder C/89 leaves so little residuum after combustion that the bore remains almost clean, and the heating of the barrel and cartridge holder is much less than with black powder.

The Trade of Hamburg.—The improvement in the situation of the Hamburg shipowners may be seen from the newly issued report of the Hamburg Shipowners' Association. It appears that the shipping increased by 12,868 tons register in sailing vessels and 109,676 tons gross in steamers. According to the report the Hamburg mercantile marine numbers 290 sailing vessels and 316 steamers, 42 of the latter having been built in the course of the year; at least an equal number is at present on order or under construction. The shipping traffic of the port has also much increased. A total number of 8,059 vessels of 4,809,892 tons register entered, compared with 7,524 vessels with 4,345,000 tons register in the previous year. It is thought that 5,000,000 tons may be exceeded this year. The superiority of English shipowners is still maintained. They contributed 45·7 per cent. of the total shipping, whilst Hamburg itself could only show 36·6 per cent. With the increase in the traffic the extension of our docks has become the object of animated discussion. Recently, also, the question of the formation of a dock at Cuxhaven adapted for the large fast steamers has come to the front.

The Valves of Compound Locomotives.—In a recent article in the *Organ des Eisenbahnwesens*, Herr Von Borries says that the valves of compound locomotives should be composed of 82 parts of copper, 14 of tin, 2 of zinc, and 2 of antimony. He further states that a compound engine of the old Woolf tandem type, which was tested in France, gave a saving of 12 per cent. in fuel and an increased efficiency over similar simple types.

Novel Air Brakes.—Not the least interesting feature of the Jungfrau Railway is the plan for keeping the speed of the cars within prescribed limits during the descent. Folding doors will be placed along the tunnel at short intervals, and will be kept closed except during the passage of a car. The cars have movable wings which may be expanded by the guard until they nearly touch the tunnel lining. In this way the car becomes a kind of piston working in the tunnel as a cylinder, and the air acts as an automatic brake just as in the well-known dash-pots of Corliss engines. As the cars are also provided with several brakes of the usual types, it would seem as if the tourist need have little fear of such accidents as usually occur on inclined railways.

VIENNA, 16th June, 1890.

The Iron Market.—The situation of the iron market is very firm. Every attempt to cut down the prices is futile. Notwithstanding the lateness of the season there is a good demand for building materials. In Hungary the prospects of a good harvest have an excellent influence on the iron market, and the works are receiving important orders. There is a good sale for agricultural machines. No doubt the Agricultural Exhibition is to be thanked for this. The prices of iron may be quoted as follow:—Bar iron, 135fl. per ton; for girders, 130fl. per ton; boiler-plates, 200fl.; and tinned sheets, 275fl.

The Coal Market.—Animation continues throughout the coal market. The strike in the Pilsen district has terminated, but as many of the shafts are inundated it is not possible for labour to be completely resumed for some weeks.

A Vienna Central Railway.—A proposal is now afloat for constructing an underground railway in Vienna. The cost is estimated at 16 million gulden. The locomotives will be of the usual type, but will be adapted for burning coke instead of coal, so as to reduce the amount of smoke given off, and the carriages are to be built on the Pullman system. There seems to be every probability of the scheme being a success.

Beer.—In nineteen countries the sum of 173,662,717fl. was yielded last year by taxes on the production of beer. The total beer production was 236,319,397 hectolitres, of which 231,701,652 hectolitres were taxed. Comparing the latter quantity with the yield of the brewing tax, it is seen that each hectolitre of beer pays on an average 1·34fl. Whilst in the German Beer Excise District the tax per hectolitre is only 47 kreuzers, in Austria it is 2·18fl. With the exception of a few unimportant countries, Austria can boast of having the highest tax on beer. In Austria-Hungary, in 1889, there were 1,952 breweries at work, in which 13,728,431 hectolitres of beer were brewed (as compared with 13,184,026 hectolitres in the preceding year). The revenue accruing therefrom to the State was 25,325,252fl. (24,358,773fl. in 1888). The malt used amounted to 3,549,564 centners, and the hops to 102,800 centners only. In the German Empire in 1889 there were 25,434 breweries at work, and their total production was 47,602,939 hectolitres of beer (1888, 26,240 breweries, 47,243,706 hectolitres production).

BRUSSELS, 17th June, 1890.

Iron.—As the home demand for iron does not improve, and as moreover competition in foreign markets becomes every day more difficult, the syndicate of iron manufacturers has found itself compelled to make another reduction in prices. The rates now are—for merchant bars 116s., and for plates 140s. a ton, with 8s. a ton difference for each class. This makes 124s. for No. 2 bars. There are good grounds for believing that these reductions will bring a large accession of business, for buyers have been keeping back their orders in expectation of the event, and the changes have put our manufacturers in much more favourable circumstances relatively to the foreign markets. It is to be regretted that the new rates are not remunerative. The margin for profit will have to be obtained by reductions in the cost of coal. Founders generally are busy, and engineers report specifications coming to hand more freely. There is no change to note in the pig iron market. As prices are very irregular it is useless to give quotations.

Coal.—The situation is gradually changing in favour of buyers. As contracts run out they are not renewed, consumers contenting themselves with buying for present needs. This restriction of business is beginning to show itself in accumulations of stock about the pits. The weakening tendency of the market has been checked by the colliers' strikes in France, but it is generally believed that lower prices will soon be announced. The constantly drooping prices of iron show the impossibility of the manufacturers paying the present rates for coal. Though the demand is falling off there is still great activity in the trade. The number of coal waggons despatched over the State railways in the week ending with the 8th inst. amounted to 59,753 against 57,805 in the corresponding week of last year. The average for the twenty-three first weeks was 57,200 in 1890, against 54,929 in 1889 and 53,031 in 1888.

Glass.—The slight changes that have occurred in the last two or three weeks in the glass making industry have brought no relief to the manufacturers. The lower prices for coal are compensated by a rising tendency in wages. The demand continues slack, and there is no prospect of immediate improvement. The share market shows this in the weaker tone that prevails, the upward movement in glass securities having come to an end.

DÜSSELDORF, 17th June, 1890.

Iron.—The iron market continues lifeless. The anticipations of consumers have been in part realised, for at the general meeting of the blast furnace owners, held on the 10th inst. at Cologne, considerable reductions were made in the prices of pig iron. The minimum rates now are:—Ordinary spiegel, 93s.; best Rhenish-Westphalian forge, 72s.; foundry No. 1, 78s.; Bessemer, 78s.; and Thomas, 60s. a ton. These reductions will lead, probably, to some buying, because the consumers have been keeping back their orders for this opportunity. The market for finished iron and steel is very quiet, and the near prospect is discouraging. Were it not for the syndicate combination which exists, prices would fall heavily. Now that pig iron is cheaper some reduction may be expected at the next meeting of the manufacturers. In anticipation of this the merchants are offering iron 5s. a ton below the syndicate minimum. For joists there is still a fairly brisk demand, but all other classes of finished iron and steel are neglected. The calm is, however, in part—some believe for the most part—due to the withholding of orders in expectation of better terms.

Coal.—Business in the coal market continues slack. Buyers are playing a waiting game; but the situation is such that sellers can afford to look on with indifference. There can be hardly any accumulations of stocks to begin the winter with. The colliery owners have made large reductions in prices, and they have probably descended to the lowest level which this year is likely to bring. The Gas Coal Owners' Association have fixed their price at 12s. a ton. At the end of April the quotation was 13s. 6d. to 15s. The statistics of coal production in the month of May show, relatively to the same month of last year, the following changes:—In the Saar district, 405,190 tons, against 420,810 tons; in the Wurm district, in the neighbourhood of Aix-la-Chapelle, 110,840 tons, against 91,370 tons; in the Upper Silesian district, 864,710 tons, against 751,700 tons; and in the Ruhr district, 2,499,860 tons, against 1,288,580 tons. The great difference in the latter district is due to the general strike which took place in May of 1889.

The Art of Printing.—The four hundred and fiftieth anniversary of the invention of the art of printing is to be celebrated at Mayence, the cradle of the art, in a simple and worthy manner. An exhibition of old printing work will be opened in the Academical Hall of the Electoral Castle on the 22nd of June. A meeting will be held in connection in the town hall, when the municipal band and cathedral choir will render a musical selection, and Dr. Nelke, the curator of the museum, will deliver an address. A *fête* will take place in the Gutenbergsplatz on St. John's Day.

The Gunpowder Trade—A new share company has been registered, with a capital of 16½ million marks (£825,000), to absorb the United Rhenish-Westphalian Gunpowder Company and the Rottweil and Hamburg Gunpowder Company. The general management will be entrusted to Herr Heidemann. The new company is to be known as the Cologne and Rottweil Gunpowder Manufacturing Company. This fusion is a matter of considerable importance to the gunpowder trade, inasmuch as it is tantamount to the formation of a "ring."

The Frankfort Exhibition.—The Oerlikon Works, and Messrs. Escher, Wyss, & Co., of Zurich, propose to run electrical boats on the Maine. The Electro-Technical Society of Frankfort is organising a conference on technical subjects connected with their branch of science.

Digitized by Google

LILLE, 17th June, 1890.

Iron.—Business is very slack in the iron market, and prices continue their downward course. Merchant bars are still quoted 144s., and common plates 176s. a ton, but large concessions are made on these prices. It would be difficult to say what the current prices of bars are. The Paris merchants are, it is said, offering 128s. for bars. This price is refused, it is true; but the fact of its being offered shows how the Paris merchants regard the future. In the face of all this the coal owners maintain their prices firmly. The situation is thus becoming greatly strained.

Textile Manufactures.—The linen goods trade has revived a little within the last few days, the volume of business transacted in the course of the week being considerably larger than that of the previous week. No change has taken place in prices. The continued rise in the prices of yarns is beginning to cause uneasiness on account of the difficulty of obtaining higher prices for woven goods. There are yet no signs of revival in the woollen goods trade of the Roubaix district. Manufacturers who, a few weeks ago, were very hopeful concerning the coming season, now regard the near future despondingly.

Flax and Yarns.—The market is very active for home-grown flax, and prices are steadily rising. A brisk business, too, is being done in Russian at firm prices. There is not much doing in tows; the better qualities are scarce. Yarns are in strong demand, and spinners have profited by it to further advance their prices. The higher rates are readily paid. The market is animated for jute yarns, the prices of which are decidedly in favour of sellers.

AMSTERDAM, 16th June, 1890.

Telegraphs in the Dutch West Indies.—The Dutch Government has impounded the guarantee, or caution money, deposited by the Pedro Segundo Telegraph Cable Company, of New York, which has failed to carry out its contract for the laying of a cable connecting Paramaribo, the capital of Surinam, with Cuba and Florida, *viâ* Curaçoa. The same contract, or a similar one, has now been undertaken by the Compagnie Française des Télégraphes Sous-marins, in Paris, against a Government subsidy of £2,000 per annum, which amount has, consequently, been made a budget proposal.

Ancient Dutch Compound Engines on Steamers.—Mr. N. Th. Michaelis, the President of the Royal Institute of Civil Engineers, has drawn public attention to the fact that the most ancient compound engines on steamers were probably constructed at Fyenoord, near Rotterdam. They were made there as early as 1829, when the steamer "Hercules" was launched from the establishment of Mr. C. Röntgen, having then a compound engine in her. Mr. Michaelis has received a letter from the French engineer, M. Mallet, who states therein, that to his knowledge eighteen ships had been fitted with compound engines at Fyenoord before the year 1843.

New Line of Steamers from Holland to South America.—The success of the Netherland-American Steamboat Company, in opening a new line of steamers to the Argentine Republic, has prompted the directors of the Royal Mail Steam Packet Company to start a line of ocean steamers from Rotterdam to Buenos Ayres and Montevideo. This new service will commence in September next. In the journey out, the vessels, after leaving Rotterdam every month, will call at London, Southampton, Corunna, Vigo, Cadiz, and Los Palmas, and will also call at some of these ports on the return journey, with the addition of Santos, Rio de Janeiro, and Lisbon.

COPENHAGEN, 14th June, 1890.

The Danish Engineering Society.—This society held its annual meeting the other day, Professor Holmberg in the chair. The President read the Society's report. The number of members had now reached 589. During the past year eight meetings had been held and eleven papers read. The members had visited several industrial establishments. The prize competition for 1889 was on "The use of animal offal, and industrial establishments for utilising it." Four answers were received, but not one was considered satisfactory, so the prize of 500kr. was not awarded. The following prize competition was decided upon for the present year:—"What should be the sanitary requirements for dwellings of the poor, especially where such dwellings have to be in large numbers in high buildings?"

Stockholm Gasworks.—The gasworks in Stockholm belonged, up to the year 1884, to a private company, but passed then into the possession of the corporation. Both the company and the town have made a very good thing out of the gasworks, and last year's profits compare favourably with those of previous years. The gross profits on the gasworks have, with the exception of one year, been steadily increasing since they have been in the hands of the corporation, as will be seen from the subjoined figures:—

1885	977,910kr.
1886	962,318kr.
1887	1,076,185kr.
1888	1,165,987kr.
1889	1,325,638kr.

The production of gas during last year amounted to 10,960,460 cubic metres, which is an increase of about 4¼ per cent. as compared with the previous year. The consumption of gas for public lighting has increased by 3 per cent., the private consumption for lighting about 2¼ per cent., and the consumption for cooking, heating, and motive power, 45·3 per cent.

Beet Sugar Manufacture in Sweden.—The manufacture of beet sugar in Sweden has become a very important one during the last few years, and the erection of one or two other works has been under contemplation. The Lund sugar manufactory has, from September 30th, 1889, to February 24th this year, handled 39,000,000 kilogrammes of beet root, and the cost of labour and raw material amounted to 1,357,000kr. The result was a very satisfactory one, the net profits amounting to between 300,000kr. and 400,000kr. A dividend of 15kr. per share was declared.

MADRID, 16th June, 1890.

Peral's Submarine Torpedo Boat.—There was a great deal of enthusiasm about the trials of the Peral submarine boat during the past week. The trials are considered to indicate the greatest possible success in submarine navigation. The boat travelled at a depth of 10 metres for one hour and five minutes following the course ordered by the admiral directing the trials. The boat was able to go down and to come up at any rate, and moved without any risk of overturning. Subsequently she discharged a torpedo without its being seen. All the naval authorities express great satisfaction.

Two Steamers Lost.—The merchant steamer "Cabo de Gata," belonging to a Seville company, and the "Manuela," owned by a Bilbao house, were wrecked on the same day. Both will be replaced at once by purchases to be made in England. It is likely that the ship that will replace the "Cabo de Gata" will be the last to be bought in England, as the building yard at Bilbao will in future attend to the wants of most of the Spanish companies. The building of the first merchant vessel at Bilbao is expected to begin next September.

Telephonic Concessions.—By a recent royal decree the Minister of the Colonies has been authorised to make concessions for telephonic services in the islands of Cuba and Porto Rico and the Philippine Isles.

NEW YORK, 7th June, 1890.

Shortening the Erie Railway.—Some time since extensive surveys were made between Forest City and Hovesdale for the purpose of shortening the route from Buffalo to New York. These surveys were for a route to connect the Carbondale and Hovesdale branches of the Erie railway, making them the main line and discarding the Deposit Hill branch, thus lessening the distance fifty miles. The surveys resulted in two schemes, one to tunnel the mountains for a distance of thirteen miles, which would involve an expense of $2,000,000, and another to adopt a less direct overland route through the valley at a cost of $1,500,000. The necessary capital has been secured, and at a meeting of the directors of the proposed short cut it was decided to adopt the tunnel route.

Government Vessels.—The gunboat "Bennington" was launched at Roach's shipyard, Chester, on the 3rd inst. She is a sister ship of the "Concord," launched a few months ago. Her dimensions are: Length, 230ft.; extreme breadth, 36ft.; displacement, 1,700 tons. Two triple-expansion engines, developing 2,200 h.p. with natural draught and 3,300 h.p. with forced draught, will supply the motive power. The cylinders are 29in., 31in., and 50in. diameter by 30in. stroke. Her armament will consist of six 6in. breechloading rifles and a secondary battery of eight rapid-firing guns and revolving cannon on rail and tripod mounts; also eight torpedo guns with complete outfit. The "Vesuvius" has been handed over to the Government, and has gone into commission. She is complete except as to electric light plant and rapid-firing guns.

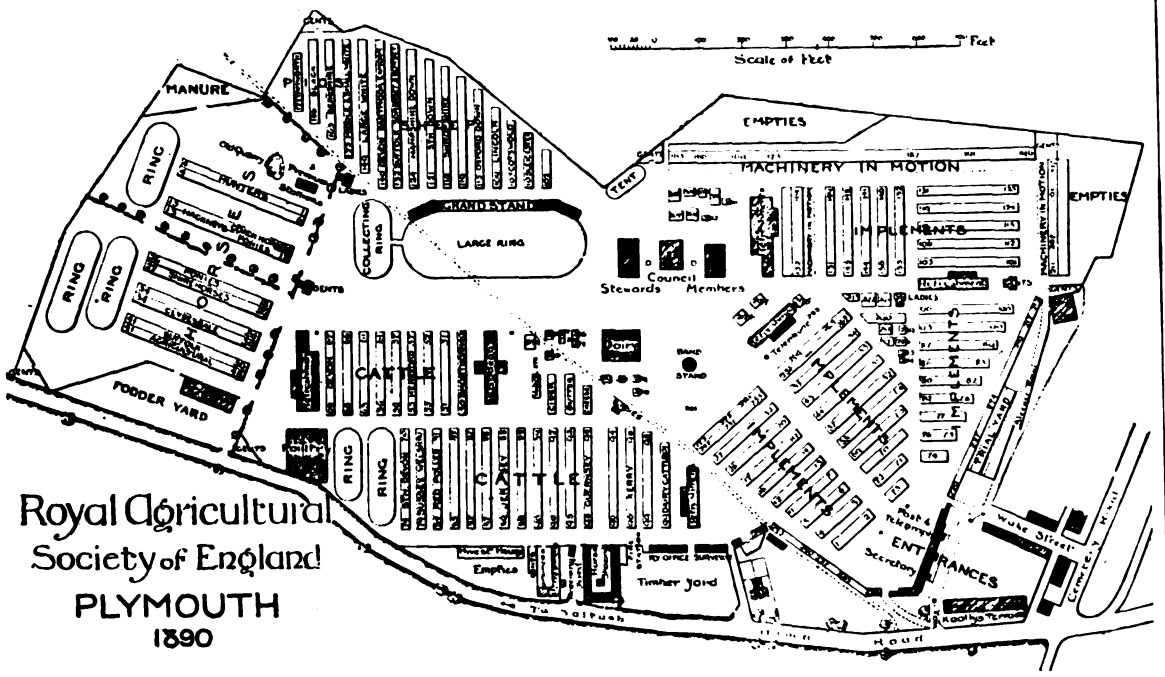
Pan-American Plans.—On the 2nd inst. the President sent to Congress a letter from the Secretary of State, relative to the recommendations of the recent Pan-American Conference on the subject of Customs regulations. The President, in transmitting the letter, stated that the Conference recommended for adoption: uniform Customs regulations for the classification and valuation of imported merchandise; a uniform nomenclature for description of articles of merchandise imported and exported; and the establishment at Washington of an International Bureau of Information. The Conference also decided to establish at Washington, as a fitting memorial of its meeting, a Latin American Library, to be formed by contributions from the several nations, of historical, geographical, and literary works, maps, manuscripts, and official documents relating to the history and civilisation of America, and expressed a desire that the Government of the United States should provide a suitable building for the shelter of such a library, to be dedicated upon the four hundredth anniversary of the discovery of America. Secretary Blaine recommends that Congress appropriate $250,000 to provide a building to receive the proposed collection, which building may also be used for the offices of the proposed Bureau of Information.

The Justin Gun.—The attempt to fire dynamite from an ordinary gun, as tried by Dr. Justin near Perryville, New York, came to a sudden termination by the total collapse of the gun. Two previous trials had been made which were so satisfactory that there was little doubt as to the success of this trial. The gun was an ordinary 9in. Blakely rifle. The shell was 44in. long of half-inch steel, and weighed 289lb. It contained 16½lb. of dynamite. The powder charge was 30lb. of ¾ prismatic powder, which was fired by a slow burning fuse. The explosion scattered the pieces of the gun around the neighbourhood. It is believed that the walls of the shell were too thin, wedging it in the barrel, and causing the explosion to take place in the barrel itself. A flaw was found in the breech of the gun, but the result would probably have been the same if the gun had been perfect. It is probable that Dr. Justin will continue his experiments, as his financial backers have faith in his success.

The Chicago Exhibition.—The Chicago Fair site question seems to be practically settled in favour of the central lake front site, 253 acres of which has to be filled in. The most serious objection is that it will crowd the down-town streets excessively, the tide of travel corresponding with the regular business travel. About 8,500,000 cubic yards of filling will be required, which can most cheaply be obtained by dredging.

PHILADELPHIA, 6th June, 1890.

The Pennsylvania Railway Company.—The annual report of the Board of Directors of the Pennsylvania Company, presented at the meeting held on the 3rd inst., covers the operations of 2,870 miles of road. The total revenue derived from the net earnings of the Union line, rent of real estate and equipment, profit in operating leased roads, and dividends and interest on securities owned amounted to $2,610,577·82. Deducting expenses, interest on car trusts' bonds, and losses in operating certain leased roads, in all amounting to $1,882,775·60, there is a profit for the year 1889 of $727,802·22, against a loss of $74,890·63 for the year 1888. On the Pittsburgh, Fort Wayne, and Chicago Railway, there was a profit in operating of $756,811·75, against a loss for the same time in 1888 of $371,851·28. On the Erie and Pittsburgh road there was a loss of $290,734·42, an increased loss of $107,572·15 as compared with last year. On the Indianapolis and Vandalia road there was a loss of $155,436·42, a decreased loss of $18,353·69 as compared with last year. The tonnage on the North-Western system, exclusive of the Grand Rapids and Indiana Line, shows an increase of 2,944,034 tons, or over 17 per cent. The Pennsylvania Railroad has a force of 3,000 men at work on what is known as the Downingtown cut off, and it is intended to finish the line within six months. This road will run from Downington on the main line to Morrisville on the New York division, and when ready for use no through freight will come to Philadelphia, and fast passenger trains will also use it to make better time from New York to the West. Much of the work is very heavy, but it is being rapidly pushed on. A feature of the construction is that the curves on this new line are so arranged as to keep the entire range of sight open and clear to the driver.



Railroad Consolidation.—Three important railroad meetings have been held in Philadelphia during the last few days—viz., the Chicago, St. Louis and Pittsburgh, the Pittsburgh, Cincinnati, and St. Louis, and the Pennsylvania Company. A plan for the consolidation of four Western lines, now controlled by the Pennsylvania Company, was submitted to the directors of the first two companies, and was agreed to by them. The plan is substantially as follows:—The first two companies, the Cincinnati and Richmond, and the Jeffersonville, Madison, and Indianapolis Company, are to be consolidated into one company. The capital stock of the new company will be $75,000,000, of which $45,000,000 will be common and the balance preferred stock. An equal amount of bonds will be issued. These issues will take the place of the stocks and bonds of the present companies. It is estimated that 40 million of stocks and bonds will be required for present use, the balance to be reserved for future improvements. After the plan has been presented to the directors of the last-named companies the stockholders of the four companies will meet and take action upon it.

Another Shipyard.—The rumour which has been current for the past two or three years, that a shipyard syndicate was to start a large shipbuilding establishment on the Delaware, has been revived, and it is said that sixty acres of land lying between the Pennsylvania Salt Works and Mifflin Street has been purchased for the purpose. The land is owned by Mr. Walton Ferguson, of New York, and no transfer has yet been recorded. A prominent shipbuilder says that there have been various syndicates formed within the past few years with a view of starting such a yard. These syndicates have all had considerable money at their back, but have never been able to accomplish anything.

A Large Testing Machine.—A testing machine, just completed by the Phœnix Iron Company, of Phœnixville, Pa., is said to be the largest ever built. It is designed to test full-size bridge members up to 55ft. in length, and with loads up to 2,000,000lb. either in tension or compression. Water pressure of 720lb. per square inch is applied to a cylinder 5ft. 6in. in diameter and 5ft. stroke. The general style of construction is similar to the machine at the Union Bridge Works at Athens, Pa. The cylinder is of cast steel, and without the heads weighs 28,000lb.; the other parts, cross-heads, &c., are correspondingly massive. All castings were made by the Chester Steel Co., of Chester, Pa., while the rest of the work was done in the shops of the Phœnix Co.

THE ROYAL AGRICULTURAL SHOW.

PLAN OF SHOW YARD.

CLYDE SHIPBUILDING IN MAY.

SCARCELY any improvement has taken place in the demand for new tonnage, and the orders booked by Clyde shipbuilders during May were few in number, the aggregate tonnage being not more than 6,500 tons. The most important contract was arranged with Messrs. A. Stephen & Sons, Linthouse, by Mr. J. Bruce Murray, Glasgow, for a vessel of 2,700 tons, having a deadweight capability of 4,300 tons, and intended for general trading purposes. The other contracts include a screw steamer of 1,700 tons, to be built by the Campbeltown Shipbuilding Company; a sailing vessel to be built by a Port Glasgow firm; and a passenger steamer for service on the Nile, to be built by Messrs. J. McArthur & Co., Paisley. As in previous months during the year, the new work contracted for was largely exceeded in point of tonnage by the output, which reaches the respectable total of 25,974 tons. The work in hand is decreasing at a very rapid rate, and unless the flow of orders for new vessels becomes brisker than it has been for the past five months, quite a number of firms will shortly have little or nothing to do. The prices of material have a downward tendency, and although there is a disposition on the part of some builders to lower the standard of prices for work, labour still maintains itself at high rates. The trials of the two new paddle steamers, 'Marchioness of Breadalbane" and "Duchess of Hamilton," built for the passenger traffic of the Caledonian Steam Packet Company, took place during the month. The former vessel, which was constructed by Messrs. G. Reid & Co., Port Glasgow, is 200ft. long by 22ft. beam, by 7ft. 9in. depth, and on her trial attained a speed of 17 knots. The latter vessel, was built in Dumbarton by Messrs. William Denny & Brothers; she is 250ft. in length, 30ft. in breadth, and 10ft. 6in. in depth, and on trial proved herself to be the fastest paddle steamer on the Clyde, her average speed being 18·1 knots.

The following are the particulars of the vessels launched during the month:—

SINGLE SCREW STEAMERS.

"Alcestis," steel, 1,850 tons, built by Messrs. Mackie & Thomson, Govan, and fitted with triple-expansion engines by Messrs. Muir & Houston, Glasgow, for the general trade of Messrs. Aitken & Walker, Glasgow.

"Bosnian," steel, 348 tons, 450 i.h.p, built by Messrs. Mackie & Thomson, Govan, and fitted with triple-expansion engines by Messrs. Muir & Houston, to the order of Messrs. G. McFarlane & Co., Glasgow, for the Irish fish trade.

Dredger (hopper), steel, 400 tons, 300 i.h.p., built and engined by Messrs. W. Simons & Co., for dredging operations in Japan.

"Dunottar Castle," steel, 5,000 tons, built and supplied with triple-expansion engines by the Fairfield Shipbuilding and Engineering Company, Govan, for Messrs. Donald Currie & Co., for their service between Britain and South Africa.

"Finnieston," steel, elevating ferry, 250 tons, built and engined by Messrs. W. Simons & Co., Renfrew, for the cross river traffic of the Clyde Navigation Trust.

"Gannet," steel, 280 tons, built by Messrs. David Macgill & Co., Irvine, and engined by Messrs. Wm. Kemp, Govan, for the Glasgow and Greenock Shipping Company.

"Grimini," steel, 2,800 tons, built by Messrs. Charles Connell & Co., Scotstoun, and fitted with triple-expansion engines by Messrs. J. & G. Thomson, Glasgow, to the order of the Dampfschiff-Rhederei Hansa, Hamburg.

"Kallatina," steel, 500 tons, built and engined by Messrs. D. J. Dunlop & Co., Port Glasgow, for the Clarence, Richmond, and Macleay Rivers Steam Navigation Company, Sydney, N.S.W.

"Strathallan," steel, 2,340 tons, built by Messrs. Russell & Co., Greenock, and fitted with triple-expansion engines by Messrs. J. Howden & Co., Glasgow, for the general trade of Messrs. Birrell & Sons, Glasgow.

"Talbot," steel, 550 tons, built by Messrs. M'Knight & Co., Ayr, and fitted with triple-expansion engines by Messrs. Muir & Houston, Glasgow, and intended for the Liverpool, Swansea, and Port Talbot trade of Messrs. John Bacon & Co., Liverpool.

"Taviuni," steel, 1,500 tons, built by Messrs. William Denny & Bros., Dumbarton, and fitted with triple-expansion engines by Messrs. Denny & Co., for the Fiji trade of the Union Steamship Company, New Zealand.

"Teucer," steel, 2,800 tons, 1,500 i.h.p., built and fitted with compound tandem engines by Messrs. Scott & Co., Greenock, for the Ocean Steamship Company, Liverpool, for their China trade.

"Vitæ," steel, 900 tons, built by the Ailsa Shipbuilding Company, Troon, and fitted with triple-expansion engines by Messrs. Dunsmuir & Jackson, Govan, for the British India Steam Navigation Company, London.

TWIN SCREW STEAMER.

"Clutha" No. 7, steel, 30 tons, built by Messrs. Murray Brothers, Dumbarton, and engined by Messrs. Matthew Paul & Co., Dumbarton, for the passenger traffic of the Clyde Navigation Trust.

PADDLE STEAMERS.

"Hygeia," steel, 800 tons, built by Messrs. Napier, Shanks, & Bell, Yoker, to the order of Messrs. Huddart, Parker, & Co., for their passenger service in Australian waters.

"Mana," tug, 240 tons, built and engined by Messrs. Fleming & Ferguson, Paisley, for the Timaru Harbour Board, New Zealand.

"Marchioness of Bute," steel, 250 tons, built by Messrs. J. Reid & Co., Port Glasgow, and fitted with compound engines by Messrs. Rankin & Blackmore, Greenock, for the passenger traffic of the Caledonian Steam Packet Company.

SAILING VESSELS.

"Airdnamurchan," steel, 1,700 tons, built by Messrs. Russell & Co., Port Glasgow, to the order of Mr. H. Hogarth, Glasgow.

"Barcraig," steel, 2,100 tons, built by Messrs. W. Hamilton, Port Glasgow, for the general trade of Messrs. Hamilton & Harvey, Glasgow.

"Mirfield," steel, 1,320 tons, built by Messrs. Russell & Co., Port Glasgow, to the order of Messrs. Alexander Rae & Co.

YACHTS.

"Encore," 10 tons, built by Messrs. W. Fife & Sons, Fairlie, for Mr. K. H. Clark, Paisley.

"Nan," 6 tons, built by Messrs. Fife & Sons, for Mr. T. Burrows, Lismore, Ireland.

"Phantom," 10 tons, built by Mr. James Adam, Gourock, for Mr. A. Arthur.

"Woodcock," 10 tons, built by Messrs. W. Fife & Sons, Fairlie.

In addition to the above four electric launches were completed by Messrs. T. B. Seath & Co., Rutherglen, for the Electric Traction Company, and intended for use at the Edinburgh Exhibition.

THE ROYAL AGRICULTURAL SHOW.

THE annual Show of the Royal Agricultural Society will be held at Plymouth from Saturday, the 21st inst., to Friday, the 27th inst., inclusive. On the first day only the implement department will be on exhibition, and the show of live stock will be open on Monday, the 23rd. On Tuesday, at 12.30, a general meeting of the members will be held. Various competitions will be held during the week, such as horse shoeing, butter making, &c., and lectures and demonstrations in bee keeping, dairy work, jam making, &c., will take place at intervals. The yard is being protected from fire by one of Messrs. Shand, Mason, & Co.'s steam fire engines. The accompanying plan of the yard may be of use to our readers; we are indebted to the Society for permission to reproduce it from their official catalogue.

THE "HASELEY TEDDER."

WE illustrate below a tedder which is made by Mr. J. V. Gibbons, Haseley Ironworks, near Tetsworth, Oxon. In it a row of hay-forks is actuated by cranks, so as to give a motion similar to manual hay tedding.

Each fork is fitted with four of Gibbons' coiled spring teeth, which have great flexibility. All the working parts can be thrown out of gear when travelling.

THE TOWER BRIDGE.

THE erection of the steel superstructure of the Tower Bridge may now be said to have been commenced in earnest. For the last six months preparations have been made at the site, that all might be ready to build the bridge by the time the lower portion of the work has been constructed at Messrs. William Arrol & Co.'s Works at Glasgow, where there is now a large quantity of the steelwork finished.

As many of our readers are aware, the bridge will consist of one central opening of 200ft. clear, and two side openings each of 270ft. clear. Upon each of the two massive masonry piers—which are already built in the river—and also on each of the abutments, will be placed four steel octagonal columns, those on the piers reaching to a height of 135ft., and those on the abutments 66ft., above high water. These columns will carry steel chains, from which the roadway of the side spans is suspended. For the purposes of the river traffic the central span is capable of being opened, the steelwork being so designed as to admit of each half rotating in a vertical plane through an angle of 90 deg. In order not to prevent pedestrian traffic while the bridge is thus open, an overhead footway is provided at a level of 135ft. above high water, at each end of which hydraulic lifts will be provided.

Two temporary timber piers have been driven in the side opening next to the Middlesex shore, and upon these girders have been placed, to form a stage some 70ft. wide, upon which the steelwork of this span will be built. This stage appears now to be practically complete. The side opening on the Surrey shore of the

Digitized by Google

river will be similarly staged over, one of the temporary timber piers being finished and the other in the course of construction. Considerable care and labour has evidently been expended in forming these timber piers. The traffic at this part of the river is so great that the driving of the piles alone must have given a good deal of trouble; and when it is considered how liable they are to collision from the many large steamboats that unload near the site, to say nothing of the numberless barges that crowd the river, and how serious a collision might prove when the steelwork is in the course of erection, it is evidently of primary importance to have such piers as we now see constructed.

Many hundreds of tons of the steelwork have been delivered, and some erected, at the site, and large quantities are being sent on weekly from Glasgow. It is expected that the building of the main columns on the Middlesex pier will be commenced next week.

ROYAL STATISTICAL SOCIETY.

"An Examination of the Coal and Iron Production of the Principal Coal and Iron-Producing Countries of the World, with reference to the English Coal Question," was the title of the paper read by Mr. G. G. Chisholm, M.A., B.Sc., &c., on Tuesday, the 17th inst.

With a view to this examination a comparison is first made of the rates of increase in the amount of coal production in different countries. A table drawn up for this purpose shows that since 1860 the rate of expansion under this head has been less rapid in the United Kingdom than in several other countries, notably the United States and Germany. If the same average rates of expansion were continued indefinitely in the future for the United Kingdom, the United States, and Germany respectively, as are found by calculation to have been maintained for these countries between the mean of the three years 1879–81 and the mean of the three years 1886–88, then the coal production of the United Kingdom would be overtaken by that of the United States in 1894, by that of Germany in 1928, by the aggregate coal and lignite production of Germany in 1919. A similar examination of the rate of growth of the production of iron shows that in this industry these two countries appear to be gaining still more rapidly upon the United Kingdom. This is important as tending to bring about a diminution in the rate of increase in the demand for British coal. Hitherto the iron industry of the chief industrial countries has been greatly stimulated by the rapid extension of railways. An examination of railway statistics since 1840 shows that the new mileage required year by year all over the world has increased on the average at a pretty high geometrical rate. The examination shows also, however, that this is brought about by the construction of railways on a great scale in different parts of the world successively. Regions in which railways have long been laid show no such rapid increase in the amount of the new mileage. This leads to the conclusion that sooner or later a time will come when the rate of increase of the railway mileage of the world will be greatly reduced. That would probably involve a pretty severe check to the growth of the demand for iron, and indirectly that of the demand for coal.

With regard to the consumption of British coal, any conclusions that may be drawn from such data as are dealt with in this paper should be stated with great diffidence: but, so far as yet appears, we have no reason to anticipate at any time anything of the nature of a disaster or sudden catastrophe from our continued consumption of coal. The change of conditions will probably be a gradual one throughout. First we may expect only the continuation of a process already begun, a gradual contraction in the rate of expansion of the coal production. That may pass insensibly into a stationary state of coal production, to be followed by a gradual decline. Such, remarks Professor Marshall, is the actually observed history of the working of individual coal mines. It may be that the modification of the rate of increase or decrease of the amount of coal production will not always be so gradual as it is now: still we may hope that it may be gradual enough to allow of the habits of the people being adapted to the changing conditions. Nevertheless, the fact of the steady rate of increase in the aggregate number of the population of Great Britain, taken along with apparent signs of a declining rate of expansion in some of the chief industries of the country, is one that cannot be regarded with equanimity, and makes it urgently to be desired that the true state of the case should be carefully inquired into, and made as widely known as possible. With reference to the possibility of the influences adverse to the production of British coal being somewhat suddenly and strongly reinforced in the future, an account is given from Richthofen's "China," of certain great Chinese coalfields, the connection of which by rail with the great plain of China and the great seaports could not fail, according to Richthofen, "to bring about a revolution in the commerce and intercourse of the world."

"	English Ingots	100	10	0	"	.....		

Messrs. Carrick & Brockbank, Manchester, report as follows:—

Copper continues firm and strong, with a tendency to still higher values. Prices of raw are steadily advancing, large buying taking place both for consumption and for speculative account, the statistical position inducing speculators to take a keen interest in copper. It is a noticeable feature that a large proportion of the buying is for three months' account, which indicates confidence in the market. Stocks are being very considerably reduced, the visible supply showing a reduction of slightly over 6,000 tons from the 1st to the 15th inst. Chili bar quotations to-day are £59 to £59 10s. cash, with large business. Manufactured is quoted £70 to £72 sheets, £73 to £75 bottoms.

Tin has fluctuated somewhat during the week, and values are lower, the variations in silver having affected prices. A firmer tone, however, is to day observable at improving rates.

Lead: As noted in our last, the market is firmer, and prices have advanced slightly. A fair business has been done during the week, and there is a better demand all round.

Spelter continues very firm, as the metal is scarce, and buyers have to pay full prices. It is likely to advance, as business is improving, and there are no stocks in makers' hands or at the outports.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

Chemicals: Caustic soda has considerably improved during the last week, and prices are tending further upwards. Soda crystals are also firm, and bicarbonate of soda is in short supply for present delivery. Bleaching powder is very dull at lower figures, and soda ash is quiet at rather easier prices. Sulphate of copper is more freely offered for present and July delivery. There is considerable variation in quotations for later delivery, and the steady advance in copper has checked business in that direction. Carbolic acids are again very quiet; there is more crude offering, and makers show more disposition to meet buyers' terms. Tartaric and citric acids are easier, and oxalic acid is more freely offered.

SHIPBUILDING NOTES.

On the 30th ult. Messrs. R. & H. Green launched the second of two composite lightships they have on order for the Trinity House Corporation. The vessel was built from the designs of Mr. F. C. Goodall, the naval architect to the Corporation. The fittings are generally of teak, of which a liberal use is made; the decks, however, are of elm planking. Special provision is made for ship's stores and the carrying of explosives, an allowance of which becomes necessary in the vessel. It is proposed to use a flashing-power of 20,000 candles in the lamps to be employed. These will be of 60 candle-power each, and placed in an 8ft cylindrical lantern, the reflector being 21in. diameter. The fog signal siren will be worked by a steam motor to compress air in a reservoir from which to draw its supply. Provision is thus made for starting the signal at any moment. The machinery for this purpose is fitted in duplicate in case of breakdown.

On the 17th inst. the "Gertrude," a steel screw yacht of 137 tons gross, was launched by Messrs. A. & J. Inglis, Pointhouse, for Mr. Heys, Belfast. The dimensions are:—Length, 126ft.; breadth, 18ft. 1in.; depth, 11ft. 5in.

HOME INDUSTRIES.

LONDON, 19th June, 1890.

THE MONEY MARKET.—Money was plentiful in Lombard Street in the earlier part of the week, while borrowers were scarce. Later on, however, when advances obtained from the Bank last week fell due, money became harder, but rates have been comparatively light. The discount market maintains its steadiness, Continental exchanges still being against London, and a steady demand for gold for Germany, Holland, and Austria being maintained. The stock markets are depressed and lacking in vitality, and the only securities which have kept up an appearance of vigour are copper shares. Home railways have reacted after the briskness of a week or two, and there is no stimulus to wake them into activity. American railroad stocks are in much the same position, as the fact of the market being heavily committed to a speculation for the rise stands in the way of a recovery. Foreign stocks have had a distinct set-back this week, the cholera scare causing a break in Spanish bonds, which has sympathetically depressed the whole list. Argentines and Brazilians have recovered from the depression which overtook them last week on the publication of disquieting news. The other departments are quiet and featureless.

COMPANIES.—The following companies have been registered since our last report:—Stipendum Stopper Co., Ld., with a capital of £5,000, to carry on business as manufacturers; United States Exploration, Mineral, Coal, and Land Syndicate, Ld., with a capital of £10,100; Dunkley's Patent Wheel and Tyre Co., Ld., with a capital of £10,000; Bowden & Coote, Ld, with a capital of £20,000, to carry on the business of brewers, &c.; Purlis Syndicate Co., with a capital of £5,000, to carry on mining operations in Siam and the Malay Peninsula; Turner, Symons, & Co., Ld., with a capital of £50,000, to carry on the business of paper manufacturers; Dick, Kerr, & Co., Ld., with a capital of £160,000, to carry on the business of engineers; James Lang & Co., Ld., with a capital of £6,300, to carry on the business of manufacturers of firearms, &c.; City of Chicago Brewing & Malting Co., Ld., with a capital of £1,250,000; La Plata and Ensenada Tramways Co., Ld., with a capital of £525,000; New Morgan Gold Mining Co., Ld., with a capital of £40,000; The Wheal Sisters Mining Co., Ld., with a capital of £25,000, to carry on operations in Cornwall; Spanish Prospecting Syndicate, Ld., with a capital of £12,000; Illinois United Breweries, Ld., with a capital of £200,000; The Model Fibre Factory Co., Ld., with a capital of £20,000; South Pacific Mother-of-Pearl Syndicate, Ld., with a capital of £2,500; The Guadalcanal Mining Syndicate, Ld., with a capital of £30,000; Palermo Waterworks Co., Ld., with a capital of £550,000; Stever Lubricator Syndicate, Ld., with a capital of £6,000; The Patent Adamant Stone Co., Ld., with a capital of £65,000; E. & J. Buckley, Ld., with a capital of £15,000, to carry on the business of calico printing and dyeing; Minneapolis and La Crosse Breweries, Ld., with a capital of £200,000; The Column Printing Telegraph Co., Ld., with a capital of £100,000; Orinoco Exploration and Trading Co., Ld., with a capital of £260,000; Jones, Venn, & Co., Ld., with a capital of £5,000, to carry on the business of bicycle manufacturers, &c.; Allen, Everitt, & Sons, Ld., with a capital of £300,000, to carry on the business of manufacturers of brass and copper tube, sheeting, &c.; Tubular Frame Wagon Co., Ld., with a capital of £200,000.

THE INSTITUTION OF ELECTRICAL ENGINEERS.—We understand that the President, being desirous of rendering the annual conversazione especially attractive, hoped to have been able to hold it in a new locale. Every preparation had been made in anticipation of that arrangement, which has, however, unfortunately fallen through, and it being now too late in the season to make any other, the soirée will be postponed until the autumn.

MORGAN'S ELECTRIC SIGNAL SYSTEM.—We referred to this system of police alarm in a recent issue, and now learn that a network will shortly be installed in the Brixton district, with a view to demonstrating its utility on a practical basis.

RUBBER TRADE BENEVOLENT ASSOCIATON.—Mr. Herbert Standring, 131, Finsbury Pavement, E.C., proposes to form a benevolent association for persons engaged in the rubber trades. A meeting will be held in July to discuss details.

CHEMICAL APPARATUS.—We have received an illustrated catalogue and price list of a very great variety of chemical and analytical balances, scales, and weights, made by Messrs. F. E. Becker & Co., 33-35-37, Hatton Wall, Hatton Garden.

THE SOCIETY OF CHEMICAL INDUSTRY.—The annual general meeting of this society will be held at Nottingham, on the 9th, 10th, and 11th of July. The President (Sir Lowthian Bell) will deliver his address at University College, at 11 a.m., on Wednesday, the 9th; in the afternoon a visit will be paid to the Midland Railway Works at Derby; and in the evening the Mayor will hold a reception at the Castle. Thursday morning will be occupied by a visit to the Burton breweries, and the evening by the annual dinner. An excursion to Sherwood Forest on Friday will conclude the business of the meeting. In addition to the above arrangements there are a large number of alternative visits to works, &c, of minor importance.

THE SANITARY INSTITUTE.—The following appointments have been made for the Congress and Exhibition at Brighton, which commences on the 25th of August:—President, Sir Thomas Crawford, K.C.B., M.D.; Hon. Treasurer, the Mayor of Brighton; Hon. Secretary, Arthur Newsholme, M.D.; President, Section I. (Sanitary Science and Preventive Medicine), George Vivian Poore, M.D., F.R.C.P.; President, Section II. (Engineering and Architecture), Professor Roger Smith, F.R.I.B.A.; President, Section III. (Chemistry, Meteorology, and Geology), William Topley, F.R.S., F.G.S.; President of the Conference of Medical Officers of Health, Arthur Newsholme, M.D.; President of the Conference of Inspectors of Nuisances, Alfred Carpenter, M.D., M.R.C.P. On Tuesday there will be a conversazione in the Pavilion Building; on Wednesday, a lecture to Congress, by W. H. Preece, F.R.S.; and on Saturday there will be excursions, and an address to the working classes by Benjamin Ward Richardson, M.D., LL.D., F.R.S. The meetings of the Congress and Exhibition will be held in the Pavilion Buildings.

DANGERS OF THE STREETS OF LONDON.—At the Lord Mayor's Court last week, a Mr. Harris obtained £25 damages from the Corporation of London for injuries resulting from his slipping down on a worn hydrant cover. A worn iron hydrant coverlid is very likely to cause such an accident. Mr. J. C. Merryweather, of Long Acre, has recently introduced a new cover to obviate such mishaps. It consists of an iron tray filled with cement or asphalte, in which lead plugs or strips are inserted. Several have been put down in the Strand, and have been found to answer well.

ADMIRALTY SURVEYS.—The Hydrographer's report of Admiralty Surveys for the year 1889 has just been published. Three vessels were engaged on various parts of the home coast and seven abroad, with 66 officers and 345 men. In each case details are given of the operations of the surveying parties. One matter of interest reported in the book is the subject of a question of which notice was given by Mr. Webb in the House of Commons on Thursday. It had been reported that a danger existed about 20 miles from Cape St. Mary, Newfoundland. On examination and inquiry no rock was found, but fresh evidence was brought as to the existence of the rock, and the "Gulnare" proceeded in the middle of August to make a thorough examination. A fisherman named Patrick Lamb was found in a boat, and he consented to point out the rock, though he knew he was thereby giving up exclusive knowledge of a rich fishing-ground. The rock, now called Lamb Rock, proved to be a small pinnacle with 33ft. of water over it. Lamb's anticipations of personal loss were at once justified by the other fishing-boats crowding to the place in search of cod. The importance of the knowledge of its existence will be seen from the fact that many mail steamers pass this way on their course to the St. Lawrence. Observations place it in lat. 46° 28′ 5″ N., long. 54° 1′ 30″ W.

MANCHESTER, 19th June, 1890.

THE ENGINEERING TRADES.—In spite of the drooping condition of the markets for raw materials, there is no lack of employment among the engineers of this district. Engine builders are fully occupied, and a fair amount of work is coming to hand. Shippers, however, report a little less pressure than existed a few months back, but there is not yet any real ground for complaint. Boiler makers are especially busy, and in some cases are unable to take orders except for very extended delivery. In bridge building there is great activity, and in railway work generally there is plenty of work. The special department of tool making continues to be fully occupied, and few makers have any reason to complain. In textile machinery the tone is good, and all the well-known firms are working at their highest capacity. Many of them have some difficulty in satisfying their customers, and there are no signs of any falling off in the volume of trade in this department. Loom makers are steadily engaged, especially those who make the better class of machines for weaving the higher kinds of fabrics.

FUSTIAN CUTTING MACHINERY.—A scheme is on foot to form a company to cut fustians and velveteens by means of a machine which was patented several years ago. At present all this work is done by hand. The saving in time is said to be 75 per cent., and in addition the cutting is better performed.

TECHNICAL INSTRUCTION.—The special committee of the Manchester City Council have been inquiring into the claims of various educational bodies for participation in the aid to be given by the city authorities. After consideration the committee will make a report upon which action will be taken. The first part of the scheme of the Whitworth Trustees was carried into effect on the 14th inst., when an extensive plot of ground was opened as a public park. In one portion of this an art gallery and school is to be erected. The Whitworth Institute, near the works of Sir Joseph Whitworth & Co., Limited, is rapidly approaching completion.

IMPROVED DUST TRUNKS.—Messrs. Platt Brothers & Co., Limited, have recently introduced an improvement in the dust trunks used between the breaker and opener in cotton factories. In most cases the trunks are provided with small chambers, into which the dirt can fall as the cotton travels along them, and can be afterwards periodically removed. The improvement consists in the introduction of an endless lattice fitted with scrapers or blades between which the dirt falls, and is carried to the end of the frame, where it drops on to a balanced plate. The latter closes an aperture below which a bag is hung, and when the weight of dirt is sufficient it opens the plate and falls into the bag. This is a simple but important provision, and ensures the absolute removal of the dirt at all times without the risks arising when it is allowed to collect. For Indian cotton it is especially useful.

THE LINEN AND JUTE TRADES.—We are unable to report any active movement in the home trade, but in the shipping section there is a brisker demand, and the United States market absorbs very large quantities. The fancy handkerchief trade is in a satisfactory condition. Coarse makes are quiet, and some uncertainty is felt with regard to future prices, which, it is feared, may prove unremunerative to manufacturers, who are already on the losing side. Damasks are slow, the season for these goods not having yet really commenced. Several extensive sales of late have interfered somewhat with the regular course of business, but the effect is not felt greatly, as this period is generally a poor one for linens. Roughs are not inquired for to any extent, and towellings are also dull. Linen threads are moving off freely. The proposed increase in the United States duties does not disturb the trade much, as the largest producers have mills across the Atlantic in addition to those in operation in the United Kingdom. Jute goods are only bought for special orders. The raw material keeps firmer on account of the Silver Bill proposals. Fancy jute carpet squares, with fringed borders, are now a standard feature in this department, and the attention given to designing has increased their popularity.

GLASGOW, 19th June, 1890.

PIG IRON.—A considerable amount of buying has been taking place, and considerable quantities of iron are passing into consumption in spite of the quietness of the shipping trade. The price seems firm, although general trade has fallen off, it being understood that stocks are now very strongly held. The stock in Connal's stores has fallen to three-quarters of a million tons, and is decreasing at the rate of 5,000 tons per week. One furnace was put out of blast this week. There is a strong prospect of labour trouble in England, if not also in Scotland. Altogether the indications seem to point at least to firmness in prices in the meantime, although "bear" speculators are operating to a considerable extent, relying upon the reaction in trade, which certainty affects the shipping and shipbuilding and engineering industries at the moment. Restriction of output, the greatly reduced stocks, and the strong holding of these must, however, have an important influence in the steadying of prices, thus partly neutralising the effect of the falling off in demand.

SHIPBUILDING.—Nearly all the shipbuilding yards in the Clyde district are now suffering from want of work. The ships which were on the stocks in the autumn when trade began to fall off are now leaving them, and orders are very few. A few specifications have been quoted for during the past week or two, but we understand that the prices ruling afford scarcely any margin at current rates for labour and raw materials. With the latter considerably above the rates ruling about three years ago, before the revival of trade had made much progress, the prices for the finished product are now little, if anything, in advance of the low prices of the dull period. The "Princess Victoria," which was built by Messrs. Wm. Denny & Brothers, Dumbarton, has been placed on the Stranraer and Larne route. The "Princess Victoria" has beaten the record, having made the passage, pier to pier, in one hour and fifty minutes. The normal passage by the steamers formerly on the route was two and a half hours.

EDINBURGH EXHIBITION.—The *Chemin de Fer Glissant* has now been in working order for some days, and the telpher line is approaching completion. The Phonograph Exhibition, which was opened by Mr. Stanley, is one of the sights of the show. An interesting experiment will be tried in a few days. A type composing machine will be brought from the printing office of Messrs. T. & A. Constable, printers to the Exhibition, and a compositor will, by means of it, set up in type the utterances of the phonograph. The next step, which, it is understood, Mr. Edison fully expects to make, is to eliminate the compositor. The whole of the five large Galloway boilers supplied by Galloways Limited, Manchester, which provide all the steam required in the Edinburgh Exhibition, have been purchased by the North British Rubber Company for their Castle Mills, Edinburgh.

SCOTCH RAILWAYS, &C.—The operations connected with the Glasgow Central Railway have been begun.—The works at the subway at Finnieston are proceeding rapidly.—The opening of the North British Forth Bridge route has had an influence upon traffic returns, which are up £4,500 on the week in consequence.

FIRE AT THE CALEDONIAN RAILWAY STATION, EDINBURGH.—On Monday last the Princes Street Station of the Caledonian Railway, at Edinburgh, was burnt down to the extent of over one-half of its area. The fire is supposed to have originated in the oil store of the station shortly before two o'clock, and, in spite of all efforts to cope with it, spread so rapidly that in two hours one-half of the roof, with the platforms below it, was a wreck. The platforms were cut, and the fire in the roof subdued, however, before the front of the station was attacked. The passenger traffic was much disorganised, the incoming trains being stopped at Merchiston for some hours, and the outgoing trains being despatched from the goods station in Lothian Road. By five o'clock in the afternoon, however, the trains were being despatched from the unburned ends of the platform of the passenger station. The new station, which is to be erected on the site of that now burned, and which is to extend along Lothian Road, will now be pushed forward with all possible rapidity.

(From our own Correspondents.)

LIVERPOOL, 18th June, 1890.

THE SALT TRADE.—The shipments of salt from the River Mersey during the month of May were very satisfactory, and were greatly in excess of those for many months past. Compared with the exports of a corresponding period last year, the excess of white salt is nearly 10,000 tons, whilst the export of rock salt has nearly doubled. The amount of salt manufactured in Cheshire during the past month is 1,154,649 tons; the white salt shipped from Liverpool was 62,093 tons; from Runcorn, 7,834 tons; and from Weston Point, 6,634 tons; the total amount of rock salt shipped being 8,555 tons.

WORKMEN'S INDUSTRIAL EXHIBITION.—It is proposed to hold a Workmen's Industrial Exhibition in the buildings and grounds of the Walker Engineering Laboratory, and workmen are invited to send models, inventions, ferneries, drawings, &c.; diplomas of merit being offered to such exhibits as the jurors may consider of sufficient merit to receive them. Many of the local firms are also sending exhibits, and other attractions will be offered in the shape of a fairy fountain, electric light, microscopes, art exhibition, &c. The Exhibition is to be opened by the Mayor on the 5th July.

LEEDS, 18th June, 1890.

THE IRON AND STEEL TRADES.—The manufactured iron and steel trades are somewhat improved, though there is still a disinclination on the part of buyers to go beyond present needs. However, the feeling appears to be one of confidence in regard to the future. Some of the forges in this district are by no means fully employed, so that the placing of new work would be greatly appreciated both by masters and men. The Leeds Steel Works have nearly completed the alterations which they have been making, and operations will shortly be resumed there. Extensive building in Leeds and the surrounding district helps to keep ironfounders fairly busy. The briskness observable in the engineering departments is, generally speaking, owing to old contracts. The threatened strike of engineers has been averted. As stated in *Industries* a fortnight ago, the local branch of the Amalgamated Society of Engineers issued circulars to employers asking for an all round advance of 2s. per week. The replies at first were not encouraging, but towards the day that the notices of the men expired several important firms conceded the demand. At the time of writing the addition to wages has been granted at every establishment with two exceptions, the firms who refuse the request employing altogether 80 hands. The apprentices at one or two shops have now struck for an advance of 1s. per week. An important matter for Leeds, having regard to late and present trade disputes, is the formation of a provisional Board of Conciliation for the town, consisting of twelve employers and twelve representatives of labour, the former to be selected by the Leeds Chamber of Commerce, and the latter by the Leeds Trade Council.

THE COAL TRADE.—There is less inquiry for steel for domestic and manufacturing purposes, with a consequent tendency to a reduction of prices. The shipping and locomotive coal trade, however, remains active, and it is expected that fresh contracts for this class of fuel will not be completed without an advance on the rates in operation six months ago.

SHEFFIELD, 18th June, 1890.

IRON AND STEEL TRADES.—Two of the largest concerns in this district have testified by the dividends just announced to the improvement in trade during the past year. Messrs. John Brown & Co., Limited, of the Atlas Works, show a net profit for the year of £115,971 17s. 2d., which, with the balance forward of last year of £9,356 14s. 11d., gives an undivided profit of £125,328 12s. 1d. Out of this the directors recommend a dividend at the rate of 7½ per cent. on the ordinary shares, in addition to the usual 5 per cent. on preference shares. They also write off £50,000 for goodwill, and carry forward £10,547.148. The Staveley Coal and Iron Company, Limited, have a report equally good in every way. The firm have done well, and never were so full of orders as at the present time.

NORTH STAFFORDSHIRE, 18th June, 1890.

THE IRON TRADE.—The downward course of prices continues, and competition is becoming so keen that little hopes of an improvement are entertained just now. Something will have to be done to reduce the cost of production of the raw material, and a reduction in wages all round must shortly occur. It is a fact that current prices are absolutely below the cost of production. It is likely that more blast furnaces will shortly be blown out.

NORTH STAFFORDSHIRE MINING INSTITUTE.—There was a large attendance of members at a meeting of this Institute on Monday last, when Mr. Shepherd, from the offices of the engineers of the proposed ship canal from Birmingham to Liverpool, by way of the Potteries, attended and explained the contemplated scheme. The estimated cost of the canal, irrespective of the necessary outlay for land, is £3,000,000 sterling. The navigation is intended to accommodate vessels to the extent of 400 tons. The scheme is being actively supported by many local gentlemen, and it is likely that Parliamentary powers will shortly be sought.

CARDIFF, 18th June, 1890.

IRON AND STEEL.—Pig iron prices are a little firmer, and in some instances sales have been effected at 6d. per ton above the prices current at the commencement of the month. Hematite is quoted at 54s. 6d. to 55s. for makers' iron. Steel bars for tinplates are quoted at £5 10s. Iron ore is without appreciable change. Rubio is quoted at 14s. 6d. c.i.f. Cardiff and Newport, 15s. 3d. Tees, 15s. 6d. Glasgow, for 50 per cent. iron guaranteed.

COAL AND COKE.—The steam coal market is firm. The shipments during the past week amounted to 250,000 tons. Prices have advanced a little, and for ordinary first-class quality 15s. 3d. has been obtained; seconds, 14s. 3d. to 14s. 9d.; thirds, 13s. 3d. to 14s. Small steam shows an advance of 3d., being now 9s. 9d., and No. 3 Rhondda, small, 11s. 9d. to 12s. 3d. The weakness in the coke trade seems to become more pronounced, consumers having overbought themselves at the commencement of the year. Household sorts are quiet. Freights continue low, and already several steamers have been laid up in the northern ports; and one or two leading shipowners in this district have expressed their intention to follow this course rather than encroach on their reserve funds by running their boats at a loss.

BARROW-IN-FURNESS, 18th June, 1890.

HEMATITE PIG IRON.—There is a quiet market this week for hematite pig iron. Business is slow alike on home and foreign account. The Bessemer trade is quiet because of the limited requirements of steel makers, and there is not much doing in the ordinary hematite trade. Warrants are quoted at 50s. 6d. per ton, but makers are still asking 54s. to 57s. per ton.

STEEL.—Steel makers are busily employed five days a week. Orders are offering to a fair extent for rails at prices varying from £4 10s. to £5 per ton for heavy sections, light sections being at £6, and colliery rails at £7 per ton. The trade in steel shipbuilding material is quiet, and there is no life in the trade in blooms, tinplate bars, hoops, steel wire, billets, &c.

SHIPPING.—There is still a depression in shipping compared with last year. The exports of pig iron and steel during the week have represented 18,019 tons, compared with 18,539 tons in the corresponding week of last year. The aggregate shipments since January have been 492,584 tons, compared with 502,243 tons in the corresponding period of last year.

MIDDLESBROUGH, 18th June, 1890.

PIG IRON.—There was no great muster on 'Change yesterday, but there was some good business done. The improved price was maintained, and it is likely to become better still, seeing that the shipments are good and stocks are falling. No. 3 G.M.B. Cleveland cannot now be got under 41s. 6d. from makers; some, indeed, will not sell under 42s., special brands being from 1s. to 2s. more. In warrants, Cleveland No. 3 G.M.B. cannot be had under 41s. 5d. to 41s. 6d. cash. Foundry iron is becoming scarce. In hematite iron, East Coast brands can be had for 54s. per ton f.o.b. makers' iron, and West Coast hematites at 50s. 7d. to 50s. 8d. per ton cash. The stock in Connal's stores has decreased during the week by 1,114 tons, standing at 99,123 tons on Monday.

SHIPMENTS OF PIG IRON.—Considering that we are approaching the dead season of the year the shipments are exceedingly good. Up till Monday the shipments for June amounted to 38,785 tons, against 35,878 tons to the 16th of May, and 33,560 tons to the 16th of June last year. The shipments to Scotland are improving, now that Cleveland is approaching its normal price compared with Scotch. Germany and Holland are also taking more, as well as other foreign countries.

MANUFACTURED IRON AND STEEL.—There is a better feeling in the finished iron trade and more inquiry. Prices are much the same however. Iron ship plates are at £5 7s. 6d.; angles, £5 5s.; bars, £5 12s. 6d.; steel ship plates, £6 10s., and £6 7s. 6d. would be taken; angles, £6 5s. to £6 7s. 6d. Steel rails are rather better, and £5 would now have to be given for them. Some steel works are still running short time.

SHIPBUILDING.—This industry, which has been very active for some time past, shows signs of falling off. A few orders came lately, but now they seem to have ceased, and the future has so far not much to make builders hopeful.

SUNDERLAND, 18th June, 1890.

SHIPBUILDING.—No new contracts are being booked. Considerable interest has been occasioned in the launching of a large steamer by Mr. James Laing from his higher yard at Deptford. Fourteen days ago the steamer's launch began, but, unfortunately, the vessel stopped in its course. A number of tug steamers were employed to endeavour to complete the launch, but in the attempt they slued the vessel, and caused her to drop on her bilge. The ways have since been relaid, and a further distance traversed. The completion of the launch, however, is still delayed. The river is very narrow at Deptford, and the declivity of the launching ways, especially for large vessels, is usually minimised.—A specialty that is growing in favour with shipbuilders is Mason's skylight, in which the flap is pivoted at mid-length. The s.s. "Taff," recently launched by Messrs. Osbourne, Graham, & Co., North Hylton, has the engine-room fitted with several of these skylights, and the same firm is similarly fitting another steamer.

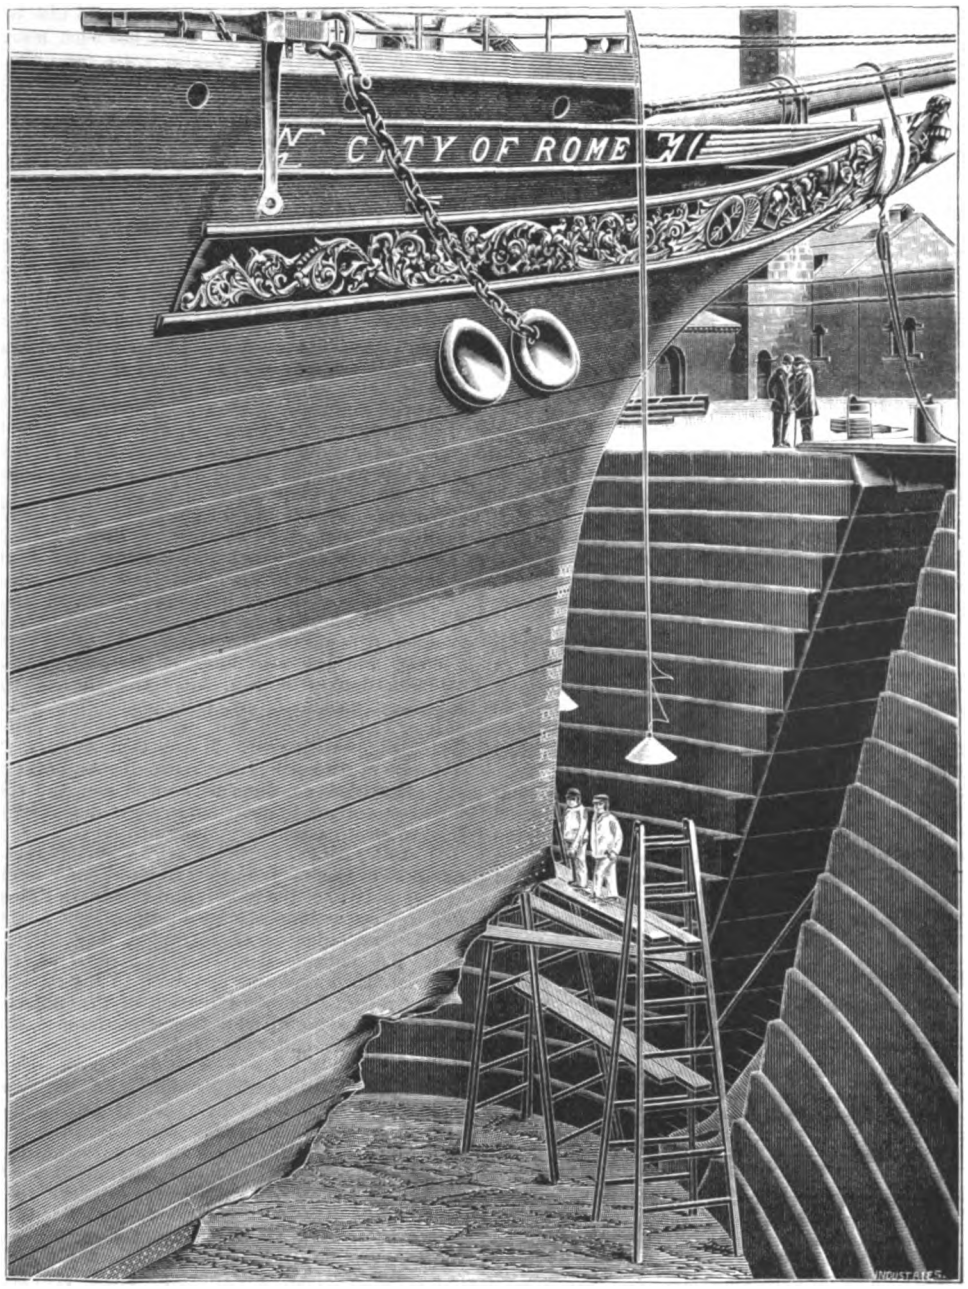
SHIPPING.—The probability of tonnage being laid up on account of the unremunerative freights has been realised, and upwards of thirty steamers are now idle on this and the adjoining river. As yet there has been no recovery of moment, although Black Sea rates are not quite so low as they were a few days ago. It looks as though the bad times had again set in for shipping investors.—Despite the stoppage of Monkwearmouth Colliery, the coal shipments of the last week were satisfactory. They amounted to 77,866 tons, an increase of 14,222 tons over the previous week. Of the total shipments, 38,010 tons went coastwise, and 39,858 to foreign ports. The other shipments included 1,192 tons of coke, 50 tons of crystals, 400 tons of firebricks, and 15,000 dozen glass bottles.

NEWCASTLE, 18th June, 1890.

THE COAL TRADE.—The shipments of coal and coke at Tyne Dock during the week ending June 14th amounted to 126,763 tons, being an increase, as compared with the corresponding week in 1889, of 37,505 tons.

ENGINEERING.—Messrs. R. & W. Hawthorn, Leslie, & Co., who for some years past have had their marine engineering department largely occupied with Admiralty contracts, are now understood to be the recipients of further important orders from the same source. These include the engines and boilers for two cruisers now building at two of Her Majesty's dockyards, and, with the Government work already in hand, will keep the place busy well into next year. Messrs. Clark, Chapman, & Co., of the Victoria Works, Gateshead, have some good orders for their patent windlass (the only one manufactured having riding spring brakes), and are also busy in the production of steam winches, donkey boilers, &c. Though few new orders have been booked lately, it is not anticipated that any serious lack of work will be felt in the establishment during the present year. Messrs. Geo. Angus & Co., manufacturers of Amianthus cloth packing and other engineering specialties, continue to be well supplied with orders, and are resorting to overtime in some departments with a view to meet customers' requirements.

SEAMEN AND FIREMEN'S WAGES.—A conference between members of the newly-formed Shipowners' Association and representatives of the Sailors and Firemen's Union has been held in Newcastle to discuss a proposal put forward by the former for a reduction of wages. A long discussion took place, but nothing definite was arrived at, the sailors' representatives declining to submit to any reduction of the present rates. The consideration of the subject will, it is thought, be resumed at a future conference, the date of which, however, is not yet fixed.



SHIPBUILDING.—No new orders have recently been booked by Tyneside shipbuilders, and the symptoms of incipient slackness in the industry are becoming more marked. Two of the leading establishments on the river have quite half their building space unoccupied, and in several other cases the vacant berths outnumber those that are in use. Shipbuilders, indeed, are loth to take contracts at the prices now obtainable, for while the latter are almost as low as at the worst of the last depressed period, the prices of everything entering into the cost of production—excepting only iron and steel—still stand at the abnormally high rates attained last year, and new contracts negotiated under these conditions must consequently involve loss rather than profit. The lessening of work in the yards has necessarily caused the discharge or suspension of a large number of operatives, and as under existing circumstances this thinning of the ranks of the employed is bound to continue, the outlook for the coming winter is the reverse of cheerful.

DUNDEE, 18th June, 1890.

JUTE AND FLAX TRADES.—The jute market is again a little easier here, but prices have undergone little change. Burlaps, 40in. 10½oz., are quoted at 5¾c. per yard in the New York market. The prospects of the new jute crop are beginning to attract attention. Reports are favourable, and it is expected the crop will be early. The market for loose jute in Calcutta is quiet. First marks of the new crop are quoted on this side at £16 to £16 5s., but there are no transactions reported. The arrivals of jute at this port last week were large. Seven vessels, with a united tonnage of 13,430 tons, came to the port and brought 107,253 bales of jute. Goods are not moving off rapidly, but prices are maintained. Jute yarns are in rather less request, and prices tend to be easier. Prices of Hessians are also rather in favour of buyers. Re-sellers are reported to be obtaining orders by underselling manufacturers. There is a steady business passing in sacking, bagging, and tarpaulin. A strike among the calender workers has been impeding business to a considerable extent during the past fortnight, and it is reported that some buyers have cancelled orders, owing to their being unable to obtain delivery of goods. In flax business is confined pretty much to the satisfaction of immediate wants. The demand for flax yarns is quiet. Orders for linen goods are not coming in freely, and manufacturers are not so well booked forward as they would like. Makers of the finer class of linen goods are, however, well employed, and reports from the Fifeshire district state that a satisfactory feeling is prevalent, the demand being active and prices firm.

ACCIDENT TO THE "CITY OF ROME."

View of the Damaged Stem.

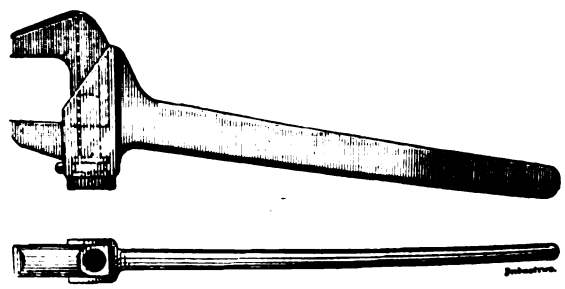
THE SUEZ CANAL.

The report presented by M. De Lesseps to the shareholders of the Suez Canal at their recent annual meeting was of the most favourable kind. It stated that the gross receipts were 69,000,000fr., and the expenditure, with interest at 5 per cent., 32,000,000fr., leaving 37,000,000fr. available for distribution as dividends among the shareholders, being at the rate of 18 per cent., and a slight advance on the previous year. The reserve fund has stood for several years at the highest point required by the statutes, and consequently no deduction had to be made on that account. The works had been extended and materials renewed at a cost of 9,600,000fr., and a further sum of 13,000,000fr. is still available for the same purposes, so that the agreement made in 1886 for the widening and deepening of the canal is being faithfully carried out. Ships drawing as much as 26ft. of water can now pass through it, and the speed is being gradually accelerated. The management appears to be very economical, for the working expenses, apart from the repayment of capital, amount only to 11½ per cent. of the revenue. During last year 3,425 vessels passed through the canal, representing a tonnage of 6,783,187, and yielding an income of 64,412,000fr. The electric lighting arrangements enable a much larger proportion of the ships to pass through during the night, the percentage last year being no less than 71 per cent. of the total traffic as compared with 46 per cent. in 1888. Altogether the position of the canal is most favourable; the only regretable feature about it is that the Egyptian people derive such a small proportion of the direct gain, its Government having bartered it away years ago for what now appears a ridiculously small sum. It was entitled by the constitution of the company to 15 per cent. of the profits after the first charges were met and after 5 per cent. was paid to the shareholders, but it sold its right to this during the whole period of the company's concession to the Crédit Foncier of France for what is little more than four years' purchase of the dividend paid last year. The shares held by the British Government have hitherto only been paid 5 per cent., although they have quadrupled in capital value, owing to the fact that they will be entitled to the full dividend in 1894.

THE SOCIETY OF ENGINEERS.

By the courtesy of the management of the Thames Ironworks and Shipbuilding Company a party of the Society of Engineers, numbering over 100, were conducted over the works on Tuesday last. No less an area than thirty acres of ground is included in the company's operations. There are two large dry docks facing the river, also an extensive forge, rolling mills, foundries, and engine shops. The work done embraces the highest types of warship construction, some of the most important armourclads of our own and foreign Governments having been built there. The company are also able to compete successfully for fast passenger steamers, or where any peculiarity of design is necessary. Any urgent repairs to the fleets which frequent the Thames are very likely to fall into the firm's hands by reason of the accommodation their docks and wharves afford. In addition, a considerable amount of bridge and girder work is done by the firm.

The "Warrior," the first British ironclad, was laid down at this yard, and two fast cruisers are now on the stocks, the "Blenheim" and "Grafton," and when the former is launched, on the 5th of July, a sister ship to the latter will be at once commenced. These are all for our own Government. The "Grafton" has only been in progress eight months. She, therefore, afforded a considerable opportunity to visitors for inspecting the system on which modern men-of-war are designed. She will have twin screws and engines of 12,000 i.h.p., and it is anticipated that she will attain a speed of over 19 knots. The great attraction was undoubtedly the "Blenheim," this vessel being very far advanced towards completion. Indeed, the "ways" appeared to be almost ready for launching. The "Blenheim" is of 9,000 tons displacement, and has been one year and nine months on the stocks. Her engines will be 20,000 i.h.p., and will be connected to twin screws. These are expected to propel the ship at 22 knots with forced draught. The main dimensions of the vessel are:—Length, 375ft.; breadth, 65ft.; and depth, 38ft. The armament will be two 22-ton and ten 6in. breechloading guns, sixteen three-pounder quick-firing guns, together with Nordenfelts and four tubes for torpedo warfare. It will thus be seen that the ship will be one of the fastest and most powerful cruisers in the Navy.



At the termination of the tour, after a vote of thanks had been accorded the company by Mr. Henry Adams, the President of the Society, it was stated that trade on the London river was more promising now than it had been for the past five years. Some four thousand men were now employed at the company's works, and if labour troubles could be avoided there was a likelihood of prosperity for some time to come. Members were specially asked to note the quality of the work they had seen, and the "Warrior" was quoted as an example of excellent past workmanship.

THE ACCIDENT TO THE "CITY OF ROME."

In our last week's issue we gave a short account of the accident which happened to the "City of Rome" upon her last homeward passage; and we are now enabled, by the reproduction of a photograph taken the morning after she was docked in the Birkenhead Graving Dock, to illustrate the extent and nature of the damage done to the vessel's stem. It will be seen that the damage is far more serious than was first anticipated, and if it had not been for the efficiency of the bulkheads the vessel would no doubt have been completely wrecked, with a fearful loss of life. Twenty plates were completely torn off the stem and five ribs were broken, and many others displaced and injured. Immediately after the water was pumped from the graving dock, a gang of men from Messrs. Clover, Clayton, & Co.'s yard, Birkenhead, commenced the repairs; by working double shifts these have progressed rapidly, and it is expected that the vessel will be ready to proceed to New York on the 28th inst.

IMPROVED CLYBURN SPANNER.

We illustrate an improved Clyburn spanner which is being put upon the market by Mr. John Woodward, St. Ann's Square, Manchester. The chief feature in the spanner is the formation of the sliding jaw, and the method of moving it. As will be noticed, the controlling screw is revolved from one side of the spanner head instead of the bottom of the jaw as usual, and the movable

jaw is so made that even when fully open it has a good bearing to resist the thrust put on it when in use. The spanner is made in malleable iron at a low cost, and is thoroughly strong and serviceable, without being heavy. The adjustment is made with more ease and exactness than with the older type.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week.

All accounts are payable to GEO. CAWLEY, *358, Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

FRIDAY, 20TH JUNE, 1890.

BRITISH SHIPPING AND SHIPPING FACILITIES.

WITHIN the last few days a very remarkable Blue Book has been published, showing the astonishing progress that has been made in the shipping trade of the United Kingdom during the last two years. It shows the recent progress of the shipping trade of the United Kingdom with foreign countries and British possessions, and gives full details of the entrances and clearances into and from every port in the United Kingdom. It is very gratifying to find from this bulky statement that the shipping trade was larger in 1889 than in any former year in the history of the country, and that the extent of progress made during the last three years has been something truly portentous. This remark applies equally to the home and to the foreign trade, but more especially to the latter. The total entrances and clearances in 1889 reached the enormous figure of 161 millions of tons, employing 730,000 vessels. This compares very favourably with the returns for 1887, when the entrances and clearances amounted to only 149 millions of tons, an increase of some 12 millions of tons, and when 676,000 vessels, or 54,000 less, were engaged in the business of our ocean transport.

The following statement shows how the entrances in the foreign trade of our principal ports compare in 1887 and 1889:—

	1887.		1889.	
	Ships.	Tonnage.	Ships.	Tonnage.
London	10,457	6,880,000	10,730	7,550,000
Liverpool	4,477	5,186,000	4,689	5,789,000
Tyne Ports	4,653	2,368,000	5,474	2,953,000
Cardiff	3,620	2,536,000	3,872	2,913,000
Hull	3,106	1,816,000	3,266	2,008,000
Glasgow	939	972,000	957	1,058,000

The enormous preponderance of London over all other ports is the point in these figures that will most arrest attention. The Thames, indeed, has long maintained the lead as an import centre, and is likely to continue to do so, owing to its great distributing facilities and the enormous population whose food supplies depend on the sea. The exports, however, are tending rather to go to the other ports, as will be seen from the next table of clearances from the same ports in the same years:—

	1887.		1889.	
	Ships.	Tonnage.	Ships.	Tonnage.
London	8,094	5,284,000	8,029	5,566,000
Liverpool	4,005	4,758,000	4,064	5,147,000
Tyne Ports	6,608	3,665,000	7,970	4,786,000
Cardiff	5,925	4,714,000	6,281	5,401,000
Hull	2,769	1,535,000	1,827	1,582,000
Glasgow	1,385	1,464,000	1,439	1,621,000

One of the features of this table is the rivalry between London and Liverpool. Some years ago London was behind Liverpool as a port for exports, whereas now it appears that London has got a considerable lead, and that, too, in spite of the fact that the number and tonnage of the vessels on the Liverpool register—at any rate, in sailing ships—is higher than that of London. No doubt the difference in favour of London is largely due to the better facilities afforded to vessels, but that is not the only reason. It is not a secret that the Liverpool dock dues are exceptionally high, and they are not likely to command the lion's share of the shipping trade if they keep up such relatively high dues. Then, again, vessels can now enter the Thames at almost all hours of the day and night, whereas in the case of Liverpool they are bound to wait for tides and for the convenience of the port authorities. Liverpool, however, has the advantage of being much nearer than London to most of the principal foreign ports, and more especially to the chief ports of the United States, with which our largest business is done.

One of the most remarkable of the recent developments of our local taxation is that incurred by port and harbour authorities. This is, of course, the price that we have to pay for the possession of the most remarkable and efficient shipping facilities in the world. The growth of this system is comparatively modern. Even Liverpool, which has a stream so strong, and a situation so exposed, as to threaten serious danger to shipping, did not begin to provide dock accommodation until 1709, and this dock supplied all the requirements of the port for half a century, when a second one was commenced. But Liverpool has now a series of some thirty or more great docks, with a total water area of over 600 acres, approached by some fifty locks with gates varying from 40ft. to nearly 100ft. in width. Besides these, there are many graving docks for the repair of ships, and it has been well remarked that these, with the warehouses, sheds, and machinery, "make up an aggregate of works which, though not perhaps so showy as some of the architectural productions of the Romans, or of some modern nations, are, when compared with those of Birkenhead, unrivalled as specimens of solid utilitarian grandeur."

There are, however, cases where the results do not appear to have quite justified the high expectations formed as to the results of the works projected or carried out for the improvement of the trade of a port. Barrow-in-Furness may be quoted as an example. Up to a certain point the growth of this port was remarkable. The town and trade increased with phenomenal rapidity. The obscure fishing village became a considerable town, with mushroom-like advances. The pilgrim fathers of the place looked forward to its becoming a second Liverpool, and, perhaps, even putting that notable mart of shipping in the shade. They, therefore, undertook an expenditure of about two millions on the docks and quays, but against this their total income from 1868 to 1883 was only £116,838, a sum which is only equal to the payment of 5·8 per cent. on the expenditure for a single year! During the same period the tonnage of the vessels using the docks increased from 255,000 to 539,000 tons. The total tonnage that had entered and cleared from these magnificent docks to the end of 1882 was about 5½ millions, and the average receipts or tolls received per ton was about fivepence. In 1889 the Barrow entrances and clearances only amounted, for the foreign trade, to 196,000 tons.

The tendency of the shipping trade to undergo rapid expansion within recent years may be illustrated by a very large number of examples. That of the Cardiff Docks is perhaps one of the most striking, as it illustrates the recent development of the trade in respect alike of the greater tonnage and the larger size of vessels dealt with. In 1863 the total number of vessels entering these docks was 9,299, and they registered a total of 1,616,000 tons. Twenty years later the number of vessels was 9,489, and the tonnage 3,482,000. In 1889 19,256 vessels entered and cleared, with 9,487,000 tonnage. In the first interval there was an increase of 1,866,000

Digitized by Google

tons, or about 109 per cent., in the tonnage, but of only 190 in the number of vessels. Put in another way, the average size of the vessels that frequented the Cardiff Docks had increased from 174 to 370 tons during these twenty years, but, of course, both averages include a number of very much larger vessels, for which extra accommodation had to be provided, alike in the way of deeper docks, greater quay space, wider dock gates, and otherwise. These docks, like all docks that are to be equal to the requirements of the present day, must be capable of accommodating the largest vessels afloat.

It is interesting to compare the British shipping returns with those of France, our nearest neighbour. The commerce of France by sea is carried on at fifty principal ports, and a few smaller ports, the principal being the ports of Marseilles, Havre, Bordeaux, and Cette. At these ports in 1888 the number of ships that entered and cleared, with their tonnage capacity, and the actual tonnage of merchandise transported, were as under:—

	No. of Vessels.	Tonnage Capacity.	Tons Carried.
Marseilles	13,111	8,610,000	4,235,000
Havre	9,921	4,387,000	2,535,000
Bordeaux	20,622	3,067,000	2,457,000
Cette	4,980	2,175,000	1,014,000
Dunkirk	4,038	1,645,000	1,806,000
Total of fifty chief ports	125,124	30,218,000	20,010,000
Total for all French ports	156,282	32,236,000	21,263,000

The *rapport* between the tonnage capacity of the vessels employed in 1887 and the tonnage of merchandise actually carried varied considerably as between one port and another, being as low as 0·231 in the case of Calais, and as high as 1·120 in the case of Bayonne. There are no similar returns of tonnage capacity issued officially for England, which is a matter for regret, as a very useful comparison might thereby have been instituted.

The French Government, during the last ten or twelve years, have expended large sums of money over the principal ports of their country, in order to adapt them better for the purposes of commerce. This expenditure has been, to a certain extent, justified by the results, but not to the extent that might have been expected. The exports and imports of general commerce at each of the principal French ports, in each of the years 1878 and 1887, have been as under (1 = 1,000 tons):—

	Year 1878.		Year 1888.	
	Imports.	Exports.	Imports.	Exports.
Marseilles	2,145	884	2,219	1,218
Havre	1,526	366	1,410	549
Bordeaux	823	442	1,281	718
Dunkirk	878	106	1,299	183
Rouen	577	145	935	161
St. Nazaire	439	74	658	99
Cette	413	158	719	190
Dieppe	509	80	500	81
Boulogne	316	61	261	104
Calais	317	25	199	41

The above figures do not include the returns of what are called *commerce spécial*. Such as they are, however, they comprise all but a fraction of the trade, and they show how infinitely superior is the commerce of the United Kingdom, and how much more rapidly our own trade is being developed.

THE FOREIGN TRADE OF JAPAN IN 1889.

The returns of the Japanese Customs for the year 1889 of the foreign trade of the country show an increase of a little over $5,000,000 as compared with 1888, the figures being $136,164,472, against $131,160,444, and the increase was due almost entirely to exports, which amounted last year to $70,069,705, while the imports remained almost stationary. The total trade was distributed as follows:—Great Britain and her possessions, $55,498,530; United States, $31,426,044; France, $17,592,893; China, $14,642,205; Germany, $6,526,282. Although these figures show that British trade with Japan is equal to that of the United States, France, and Germany together, still it ought to be noted that British trade, excluding Hong Kong, has fallen by about $3,000,000 during last year, while that for the United States shows an increase of almost the same amount. That of France and Germany shows a considerable decrease. In the British imports the chief decrease is in British and Indian yarns—over a million dollars—caused, no doubt, by the growing manufacture of yarn in Japan, and the consequent increase in the import of raw cotton from China. In 1887 this latter item was under a million dollars; in 1889 it was nearly five millions and a-half. The other departments of British trade which have fallen off are gunpowder, bar and rod iron, rail iron, pig iron, iron nails, machinery, Portland cement, grey shirtings and woollen cloths. On the other hand, there was an increase in blankets, Turkey reds, cotton drills, cotton velvets, hats and caps, plate and sheet iron, railway carriages, steam boilers, and steel.

We have heard a good deal about the increase of German trade in Japan, but, with the exception of flannels, the increase appears to have been in the less important departments. The German trade in flannels continues to increase with great rapidity, a fact which we believe to be largely due to the bad material which the British merchants supplied some years ago. In 1887 the trade amounted to $222,267, in 1888 to $406,601, and in 1889 to $886,288, while last year the British trade in flannels was only $129,686. The chief increases in German trade took place in the following articles: analyne dyes, gunpowder, iron nails, lamps, iodide of potash, salicylic acid, sheet zinc, and satins—that is to say, in articles the manufacture of which require special technical skill, many of which the Germans have monopolised in this country as well as in Japan. Taken, however, from 1887, the British trade, which is eight times the bulk of that of Germany, has increased 37 per cent., while that of Germany increased only 22 per cent., so that the fears regarding Germany ousting Britain are not well founded. The great staple of American trade in Japan is kerosine, which was imported last year to the value of $3,783,193, while a considerable trade was done in leather, clocks, and flour. One-half of the French trade with Japan is in *mousseline de laine*, while the remainder is taken up with fancy goods of all kinds.

America is the best customer of Japan for the export of her products, of which the chief are silk and silk goods, sulphur, tea, and rice. Great Britain takes rice, camphor, silk goods, tobacco, and copper. Of late years France and the United States have become the chief markets for Japanese silk, and the export is steadily increasing, while that of tea is diminishing.

THE ROYAL SOCIETY CONVERSAZIONE.

The second conversazione of the session was held on the 18th inst., in the Society's rooms, at Burlington House.

Great interest was shown in Professor Fleming's demonstration of some of Professor Elihu Thomson's recent experiments on electromagnetic repulsion. The apparatus employed for the demonstrations was the same as exhibited by Professor Thomson at the Paris Exhibition last year, and was lent by him for exhibition to the Society. A striking experiment consisted in placing rings of good conducting material, such as copper or zinc, over the upper end of the vertically placed core of a powerful electromagnet excited by an alternating current supplied by a 10 h.p. transformer, lent by, and fed from the circuits of, the London Electric Supply Corporation. When the electromagnet was excited by this alternating current the rings were projected upwards to a considerable height. By placing a paper cylinder over the end of the core and slipping the rings on to it, they were shown suspended in the air, and two rings placed over the paper cylinder at the same time were seen to attract each other owing to the currents induced in them being in the same direction and phase. A copper disc placed over the end of the electromagnet core was shown to be powerfully repelled. In addition to these experiments, various others made by Professor Thomson, and described in Professor Fleming's lecture before the Society of Arts last month, were repeated and explained.

Mr. Shelford Bidwell exhibited his interesting experiments of the electrification of a steam jet, which the author considers may throw some light on the intense blackness, often tempered by a lurid yellow glow, of thunderclouds. The experiment was originally shown at a meeting of the Physical Society. Among other experiments which have been exhibited at the Physical Society, and described elsewhere in our columns, we may mention Dr. Kœnig's experiments on the production of beats and beat-tones, exhibited by Professor S. P. Thompson, with the aid of some of Dr. Kœnig's magnificent apparatus, which he brought over for exhibition at a recent meeting of the Physical Society. Mr. C. V. Boys also repeated his oscillating spark experiment, and exhibited his series of photographs illustrating the formation of drops, and the thaumatrope constructed from the photographs.

Professor Roberts-Austen gave an experimental demonstration of the determination of the melting point of gold by means of Le Chatelier's pyrometer, consisting of a thermo-couple, composed of platinum and platinum alloyed with 10 per cent. of rhodium, connected with a dead-beat d'Arsonval galvanometer. The pyrometer scale had been calibrated by heating the thermo-couple to certain known temperatures determined by means of the air thermometer.

Professor Worthington exhibited his ingenious apparatus for stretching a liquid and measuring simultaneously the stress and strain. The liquid (alcohol was the one shown) is deprived of air by prolonged boiling, and sealed in a strong glass vessel, which it almost fills at a particular temperature. On raising the temperature the liquid expands and fills the whole. On now lowering the temperature the liquid is prevented from contracting by its adhesion to the walls of the vessel, and remains distended, filling the whole and tugging at the walls. The tension exerted is measured by means of the change in capacity of the ellipsoidal bulb of a thermometer sealed into the vessel, and called the "tonometer." This bulb becomes slightly more spherical, and therefore more capacious, under the pull of the liquid, and the mercury in the tonometer stem falls. The tension corresponding to the fall is previously determined from observation of the rise produced by an equal pressure. The liquid is caused, at any desired instant, to let go its hold and spring back to its original volume by heating for a moment, by means of an electric current, a fine platinum wire passing transversely through the capillary stem that forms part of the vessel. The space left vacant in the tube represents the amount by which the volume of the liquid was extended. A correction has still to be applied for the alteration of the volume of the glass vessel. By means of this instrument measures have been obtained up to a tension exceeding seventeen atmospheres, or 250lb. per square inch.

The Postmaster-General exhibited, under the superintendence of Mr. W. H. Preece, three of Hughes' type-printing telegraphs, which were connected with Paris, Berlin, and Rome respectively, and during the evening the President held communication with Professors Helmholtz and Dubois Reymond in Berlin, Professor Mascart in Paris, and Professor Cannizaro in Rome.

Mr. W. B. Croft exhibited a series of breath-figures, showing that polished surfaces placed near to bodies in low relief often take an impression of the detail, which is made visible by breathing upon the surface. When these figures are examined with a microscope, water particles are found to cover the entire surface, the effect being black or white according as the particles are larger or smaller.

Mr. G. F. Symons exhibited a "brontometer," or thunderstorm-measurer, devised by himself and MM. Richard Frères, the makers of the instrument, in order to investigate the causes of the rapid barometric variations frequently observed during heavy rains and thunderstorms. The endless paper is carried under the recording pens at a speed of six feet an hour, so that the time of any phenomenon can be easily read to half a second, each 60th second being automatically recorded. The velocity of the wind is continuously recorded by one of Richard's anemo-cinemographs, and the atmospheric pressure by a modified form of their statoscope, which is so delicate as to give 30in. for each inch of the mercurial barometer, or about three times the scale of a glycerine barometer. There are mechanical arrangements whereby the observer records:—(1) The commencement, variation in intensity, and termination of rain; (2) the instant of each flash of lightning; (3) the commencement and duration of each clap of thunder; (4) the commencement, variation in intensity, and termination of hail. As all these phenomena are recorded on one paper, with a single time scale of 0·02in. per second, it is evident that their precise sequence and correlation will be recorded.

Dr. Pole showed a series of diagrams illustrative of colour blindness, and Dr. Grossmann exhibited his apparatus for testing for colour blindness, consisting of a series of test plates, each built up of small squares of glass of various tints in pairs, the squares being arranged so as to show a letter or figure in one tint upon a ground of the other.

The Director-General of Ordnance Factories exhibited the new magazine rifle now being made for the British Army. It has a calibre of 0·303in., is on the bolt principle, and is provided with a detachable magazine underneath to hold eight cartridges; a cut-off on the right side enables it to be used as a single loader. It has two sets of sights; the ordinary ones are graduated up to 1,900 yards, the long range sights on the left side up to 3,500 yards. The sword-bayonet, which is attached

Digitized by Google

underneath the barrel, has a double-edged blade 12in. long.

The Director-General of the Geological Survey exhibited a series of specimens illustrating deep borings in the South of England, and also a series of specimens illustrative of dynamical metamorphism in rocks. The effects of mechanical movements, even among the comparatively young and soft rocks of the South of England, were illustrated by two specimens from the under surface of a "thrust-plane" in the vertical chalk of the Dorsetshire coast. They show how the chalk has been indurated, smoothed, and polished by the movement of the overlying mass.

Mr. Norman Lockyer and Mr. Isaac Roberts exhibited some interesting astronomical photographs, and the Royal Meteorological Society showed a series of photographs of lightning flashes and of electric sparks, illustrating the formation of dark images of lightning flashes. They also exhibited a series of photographs, showing the devastation caused by the tornado at Rochester, Minnesota, in August, 1883. The great force of the wind is illustrated in a striking manner by two of the photographs, one showing a horse impaled on a large branch of a tree, and the other, pieces of straw driven end-on into the bark of trees.

There was also a large number of interesting natural history and miscellaneous exhibits. Of the botanical exhibits, the most important from an industrial point of view was a series, shown by Mr. D. Morris, of seed and seedlings of the sugar cane.

Legal Proceedings.

OAKEY *v.* FLATAU.

This was an action tried before Mr. Justice Kay on the 9th inst., for an injunction to restrain the infringement of a registered trade mark, and damages for the wrongful passing off of defendant's goods as being of plaintiffs' manufacture. The plaintiffs are Messrs. John Oakey & Sons, the manufacturers of the well-known "Wellington" knife polish, and the defendant is Mr. Wm. Flatau, trading and sued as W. Flatau & Sons. The defendant is, like the plaintiffs, a dealer in knife polishing powder, but he does not manufacture what he sells, and the act complained of was his use of a label so closely resembling the plaintiffs' trade mark as to be calculated to deceive the public. It was a point made against the infringing mark that the resemblance to the original was rendered closer by the employment of the same colours.

In the result, the learned Judge held that the plaintiffs' case had been made out, and gave judgment accordingly, remarking that the defendant had gone as near as he dared go to the exact imitation of the plaintiffs' label. It had been proved in the course of the case that knife polish was a commodity which was purchased in large quantities by servant girls and persons in very humble circumstances. This, therefore, was the class of persons whom the Court was called upon to protect, and he entertained no doubt that the defendant's label was calculated to deceive them. Referring to the circumstances in which the design of the label was produced, the learned Judge observed that the defendant's account of what passed between himself and the printer when the latter received the order to design the label did not advance the defendant's cause. He had sworn that it had been arranged that the general idea of the label should be something in entire contrast to the label used for the "Wellington" polish, with which the "Nelson" would naturally be regarded as an indirect competition. The result of those instructions was that the designer slavishly copied Oakey's mark. There was in the one an oval enclosing a head of Wellington, and in the other an oval enclosing a head of Nelson. The defendant explained his adoption of the head of Nelson as a trade mark by the circumstance that he had purchased the Nelson mark from somebody else. Then, again, the defendant's mark stated that the powder was manufactured by W. Flatau & Sons, a statement which was untrue. In both these respects the defendant's label was assimilated to the plaintiffs' label, on which appeared the words "Manufactured by Oakey & Sons." The learned Judge also referred to the colours of the two labels, which, as already explained, are strikingly similar.

He next proceeded to consider the alternative design of label which the defendant proposed to use in future. He remarked that the only alteration consisted in the substitution of a lozenge for the oval frame, and that he had no doubt, especially having regard to the class of persons who chiefly buy this powder, that the altered design was calculated to deceive and would have that effect. He, therefore, granted an injunction restraining the defendant from using any canister got up like the plaintiffs' proved in the action, and directed an inquiry as to the profits derived by the defendant from his wrongful sale of goods under the infringing mark; awarding to the plaintiffs also the costs of the action.

Letters to the Editor.

COMMUNICATION BETWEEN FRANCE AND ENGLAND.

To the Editor of "Industries."

Sir,—With reference to your article on this subject, I am pretty certain that none of the three schemes of crossing will be carried out. Sir Edward Watkin is a persevering man, but he would do well to devote himself to the Underground Railway and his new Tower, and let the tunnel sink into oblivion. The prejudices, both of a large section of our military advisers, and also of the general public, are so strong against it, that there is no chance of the scheme being allowed to come to maturity.

To the combination of piers and tunnel there is less objection from a military point of view; but if carried out it would have to depend almost solely on goods traffic, for passengers would be chary of experimenting with what may be described as a kind of maritime switch-back.

As regards the third project, its financial results would be of such an exceedingly problematic nature that I am dubious whether even an English public, ready though it is to throw money into bad companies, would care to trust its coin in such a venture. There is no doubt that the idea is a magnificent one from an engineering point of view, and I believe it to be practicable, but there is no use doing the work merely for glory. If the French are willing to go to the expense of putting it up, good and well, but it would be a pity to see English money going astray upon it.

Yours, &c.,
Thomas Davis.

London, 16th June, 1890.

BRITISH MANUFACTURES ON THE CONTINENT.

To the Editor of "Industries."

Sir,—I am not sorry to find the cudgels taken up against the views I ventured to put forward on the above subject in a recent issue. The points of my argument do not, however, appear to have been fully grasped. Surely we are in the same position with regard to protective duties, say, in Russia, as our competitor Sweden. Yet it is nevertheless the fact that considerable orders for one of our leading lines—viz., steamers—are continually passing from the former to the latter. I am unable to follow, therefore, your correspondent's reasoning that these duties account for the loss to us, for it is to be presumed that the same tax is levied in the one instance as in the other.

It is so very easy in this as in other matters to wave the hand and dismiss the question with the magic word "protection." I say that in Continental countries we are in precisely the same condition as regards the sale of goods as any of our neighbours. There is the obtaining of the order, the suitability of the article for the particular market, the freight and terms of payment. Assuming there is no difference in the tariff at the Customs in the two cases, I still hold that any other difficulties, as above enumerated, become practically absorbed in the one of representation. If this be efficient, provision is at the same time assured for the character of the goods. As to freight, we ought generally to be as well off as our competitors. Even when we turn to the mode of payment, this is also but allied to the question of a thorough knowledge of the people with whom business is to be transacted, and this cannot be attained without the power of conversation. Englishmen, on an average, under our present system, are not linguists; the consequence is they are handicapped in communicating with customers. To employ foreigners on the behalf of our manufacturers would not be a good policy for obvious reasons. The field, therefore, remains in a great measure quite untouched. I will only add that if your correspondent "T. R." will take any one country as an example, he will see that, as exporters, we are no worse off than another in passing the protective barrier raised up equally against both. What is wanted is a system whereby our young business men would be placed on an even footing with those of other European nations, and, as we are not alone in the race for supremacy now, the matter is one requiring urgent attention.

Yours, &c.,
Trader.

Manchester, 18th June, 1890.

DESCRIPTION OF A COMMERCIAL TRIAL OF A ½-KILOWATT ELECTRIC LIGHTING PLANT.

To the Editor of "Industries."

Sir,—In February last year I put up a complete plant for lighting my house by electricity. The house is a small one, and thirty 8 candle-power lamps suffice for all my purposes. A half-horse nominal "Otto" gas engine drives a 1-kilowatt shunt-wound Statter dynamo, which charges an accumulator consisting of sixteen 11-L. E.P.S. storage cells (1888 pattern). On the switchboard the usual provision is made for switching end cells in or out of the charging or discharging circuit Means are also provided for measuring the current and the electromotive force.

As trials of so small an installation are not numerous, it occurred to me that an account of a trial I made a few days ago, which was carried out on purely commercial lines, might not be altogether without interest. The fact should be borne in mind that the conditions of the trial were not those obtaining in a laboratory. The gas engine had not been cleaned or overhauled for the occasion, the slide had been running for about 25 hours since last being cleaned, the cylinder had not been touched for over a year, nor were any extraordinary precautions of any kind taken to ensure good running or high efficiency—in fact, the condition of things may be perhaps best summed up in stating that the cells required recharging in the ordinary course, and that I took this opportunity of finding out what my electric light was really costing.

As I pay for my gas through the company's meter, I measured the gas consumption by this meter, and did not use any special type.

The quantities measured were:—

(1) Gas.
(2) Potential difference at the terminal of the dynamo.
(3) Current flowing in the external circuit.
(4) Speed of engine.
(5) Speed of dynamo armature.

The instruments used were an Evershed gravity voltmeter and gravity ammeter. I checked both instruments before using them as well as I could, and found that the voltmeter read too low. I could not determine the coefficient of error with great accuracy, but as well as I could ascertain it I found that about two volts should be added to the mean reading. The ammeter was very fairly correct.

The engine was started at 5 20 p.m., but regular readings were not taken until 6.7½ p.m. The voltmeter and ammeter were read every ten minutes, the engine and armature speeds being taken at the same time intervals, until 6.59½, when I was obliged to leave home. I got another set of readings at 8.25, and another at 10.1 p.m. As under ordinary circumstances the engine runs without skilled attendance, I did not touch the brushes during the whole run. This, of course, accounts for the speed of the engine increasing as the cells become charged.

The measurement of the gas consumed is important, and I may just point out how the meter readings were obtained. The meter registers 100,000, 10,000, 1,000, and single cubic feet. I therefore timed the speed of revolution of the small hand marking cubic feet, and found that a little less than two complete revolutions were made in five minutes. Thus I was able to read it every ten minutes by noting the lag behind a complete revolution. To prevent magnetisation of my watch, I took the revolutions of the armature per 180 revolutions of the engine, and, immediately after, timed the speed of the engine per minute. The slip of the belt may, I think, be reasonably taken as constant over the period of regular readings, so that the armature speeds were indirectly obtained quite accurately. The observations are given below. Everything happens as one would expect. The e.m.f. rises gradually, the specific gravity of the solution also rises, and, after a while, there is an appreciable diminution in the amperes. The speed of the engine rises, as the brushes are not shifted to suit the decrease in the effect of cross magnetisation owing to the strengthening of the fields and to the decrease of current flowing in the armature.

Electrical Readings.

Time.	Volts.	Amperes.	Sp. Grav. of Solution in Cell No. 6.
6·7½	34·6	18·95	1,190
6·17½	34·9	18·50	—
6·27½	34·9	18·70	1,191
6·37½	34·9	18·60	—
6·47½	35·0	18·50	—
6·57½	35·0	18·00	—
8·25	35·0	18·00	1,193
10·1	36·0	12·80	1,195
Mean values from 6·7½ to 6·57½.	34·9	18·54	
+ correction	2·0		
	36·9		

This value of the e.m.f. (36·9) is probably very near the correct one. I took the e.m.f. of the cells with a voltmeter specially arranged for this purpose, and found an average e.m.f. of 2·3 volts per cell.

Speeds of Engine and Dynamo.

Time.	Revolutions of Armature per 180 Revolutions of Engine.	Revolutions of Engine per Minute.	Revolutions of Armature per Minute.
6·11½	1,383	—	—
6·13	—	183	1,406
6·21½	1,385	—	—
6·23	—	185	1,423
6·31½	1,385	—	—
6·33	—	185	1,423
6·41½	1,383	—	—
6·43	—	185	1,420
6·51½	1,385	—	—
6·53	—	188	1,408
8·27	1,401	—	—
8·28	—	189	1,471
10·1	1,476	—	—
10·2	—	192	1,574

The ignitions of the gas engine were quite regular throughout.

Gas Meter Readings.

Time.	Revolutions of the Small Hand indicating 2 Cub. Ft. per Revolution.	Differences.
6·9½	0·00	3·97
6·19½	3·97	3·91
6·29½	7·88	3·92
6·39½	11·80	3·92
6·49½	15·72	3·77
6·59½	19·49	

Means revs. of small hand per ten minutes = 3·9 nearly.
From these results the following is deduced:—
Gas consumed per hour, 46·8 cubic feet,
Costing at 2s. 6d. per 1,000 cubic feet, 1·41d.
Volts at dynamo terminals = 36·9 volts.
Current in charging circuit = 13·54 amperes.
Watts through cells = 499·6 watts
(or, say, half a kilowatt).

Hence:
Cost of gas per kilowatt, 2·82d.

The allowable discharge rate of my cells is 22 amperes. I rarely discharge higher than 5 amperes; hence it may reasonably be assumed that the cells are about 90 per cent. efficient. This is further borne out by observation and experience of

Digitized by Google

their working over a long period. Supposing them to be 90 per cent. efficient, the cost at the lamp terminals would be $2{\cdot}82 \times \frac{10}{9} = 3{\cdot}13$d.

To this must be added a proportionate amount for oil and waste. This item amounted in the last year to 41s., owing to the high class oil necessary for the engine.

Now, at a very liberal allowance, the lamp hours for the past twelve months have been 9,000. Assuming the lamps to be 35-watt lamps, this is equivalent to 250,000 watts produced by the machine—allowing for counter-efficiency of the cells.

There is very little doubt that the oil has been far too plentifully used by my servant, whom I have always warned against letting the engine slide run dry. However, taking the figures as they stand, we must add

$$\frac{41 \times 12}{250} = 1{\cdot}96\text{d.}$$

to the cost of production per kilowatt. This is a large item, being 41 per cent. of the total cost of production, which now becomes 4·78d., or, say, 4¾d. per kilowatt.

No allowance has been made for attendance, depreciation, &c. It would be difficult to estimate this in my case, but it should be borne in mind that some further amount should really be added to cover this.

It may be of interest to compare the working of the gas engine. The engine is five-and-a-half years old, and was second-hand when I bought it. I indicated it some months ago, and also measured the brake h.p. by a rope brake, similar to that used by Professor Kennedy at the Society of Arts trials last year. Inasmuch as there has been no indication of any alteration in the performance of the engine since then, it may, I think, be fairly assumed that these measurements represent very nearly the

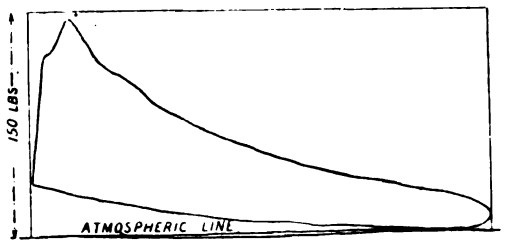

Fig. 1.—Rev. 171 per Min.; I.H.P. 1·8.

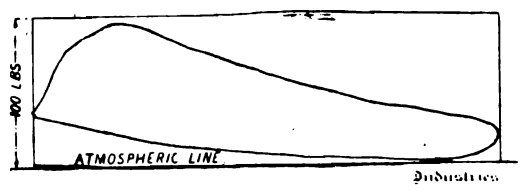

Fig. 2.—Rev. 190 per Min.; I.H.P. ·51.

actual state of things. I took a good many cards. One is shown in Fig. 1, taken at full load. Fig. 2 shows a card taken when the engine was simply driving itself.

The i.h.p. was:—

Full load	1·8
Running light	0·51

The brake trial gave the following results:—

Weight on brake	15lb. 14oz.
Mean reading of spring balance	2lb. 2oz.
Mean revolutions per minute	184.
Periphery of fly-wheel	131·88in.

Ignitions quite regular.

$$\text{b.h.p.} = \frac{13{\cdot}75 \times 131{\cdot}88 \times 184}{12 \times 33000} = 0{\cdot}84$$

Thus it seems to make some difference—at least to a gas engine—at what rate work is absorbed in internal friction when running light and when running with a load on.

We can also from these results get a rough idea of the efficiency of the dynamo:—

0·84 b.h.p. = 627 watts;

therefore commercial efficiency of dynamo

$$= \frac{500}{627} = 79 \text{ per cent.}$$

$$\text{electrical efficiency} = \frac{500 + \left(36{\cdot}9 \times \frac{36{\cdot}9}{53}\right)}{627}$$

= nearly 84 per cent.

(the resistance of the shunt hot being 53 ohms. The armature resistance is so small that the energy lost in it may reasonably be neglected in so rough a calculation).

These efficiencies are certainly good for so small a machine, and the performance of the gas engine is also very creditable—viz., 26·1 cubic feet of gas per i.h.p. per hour. But, of course, I cannot claim scientific accuracy for these figures, as the company's meter may be wrong.

Yours, &c.,
Ed. C. de Segundo,
Assoc.M.Inst.C.E.

16th June, 1890.

PROTECTION IN ITALY.

To the Editor of "Industries."

Sir,—I have been greatly struck with the remarkable facts contained in your recent article on engineering in Italy. It is not long ago that Italy was virtually wholly dependent upon other other countries for its machinery. Yet by the very simple expedient of putting on protective duties the Government have succeeded in fostering a new industry, which appears to be meeting with the utmost success, notwithstanding the difficulty which had to be met in connection with the scarcity of raw materials. That this state of matters is bad for engineers and machinists in this country goes without saying. There are some who would be prepared to go further and assert that it is bad for the Italians, but though I am aware that a large proportion of the British public professes to believe in this as a general principle, I fail to see how it can be applied to the particular case in point. The Italians have got new works, fresh employment for their population, and money is now being spent at home which would otherwise have gone to us, to the Germans, Austrians, French, and Belgians. With such a result they have every reason to be satisfied.

Yours, &c.,
Tariff.

London, 15th June, 1890.

THE WOLSELEY SHEEP SHEARING MACHINES.

To the Editor of "Industries."

Sir,—With regard to the paragraph in your issue of yesterday, reflecting upon an experiment made at Stargard, Pomerania, with this company's machine shears, permit to say that the facts, as stated, are incorrect in some particulars, and greatly exaggerated in other respects, and to add that the succeeding exhibition given at the Strasburg Alsace Show was a perfect success, as the accompanying copy of our agent's letter, dated the 5th inst., will prove.

Yours faithfully,
H. E. McLeod,
Secretary,
Wolseley Sheep Shearing Machine Company, Limited.

Crown Court, Old Broad Street,
London, E.C., 14th June, 1890.

"Strasburg, Alsace,
"To the Secretary, "5th June, 1890.
"Wolseley S. S. M. Co., Ld.,
"Crown Court,
"Old Broad Street.

"Dear Sir,

"I beg to inform you that I am at present at this place with Langford, who occupies about 6 to 6½ or 7 minutes in shearing each sheep. The people are *very much* satisfied. I have excluded all Rambouillet sheep hitherto, but shall perhaps begin shearing a few to-morrow. There have been present a number of large sheep farmers at our shed, and all of them have a very good opinion of your machines.

"Yours very truly,
"(Signed) F. C. Jenkins."

Reviews.

American Railroad Bridges. By Theodore Cooper. New York: Engineering News Publishing Company.

This is a reprint, from the *Transactions of the American Society of Civil Engineers*, of a paper recently contributed by the author. The work commences with a brief historical review of American bridge building, beginning with "The Great Bridge," constructed in 1660 across the Charles River between Old Cambridge and Brighton, and ending with the Poughkeepsie Bridge, recently completed. The author then proceeds to consider the designing and proportioning of American bridges, the strength of materials and parts of skeleton structures, the manufacture of bridges and their erection, typical American railroad bridges and their relative merits, the number and kinds of bridges in the United States, and, finally, bridge failures. The author gives particulars of the train loads now assumed in America in designing bridges, and demonstrates the fallacy of the old method of employing equivalent uniform loads in proportioning structures. In view of the adverse criticism to which American bridges have been subjected in this country, part of Mr. Cooper's work is naturally a defence of the methods of construction adopted in the United States, and, on the whole, we think he makes out a very fair case as far as the engineers and contractors are concerned. Much has been made in some of our technical journals of the numerous failures of bridges which have occurred on American railways, but the author alleges that the data in regard to these failures have been magnified and distorted, and that the fact that the majority occurred with old and defective wooden bridges is ignored. There is not much consolation in this for the travelling public, who run the risk of mangling, drowning, or burning, or an unhappy combination of all three, whenever they cross such erections, but the fault lies with the railway companies and not with the present system of bridge design. Of 265 failures recorded as occurring during the ten years ending January 1st, 1889, only 38 bridges are known to have been of iron. It is well known that the loads per axle carried on American lines have been continually on the increase, while the bridges over which they run have not been proportionately strengthened or renewed; under such circumstances accidents were inevitable, but it is unfair to lay the blame for them on the system of pin connections. Mr. Cooper states that, with a few exceptions, "the iron railroad bridges of the United States for spans over 100ft., amounting to about 7,000 spans, aggregating 210 miles in length, are of the pin-connecting type." "The American people," he continues, "are of too practical a character to have built this quantity of bridges of a peculiar type, with the knowledge of other forms in use, both here and in European countries, and, after thirty years' experience in their use, to still adhere to them, if their merits were not strong and positive ones." At the same time the author admits the evils of the competitive system, which, to give the best results, should be "supplemented by the independent judgment of the practical bridge engineer."

In an appendix an interesting abstract of recent tests on full-size bridge members is given, while various types of bridges, some of them very curious, are illustrated in a series of folding plates, well executed. Altogether Mr. Cooper's book is a welcome addition to the literature of its subject, in which the author appears to be thoroughly at home.

Losses in Gold Amalgamation, with Notes on the Concentration of Gold and Silver Ores. By W. M'Dermott and P. W. Duffield. London: E. & F. N. Spon. 1890.

The recent gold discoveries in South Africa, and the revival in the gold-mining industry, have given rise to a number of treatises dealing with the extraction of gold from its ores. The latest addition to the list is an unpretentious work of 98 pages, in which Messrs. M'Dermott and Duffield record the results of a wide experience. Unlike recent works on gold, it is not made up of mere extracts from books, but bears internal evidence of being the work of two shrewd practitioners thoroughly at home with the minutest details of their profession. The aim of the book is not to give detailed descriptions of processes and machinery, but to present to directors of mining companies useful knowledge on the principles that are too often ignored by untrained mine managers. The authors warn directors not to listen to the specious promises of inventors of new processes, nor to plunge their shareholders into experiments which, in most cases, result in nothing but needless expense. The proper place for experiments is not in a new enterprise, but at a mine already as successful as known processes can render it, and too often what appear to be new processes and machinery are nothing but old contrivances and plausible theories long since exploded among practical men. Consequently, the authors confine their attention to modifications of approved processes. Most of their examples are drawn from the United States, for although the credit of scientific concentration of ores is due to the Germans, the working of gold ores is practised in Germany in a very limited degree. In the United States, the chief improvements on German methods are direct coarse stamping and classifying over jigs and slime machinery, and direct fine stamping over improved slime working machinery without sizing. The Cornish methods are not considered, for, being ill-adapted for good work on tin and copper ores, they are out of the question for gold ores.

The loss of gold in copper-plate amalgamation is shown to be much less than many inventors of new processes believe. In modern mills the tailings assay not more than ¼dwt. to 1½dwt. per ton. The concentration of gold and silver ores by a direct process, without sizing, after fine crushing by stamps, has become the established process for American ores, and, when properly conducted, leaves nothing to be desired. The authors

Digitized by Google

prefer steam stamps and hydraulic sizing to rolls and screens. They advocate the use of stamps for hard rock, and that of the Huntington mill for softer ores and for regrinding tailings. For combined gold and silver ores concentration is effected either by dry stamping, roasting, and pan amalgamation, or by coarser crushing, roasting in Stetefeldt furnaces, and double-leaching by the Russell process. When the ores contain much gold and but little base metals, roasting is avoided, and copper plates and concentration, or concentration and pan amalgamation, is used. The authors note a curious instance of successful roasting of a gold and silver ore, which is very free from base metals, at the Dickens-Custer mine in Idaho. The ore, consisting of quartz and calcite carrying free gold, native silver, brittle silver ore, and a minute quantity of base metal, yields 90 per cent. of the silver and 85 per cent. of the gold. The unusual freedom from base mineral probably accounts for the high proportion of gold extracted after roasting. For the treatment of ores in which the sulphides are extremely rich, double concentration should be employed. As a rule, it is assumed that if two Frue vanners are placed to five stamps, the mineral then escaping is too fine for concentration. Such is not the case. The loss is not a necessary but an accidental one, and can be reduced by a second treatment.

We can cordially recommend this book. To engineers engaged in the concentration of ores it will be of the greatest value. It is written in faultless literary style, and, were it not for the somewhat unsystematic arrangement of the material, and for the absence of an index, would deserve unqualified praise.

LOCKWOOD'S BUILDERS AND CONTRACTORS' PRICE BOOK, 1890.

This price book appears in a remodelled and enlarged form in the edition for the present year, and has much to commend it. As stated in the preface, recent improved methods of construction and every special feature of modern building, such as ventilation, sanitary appliances, and electric lighting, have been fully dealt with, and the book generally has been brought up to date. Under the different headings the "Memoranda" will be found interesting and of practical utility. They are a decided step in advance, and some of them are more to the purpose than in any previous edition, or, indeed, as far as we are aware, than in any other published builders' price book. The memoranda on roadmaking, concrete, Portland cement, bricklayer, and terra cotta are all good. A very full list of British building stones will be found, together with some of the principal French stones. Notice is taken of the beautiful Devonshire marbles, which have an increasing reputation. The appendix contains, besides Acts of Parliament, &c., the regulations issued by the London County Council and other public bodies, and also the rules adopted by the Phœnix Fire Office with regard to electric lighting. Ample information is given as to the "measurement" of work, and the prices should prove, with good judgment, a satisfactory guide. Exception may be taken, here and there, to a few of the prices: for instance, those for well sinking below 30ft. are low. However, as before stated, this book is a very useful one, and should find a place in every English office connected with the building and engineering professions.

AID BOOK TO ENGINEERING ENTERPRISE. By Ewing Matheson. Second Edition. London: E. & F. N. SPON. 1889.

When a book attains to the honour of a second edition, the work of the critic becomes almost superfluous in so far as practical results are concerned. Mr. Matheson's work, now before us, is in this happy position. The first edition was published in two separate parts, which have now been combined in one volume. To the first part a chapter on mining enterprises has been added, while the chapter on the manufacture and uses of steel has been re-written and extended; besides this some of the modern applications of electricity are referred to. The character of the information contained in these additions is, of course, much the same as in other parts of the work, of a distinctly practical nature. Engineers and contractors of experience might be inclined to complain that much of the information given is too general and commonplace, and that they knew it all before. For such, however, Mr. Matheson does not profess to cater.

We notice that, in connection with the use of steel, Mr. Matheson writes, p. 508, "For railway axles, ... steel of about 28 tons is required." As a matter of fact, a very much higher tensile strength than this is often specified; for instance, the proposed railway Clearing House standard specification for the construction of 8 or 10 tons private owners' waggons, to work upon the lines of the railway companies, states that "each axle must be guaranteed to stand a tensile strain of not less than 35 tons per square inch, with 20 per cent. elongation in ten inches." Among the modern applications of electricity to which Mr. Matheson refers, electric welding finds a place, as well as the transmission of power.

The work is now so well known that it is unnecessary to enter into further details.

THE GREAT TOWER FOR LONDON.

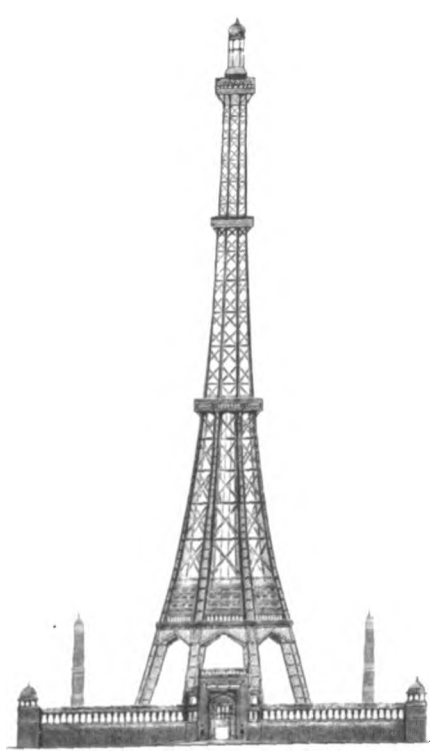

FIG. 1.—FIRST PRIZE.

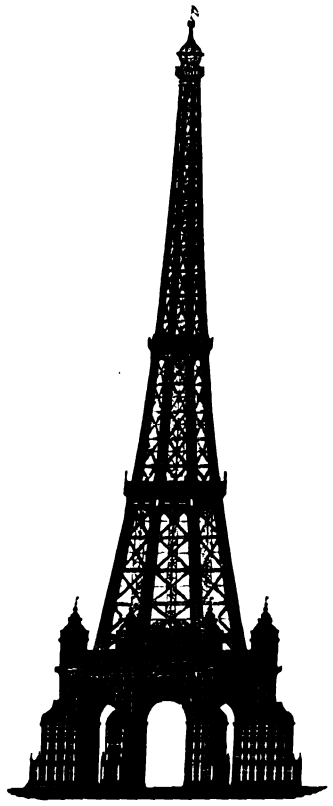

FIG. 2.—SECOND PRIZE.

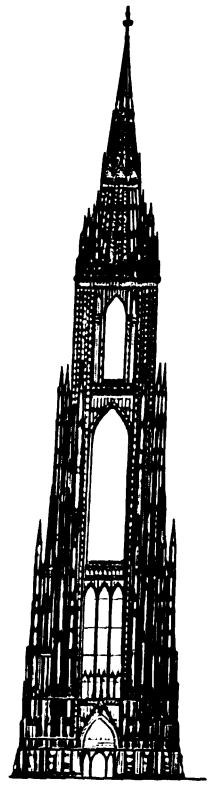

FIG. 3.—HONOURABLE MENTION.

THE GREAT TOWER FOR LONDON.

OUR readers will recollect that in our issue of the 9th ult. we published, in a two-page supplement, twenty of the sixty-eight designs for the Great Tower for London, sent in to the Tower Company, Limited, in response to their invitation. We remarked at the time that it would be invidious to make any comment until the jurors had given their decision. This decision has now being given, and we publish the Jurors' Report herewith. It may be seen that the three designs mentioned in the Report are Figs. 8, 13, and 12, on our two-page supplement, which we republish above as Figs. 1, 2, and 3. The first prize of 500 guineas has been awarded to the design shown in Fig. 1, and sent in by Mr. A. D. Stewart, M.Inst.C.E., 2, Queen's Square Place, London, W.; Mr. J. M. Maclaren, and Mr. W. Dunn, A.R.I.B.A., both of 21, King William Street, Strand, London, W.C. The design is for a tower 1,200ft. in height, having an octagonal skeleton 300ft. in diameter at base. The tower is constructed of steel throughout, and fitted with steam lifts to the top. The second prize of 250 guineas has been given to the design shown in Fig 2, and forwarded by Mr. John J. Webster, M.Inst.C.E., and Mr. J. W. Haigh, both of 67, Lord Street, Liverpool. This design represents an octagonal steel tower 1,300ft. high, standing on a base 470ft. in diameter. Hydraulic lifts are used, and the lower part of the tower and upper platforms are provided with buildings for residential and other purposes. The design shown in Fig. 3 has received honourable mention from the Jurors, and was sent in by Mr. Max am Ende, 5, Victoria Street, London, S.W. The design is for a tower 1,550ft. in height, of Gothic design, and constructed entirely of steel. The platform at 1,000ft. level is treated as the principal one. The lifts involve a train of carriages moving upwards between vertical guides, while a driving carriage below the train runs upon a spiral railway having a developed gradient of 1 in 5½. These spiral railway lifts may be placed in each of the four main columns. The competition was open to all competitors, and as stated in the Jurors' Report, the designs sent "were of very varying merit," and were disappointing as a whole, "there being no single design which they could recommend as it stands for execution."

REPORT OF THE JURORS.

GENTLEMEN,—Having completed our investigation of the competitive designs for the proposed Tower, we now submit our report. Invitations to compete were advertised on the 23rd October, 1889, and 68 designs were sent in. We met to consider these designs for the first time on the 15th March last. Every drawing has been carefully examined by the majority of the committee repeatedly, and whilst on exhibition at the Drapers' Hall (where the fullest opportunity was afforded of comparing the respective designs), we devoted an entire day there to the work, and throughout have given the most detailed consideration to the question before coming to a final decision as to the award of prizes. The designs were of very varying merit, and, although there were good points about many of them, we must confess to a feeling of disappointment on the whole as to the result of the competition, there being no single design which we could recommend as it stands for execution. In justice to the competitors it must be remembered, however, that the existence of the Eiffel Tower, and the desire to avoid imitations, necessarily considerably enhanced the difficulties of the problem, because in the Eiffel Tower the most natural and obvious way of combining economical construction and suitable architectural effect had already been appropriated. As a result some of the designs submitted were wildly eccentric or extravagant, whilst others were marked by an entire absence of architectural merit. We found little difficulty in eliminating the larger proportion of the designs, but the final award was not arrived at without repeated and prolonged consideration. Confining ourselves to the designs properly worked out by competent men, we found that in some cases the chief consideration had been given to economical construction and in others to architectural effect. In other words, some designers approached the problem from the point of view that the main thing was to get 1,200ft. above the ground with a form of tower which, having a fairly good outline, was specially adapted to resist wind pressure and other stresses with the minimum weight of steel, while others adopted the opposite view—namely, that the primary object was to get the best architectural effect without special regard to economy in construction or general practicability. In comparing the designs, we endeavoured to do the competitors the justice of judging of the merit of their work from the point of view adopted by themselves, and we also gave weight to the amount of time and care which had been devoted to the elaboration of the designs and calculation of stresses and estimates.

After very careful consideration we have decided to award the prizes as follow:—First prize (500 guineas), to Messrs. A. D. Stewart, J. M. Maclaren, & W. Dunn, of 21, King William Street, Strand, W.C., joint authors of design No. 37; second prize (250 guineas), to Messrs. J. J. Webster & J. W. Haigh, of 67, Lord Street, Liverpool, joint authors of design No. 51.

It is unnecessary for us to set forth the reasons of our decision in detail or to classify in the order of merit designs for which no prizes are available, but the Committee desire to state that they consider the design No. 50, by Mr. Max am Ende, deserves honourable mention.

We are, Gentlemen,
Your obedient servants,
E. H. CARBUTT (Chairman).
FREDERICK BRAMWELL.

THE BOARD OF TRADE AND ELECTRIC LIGHTING.*

(*Continued from page 547.*)

NATURE AND MODE OF SUPPLY.—In the old Orders two systems were mentioned, viz., the "parallel system," and the "*series system*," meaning constant-pressure and constant-current systems respectively. Now no system is specified, except that it must be one approved by the Board of Trade. A new sub-section was added to this last year at the instance of the telephone companies, by agreement with the promoters, for the protection of the telephone circuits against interference by induction or otherwise, they being naturally rather alarmed at the proposed general use of alternating currents. In the "Works" clauses, I need only mention that in the new model it is proposed to give powers for the construction of "street" boxes in place of "distributing" boxes. The special power taken is necessary, I believe, because these boxes come up to, and may come above, the surface of the ground. Also, that the prohibition of overhead wires, introduced last year, is inserted in the new model for companies, with the alteration that the time allowed for removal of existing overhead wires is reduced to one year. But they may be erected or continued in use with the consent of the local authority. This prohibitory section is based upon, and really does not go beyond, section 14 of the Act of 1882. The "*Compulsory Works*" clauses provide generally that the undertakers shall do something substantial towards carrying out their undertaking within a specified time, under penalties of fine or revocation of the Orders. The Board of Trade, however, must, in the case of a company, be moved to exercise its power of revocation by the local authority, except in the last model, where this has been altered; while in the case of a local authority being the undertakers, the Board of Trade has not hitherto, so far as I am aware, thought fit to exercise its power of revocation for non-performance of works within the required time, probably considering the plea that the practical knowledge and experience of electrical distribution was not sufficient to justify any expenditure of public funds, a valid one. This plea, however, is obviously daily diminishing in force. In nearly all Orders the specified time within which mains have to be laid in certain streets is two years. It is three years in the Birmingham Order of last year, but all streets within the area are included. The Liverpool Order is also an exception. In the old Orders two years was also the period that had to elapse before any supply could be requisitioned in other streets, and six months more is allowed to comply with the requisition. In last year's London Orders and the new forms, however, supply can be requisitioned after eighteen months, with six months for compliance; so that persons in streets not scheduled can get a supply at the same time as those in scheduled streets. Also, in the recent Orders, as already mentioned, supply can be requisitioned for any part of the area included in the Order; whereas in the old Orders it could only be requisitioned for the A district. There is a slight variation, too, in wording, which may be important, viz.: whereas in the old Orders mains were to be laid *in* every street, now it is *throughout* every street. The requisition to lay distributing mains in any street has to be signed by a number of persons, which number is a very variable quantity in different Orders. Thus in the old Orders of 1883 it was two or more owners or occupiers in the case of an Order given to a company or person, and the owners or occupiers of not less than one-fourth of the premises in the street in the case of a local authority. In the Chelsea Order of 1886 it was six or more owners or occupiers. Last year the Board of Trade reverted to the former practice both in the case of companies and local authorities, except in the Birmingham and Liverpool Orders, where no power of requisitioning is given to owners. These two Orders are very exceptional in respect of these clauses. This year, in the model forms, which are not intended to apply to London, it is proposed to follow the precedent of the Chelsea Order, and to require six signatures to a requisition, the number being the same both for local authority and company Orders. After the requisition clause follows a long clause intended to provide that the undertakers shall, if they so require, be guaranteed by the persons making the requisition a return for their outlay in laying the requisite mains of 20 per cent. per annum for three years in the old Orders, two years in the London Orders, and again three years in the new model Orders.

After these "Compulsory Works" clauses come a few clauses headed "Maps," and then, in the old Orders, "Regulations as to Supply on the Parallel System." These regulations are not inserted in any of the recent Orders, but are issued separately with the Safety Regulations. Then we come to some clauses headed "Testing" in all Orders up to this year; but in the new models an improved arrangement has been followed, and "Supply" comes next to "Works," which certainly seems a more logical sequence; also, the clauses applying to the appointment and duties of electric inspectors are now put under a separate heading. Taking these clauses first, the appointment of electric inspectors is vested, in the case of all Orders to companies, except the London Orders, in the local authority; in the London Orders it is vested in the County Council; and in all existing local authority Orders in a court of summary jurisdiction, moved either by a consumer or by the undertakers themselves. In the new model this appointment is vested in the Board of Trade. In case of the local authority not appointing an inspector, or imperfectly attending to inspectional duties, there is a provision in all company Orders for appointment, in some cases by a magistrate, in others by the Board of Trade. In the new model Orders a clause has been added specifically stating that the Board of Trade may appoint an inspector for the purposes of any inquiry on an accident or as to safety. I think it is obvious that the Board of Trade has in any case, whether expressed in the Order or not, the right to make inquiry as regards safety. All local inspectors are to be paid by the local authority, or County Council for London; but fees may be charged by means of which part, at any rate, of the cost of inspection will be recouped. Inspectors may be appointed from time to time for particular services, or the appointment may be continuous. It is rather difficult to see how this matter will work in small towns where there may be no resident electrician unconnected with the undertakers, or, at any rate, none who would care to undertake the job for such remuneration as could be offered without unduly increasing the cost of the supply, since the expenses of inspection must in one way or another be borne by the consumers. Probably one electrician will secure the appointment for several towns not very far apart, and reside in a convenient locality for his district. It will be something like the birth of a new species; and some follower of Darwin will in the next century write an exhaustive monograph on the genesis of the electric inspector, showing how he came to differentiate from ordinary mortals, how he gradually acquired an extra sense warning him against high pressure, &c. The duties of electric inspectors are clearly defined in the new model Orders, as follows:—

"The duties of an electric inspector under this Order shall be as follows: (*a*) The inspection and testing, periodically and in special cases, of the undertakers' electric lines and works and the supply of energy given by them; (*b*) The certifying and examination of meters; and, (*c*) Such other duties in relation to the undertaking as may be required of him under the provisions of this Order or of any regulations under this Order."

The next clauses in the new models are headed "Testing and Inspection;" and this is an improvement on the old heading of "Testing" alone, since it is obvious that in the case of a network of mains a good deal may be found out by inspection that could hardly be arrived at by testing. These clauses have been greatly altered, and I would especially draw attention to a new clause—"40. An electric inspector, if and when required to do so by any consumer, shall from time to time, on payment by the consumer of the prescribed fee, test the variation of electric pressure at the consumer's terminals, or make such other inspection and testing of the service lines, apparatus, and works of the undertakers upon the consumer's premises as may be necessary for the purpose of determining whether the undertakers have complied with the provisions of this Order, and the regulations and conditions subject to which they are for the time being authorised to supply energy;" which is, I think, very practical and may have important results. This clause takes the place of the following in the existing Orders:—"35. Every electric inspector, if and when required to do so by any person supplied with energy by the undertakers, shall from time to time test for insulation and conductivity any service lines by which such energy is supplied and the efficiency of any joints in such service lines, and make such other tests in relation to such service lines as may from time to time be approved of by the Board of Trade." In all Orders there is a clause providing for the establishment of testing stations at various points in the area, either by the undertakers or by the local authority. I am not aware that any such testing stations have yet been established; but I believe that in several districts in London they are to be established for one position at any rate—at the office of the local authority. The practical use of these testing stations is obviously to obtain a record of the variations of pressure at different points in the system, and of the duration of any abnormal pressure or stoppage of supply. The best solution appears to be to have a recording voltmeter at each station, which might be made in the shape of a pillar box; and possibly an indicating voltmeter exhibiting the pressure at any time would be a welcome addition. I consider that the production of a thoroughly trustworthy recording voltmeter is distinctly a desideratum for the improvement of electric supply. There appear to be very few such instruments in use at the present time. In all Orders I think there is reserved an appeal to the Board of Trade against any report of any electric inspector. It is to be hoped that this power will be used with discretion, as the electrical staff of the Board of Trade is strictly limited at present.

Now, taking the "Supply" clauses, we have, first, that any owner or occupier of premises situated within a certain distance of any district main can demand a supply. This distance is in the 1883 Orders 25 yards; in the London Orders and the new forms 50 yards. He may be required, however, to pay the cost of service lines beyond a distance of 30ft. in the old, 60ft. in the London and new model Orders. He must name a maximum current in the old Orders, or a maximum power in the new, so that the proper size of service lines may be laid, and this maximum must not be larger than what may reasonably be expected to be the consumption on the premises; and if afterwards he wishes to go beyond the declared maximum, he must be prepared to pay for any alteration of service lines or apparatus thereby rendered necessary. The person requiring a supply must also be prepared to make a contract to take and pay for a supply for at least two years of sufficient amount to pay 20 per cent. on the outlay incurred by the undertakers. Then follow provisoes as regards security for payment, prohibition of improper use of the supply, and a very important one added last year. The "Price" clauses have been considerably affected by the supply being now considered a supply of energy, and not, as formerly, of electricity. I will give the first clause as it stood in the old Orders and in the London Orders:—"31. The undertakers may charge for electricity supplied by them to any consumer (otherwise than by agreement)—(1) By the quantity of energy contained in such supply; or (2) by the actual quantity of electricity so supplied; or, unless the Board of Trade from time to time otherwise direct, (3) by the number of hours during which the supply of electricity is actually used by such consumer, and the maximum current with which he is for the time being entitled to be supplied." "50. The undertakers may charge for energy supplied by them to any ordinary consumer (otherwise than by agreement)—(1) By the actual quantity of energy so supplied; or (2) by the electrical quantity contained in such supply; or, unless the Board of Trade from time to time otherwise direct, (3) by the number of hours during which the supply of energy is actually used by such consumer, and the maximum power with which he is for the time being entitled to be supplied." In the new models method (3) has been altered as follows:—"32. The undertakers may charge for energy supplied by them to any ordinary consumer (otherwise than by agreement)—(1) By the actual amount of energy so supplied; or, (2) by the electrical quantity contained in such supply; or (3) by such other method as may for the time being be approved by the Board of Trade." The reason for this is that the old method (3) is decidedly wasteful, and, if generally adopted, would lead to far more energy than was necessary being supplied from central stations. Except in special cases, such as lighting of shops and business premises, it should be noted that the consumers are free to make any agreement they prefer as to the price to be charged and the method, but they have a right to be charged in accordance with methods (1) or (2), and the undertakers are always bound by the undue preference clause.

The meter clauses have hardly been altered at all, and it is, in my opinion, proof of the very great care and acumen with which these clauses were originally drawn—so far back as the year 1883—that no really satisfactory improvement has yet been proposed. These clauses will repay very attentive study. They are sometimes looked upon as stumbling-blocks, and it is said that they are unintelligible, and that they won't work; but I am afraid that these difficulties are rather due to want of study and defects of meters than to the clauses themselves. Any number and description of meters may be used both by consumer and undertakers, but only one meter is to be used for ascertaining the value of the supply. This is to be a meter certified by an electric inspector appointed under the Order. Note that it cannot be certified by anyone else. The inspector must certify three things: (1st) That the meter is of some construction and pattern approved by the Board of Trade; (2nd) that it has been fixed and connected to the service lines in some manner approved by the Board of Trade, which must, therefore, in approving any pattern of meter, prescribe in what way it is to be fixed and connected to the service lines; (3rd) that it is a correct meter; and in making this last declaration the inspector, in my opinion, may reasonably take account of and be guided by any mark or certificate attached to the meter showing that it has been thoroughly tested and found sufficiently accurate to be pronounced a correct meter in some standardising laboratory, or he may himself carry out the necessary tests in a laboratory. It is obvious that he cannot thoroughly test it in the consumer's cellar, and also that the words "a correct meter" cannot be held to be only applicable to a meter that was absolutely perfect throughout its range. The undertakers are to supply the consumer, either by purchase or hire, with a meter on demand, and procure its certification. No consumer is allowed to connect or disconnect the meter used for ascertaining the value of the supply without giving 48 hours' notice to the undertakers, under penalty. If this meter belongs to the consumer, he is to keep it in proper order, but if it is hired from the undertakers they must maintain it, and in either case they may remove it for testing, all expenses connected with the removal being paid by the consumer if the meter turns out to be faulty, and by the undertakers if it is in proper order; and any other meter or apparatus placed by the undertakers upon the consumer's premises for the purpose of ascertaining or regulating the supply of energy must be of some construction and pattern and connected in a manner approved by the Board of Trade.

The only other point in the Orders of much electrical interest is the Price Schedule. In this the definition of the Board of Trade unit has remained unaltered, except the simplification of the wording. Last year there was, as you may remember, some agitation to have the amount of the unit increased tenfold. The point was referred to your Council, who did not recommend the alteration, and the Board of Trade very willingly left it as it was. Of course undertakers are at liberty to make agreements for a price per 10 units, provided that the charges do not exceed the rates laid down in this schedule. In the London Orders of last year there was added to the second section a proviso to enable the standard pressure on the mains to be taken into account in assessing the value of the supply where this pressure is a high pressure, and the energy is transformed; but in the new model this section has been much simplified by the introduction of a new term, viz., the declared pressure at the consumer's terminals, which it is proposed to deal with in the new regulations.

(*To be continued.*)

* Paper read by Major Cardew before the Institution of Electrical Engineers on the 17th ult.

THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

(*From our New York Correspondent.*)

(*Continued from page 572.*)

THE first paper read on the 21st of May was by Mr. Wilfrid H. Fleming, on "Electric Lighting in the Tropics." The chief difficulties experienced, said the writer, were due to the lack of skilled labour and the distance from the factory which was the base of operations. Electric lighting had met with much favour in the tropics, and the use of motors was likely to be equally popular. One of the attractions of electric lighting was the fact that the lamps could be started up at once, which was desirable on account of the brief twilight. It was necessary to import suitable poles, and in India it was important that the basis should be thoroughly creosoted as a protection against white ants. On account of the moist atmosphere, dust, and insects, it was found that a native could not properly care for more than twenty-five lamps per day. In station construction the rain gutters should be double the size allowed for in temperate climates. The building material most suitable depends upon the particular locality in question. The heat of the sun is so powerful that insulation of a proper character is essential, and unusual precautions should be observed against damage by lightning. In 1877 what was probably the first commercial arc lamp shown in India was used in the offices of the Bombay *Times*, since which date the demand for electric lighting in that country had steadily increased. The high price of coal, ranging from $8 to $50 per ton delivered, makes it important that the most economical engine should be used. On many West Indian sugar plantations, however, economy in this respect is not so essential, as owing to the large boiler capacity of the

Digitized by Google

mills the small proportion of steam is not missed. The machines used in the East Indies are of European manufacture, the Siemens, Gramme, Silvertown, and other well-known types. In the West Indies, South and Central America, they are generally of American make, and the market is quite important. In shipping machinery to the tropics it is imperative that every essential tool for construction should be included, also spare armatures, complete sets of arc lamp apparatus, duplicate parts of dynamos, brasses for the engine, tubes for the boiler, &c.

"Life and Efficiency of Arc Light Carbons" was the subject of a paper by Mr. Louis B. Marks. This investigation of carbon pencils was taken up at Cornell University for the reason that little or no increase in the efficiency of carbons had been witnessed since the inception of the business, and that with the practical perfection of lamps and dynamos the improvement in carbons was pre-eminently important. The carbons experimented upon were from five different American manufacturers. The subject was treated under the heads of structure, life, efficiency, candle-power, and observations of the arc and carbon points. The requirement of the low-tension system is a carbon that is hard, well plated, and a good conductor, the latter being most important. In the high-tension system, hardness and conductivity are of secondary importance. There is a tendency to flame and burn unsteadily when a hard carbon is used in this system, and a softer one becomes necessary. One company makes "forced" carbons in which the material is forced through a die, while another makes only moulded pencils. Twelve photographs were shown, in which the appearance of the carbons was manifest. They were obtained by mounting thin transverse sections, and subjecting them to a magnifying power of from 40 to 80 diameters. They showed a marked difference in structure between the forced and moulded carbons. In the high-tension pencil of one brand the structure was a loose one, while in the low-tension carbon of the same group the structure was dense and homogeneous, the grains being much smaller, and under the microscope having a more metallic lustre. In one brand, the moulded carbons are made under a greater pressure, for use in low-tension systems.

The life tests showed that if a carbon is burned with a small current, its life will be long at a sacrifice of light-giving properties. On the other hand, if a large current is used, there may be a gain in efficiency at a sacrifice of life. The question, then, arises, What is the proper current to use? The high-tension carbons were designed for a current of 10, and the low-tension for 20 amperes. In the life tests, a Thomson lamp was used for high-tension runs, the current constant at 10 amperes and 50 volts. For low tension a Weston lamp was used. It has been stated that "with carbons of the same *hardness* and length, but having different diameters, the larger will undoubtedly outlive the smaller. Of carbons of the same *diameter* and length, but differing in hardness, the harder will outlive the softer." (G. W. Parker.) This statement presupposes that the conductivity of the carbon is directly dependent on the hardness or softness of the pencil. In order to examine the relation between diameter, resistance, and mortality of a pencil, six sets varying in diameter from $\frac{1}{8}$in. to $1\frac{1}{8}$in. were carefully weighed, their resistances measured, and the pencils burned with a constant current of 10 amperes and 50 volts from a Gramme dynamo. The diameters and resistances of the upper and lower carbons were practically equal. The results of an hour's run showed that the life of a carbon varies *directly* with its *diameter*, and *inversely* with its *resistance*. This law holds only for homogeneous carbons of the same manufacture, type, and structure, and for constant current and voltage. Taking the $\frac{1}{8}$in. and 1in. pencils as standards, and calculating the mortality of the other carbons, it appears that the calculated life throughout the series is larger than the actual when the $\frac{1}{8}$in. carbon is taken as a standard, and smaller when the 1in. pencil is made the basis of calculation. While every precaution was taken to avoid discrepancies, it is clear that from the nature of the substance, and the difficulty of maintaining constant conditions, errors are apt to creep into the work. The results obtained, as well as later determinations, undoubtedly point to the existence of such a law as has been quoted. Experiments were also made to determine the curve for current and mortality of the pencil with constant voltage, also with constant current and varying voltage. No experiments were made upon arc-light carbons fed by alternating currents, but an investigation of the relative loss of the positive and negative pencils showed that the positive may burn away as fast as the negative, or may waste more than three and a half times as quickly. The causes that influence the relative life of pencils of the same diameter lie chiefly in the difference in the resistance of the carbons and the variations of potential difference.

In the efficiency tests, the horizontal efficiency was very small compared with the maximum; and it was shown that the relatively high efficiency in a *forced high tension* carbon is obtained only at the expense of life; that a moulded carbon is, generally speaking, superior to a *forced* for high tension, and *vice versâ* for low tension. While the life of a copper-plated carbon is greater than that of an unplated carbon of the same diameter and type, the mean spherical efficiency appears to be the same for both. No positive explanation of this phenomenon has yet been given, but it appears that the actual amount of *combustion* in both cases is the same, while the *disintegration* caused by the passage of the current is greater in the case of the unplated carbon. In the candle-power measurements it appeared that the efficiency of low-tension carbons and specially *moulded* low-pressure pencils is comparatively small. While the efficiencies of moulded high-tension carbons were as high as ·953 and ·888 watts per spherical candle, or 783 and 840 candles per electrical horse-power expended in the lamp, the efficiencies of low-tension pencils of nearly the same diameter as the high are as small as 1·255 and 1·612 watts per candle, or 594 and 502 candles per electrical horse-power. Gerard's law will not hold for calculating the mean spherical efficiency from the horizontal and the maximum. But for approximations a similar law holds—*i.e.*,

$$\textit{Spherical efficiency} = \tfrac{1}{4}\ \textit{horizontal} + \tfrac{3}{4}\ \textit{maximum}.$$

Observations of the arc and carbon points showed that with a given potential difference between the terminals of the lamp the length of the arc depended on the current flowing, and increased as the current became greater. If the current be kept constant, the length of the arc increases with the P.D. No direct relation seems to exist between the length of the arc, and the current, and P.D. In this case the length of the arc with constant potential increased very rapidly as the current was changed from 6 to 9 amperes, and then gained slowly from 9 to 13 amperes. The nature of the change was somewhat different in the constant current runs, the arc increasing more nearly as the square of the voltage. It was found that the carbon points assumed particular shapes, depending upon the current and P.D. used. With 5 amperes there was a tendency to form a "mushroom" on the lower carbon; with 10 amperes, this tendency is not at all marked, and at 15, almost inappreciable. Most of the irregularities in the action of arc lamps probably result more from unsuitable carbons, than from defects in lamp mechanism or changes in the strength of current, or P.D. in the line. The remedy lies with the carbon manufacturer, who should be able to produce a carbon especially adapted for the needs of any particular system.

(To be continued.)

THE PHYSICAL SOCIETY.

At the meeting of this Society on the 6th inst., Professor W. E. Ayrton, F.R.S., President, in the chair, Mr. H. Tomlinson, F.R.S., read a paper on "The Effect of Change of Temperature on the Villari Critical Points of Iron." This, he said, was a continuation of the paper he read before the Society on the 21st March, and the method employed was the same as then described (see *Phil. Mag.*, Vol. XXVIII., page 394). Since then, however, he has made experiments at various temperatures up to 285° C., the temperature being measured by the resistance of a platinum wire, whose temperature coefficient was carefully determined. The following table shows some of the results obtained with a well-annealed iron wire, 1mm. in diameter, which had been repeatedly heated up to 300° C., and cooled to the temperature of the room until the temporary permeability with various loads attained constant values at both temperatures:—

Magnetising Force in C.G.S. Units.	Load in Kilogrammes for which Permeability is the same as for Unloaded Wire at Temperature				
	12° C.	76° C.	167° C.	244° C.	285° C.
2·84	4·7	5·0	5·3 and 12	5·7 and 10	None
3·70	2·5	3·2	3·6	4·2 and 11·5	4·7 and 9·9
4·8	1·8	2·5	2·7	—	3·1 and 12·3
7·69	None	None	None	None	None
10·40	,,	,,	,,	,,	,,
15·32	,,	,,	,,	,,	,,

Curves from which these numbers were obtained are given in the paper, and in these load in kilogrammes and percentage change of temporary permeability are plotted. From the curves and table it will be seen that if the first points in which the curves cut the load line be considered, then, at all temperatures, the Villari values increase as the load decreases. If, however, the second points be taken, the critical values increase both with load and temperature. In both cases the Villari value is increased by rise of temperature. From the curves it follows that rise of temperature reduces the total variation of permeability that can be produced by loading. A table showing the temporary permeability of the unloaded wire at the various temperatures accompanied the paper.

A paper on "The Diurnal Variations of the Magnet at Kew," by Messrs. W. G. Robson and S. W. J. Smith, was communicated by Professor Rücker. In some preliminary remarks, the Professor pointed out the great advisability of having the results of magnetic observations at various observatories reduced and published in the same manner, and for the same periods. In order that this may be effected, the methods of reduction must be reliable, but not very elaborate. The Greenwich plan is too laborious to be generally adopted, but the method suggested by Dr. Wild (Rep. Brit. Assoc. 1885, page 78), in which the mean diurnal variation is obtained from measurements on five quiet days in each month, is feasible. With a view to further testing the reliability of this method the work described in the paper was undertaken. Mr. Whipple had made a comparison of the two methods for the years 1870-71-72, with the result shown in the following table:—

$K_s - K_w = 0{\cdot}7'$ (minutes of arc)
$G - K_s = 1{\cdot}2'$,, ,,
$G - K_w = 1{\cdot}6'$,, ,,

where K_s is the mean diurnal range at Kew as obtained by Sabine's method; K_w the mean diurnal range at Kew as obtained by Wild's method; and G the mean diurnal range at Greenwich by the Greenwich method. He also found that the mean hourly differences followed some definite law. The authors undertook the reduction of the Kew observations according to Wild's method for the years 1883 and 1886-87; the first was chosen as being a year of maximum sun spots. The results give:—

1883 ... $G - K_w$ = 1·5′
1886 ... ditto = 1·2′
1887 ... ditto = 1·9′

There is thus a difference of nearly two minutes in the variations at the two places, and this cannot all be accounted for by the method of reduction. Another peculiarity is that the range, as calculated by Wild's method, is greater by about 0·5′ than that obtained by Greenwich method, although the latter includes days of moderate disturbance. The total range at both places has diminished by about 1·6′ between 1883 and 1887. The paper was accompanied by tables and curves plotted from the differences in the mean hourly readings at Greenwich and Kew for each of the above six years, and a marked similarity exists between all of them. The mean of the six curves differs in no case by more than 0·4′ from the curve of any year. It is thus possible to calculate the Greenwich values from the Kew numbers, and as these latter are published about two years sooner than the former this fact may be very important. Referring to the reduction of results, Professor Rücker said that the Stonyhurst observers and Professor Mascart were willing to adopt Wild's method; Falmouth, he hoped, would follow suit; and Greenwich had been asked to publish their results in both ways.

Mr. Whipple said that before recording instruments were available, and the numbers were obtained from separate experiments, the labour involved was considerable, and a single large disturbance or magnetic storm might vitiate the result of a whole year's work. Methods were therefore adopted to eliminate these disturbances. Of these, that used by Sabine may be particularly mentioned. Although declination records have now been obtained for a considerable number of years, the cause of the variations still remains unknown. They do not seem to be dependent on temperature or on astronomical facts. He considered it valuable to obtain magnetic data from different parts of the earth, but comparisons were only possible when all are published on the same plan. This, he hoped, would result from the efforts of Professors Rücker and Adams. When this is accomplished, the observations on magnetic force will need treatment; this work will be laborious, and the aid of volunteers like Messrs. Robson and Smith would be of great service.

Professor W. G. Adams said he was glad to see the satisfactory nature of the work which had just been brought before the Society. Usually the mass of figures to be dealt with was so large that the mere reduction was a great undertaking. If, however, the difference between results obtained by the Greenwich and Wild's method was not more than 0·4′, it may be possible to make out the causes of the variations from observations reduced on Wild's plan. He himself would put more faith in horizontal force observations, and wished they could be worked out by some ready method. He hoped the one adopted in America, of obtaining mean curves by photography, may prove satisfactory.

Professor Perry asked if a machine could not be made to do the work.

Digitized by Google

Mr. Whipple said such machines had been used by the Meteorological Office, but they were so elaborate and expensive that clerical work was just as cheap. The method of photographing mean curves had been tried at Kew, but it was open to the objection that accidental disturbances such as those produced by the movement of iron in the vicinity, and the approach of cabs, &c., were not eliminated.

Mr. Boys, referring to the use of integrators, said that for a harmonic analyser his disc-cylinder pattern was preferable to the ball-disc-cylinder integrators of J. Thompson, for it is much cheaper and has less inertia.

The President said the movement initiated by Professor Rücker would be of great service if it resulted in the numbers obtained at the various magnetic observatories being published in the same way. It was a great advantage to have such men, who were not attached to an observatory, to take up the subjects and suggest improvements. The heads of such Institutions were usually too much employed in making the necessary reductions to have time for devising improved methods. In his opinion greater freedom should be allowed to the chiefs of observatories, for it should be borne in mind that the object of observations is not to produce volumes of figures, but to increase our knowledge. Referring to the reduction of observations, he thought the voluntary services of senior physical students should be more generally accepted, and to this end he suggested that properly recommended persons should be allowed to spend some time in observatories as honorary assistants. This would be of great use to the students themselves and an advantage to the observatories, for the reduction of observations could then be expedited. As regards the accidental disturbances referred to by Mr. Whipple, he contended that regulations should be adopted to render them impossible.

Notes.

THE "HENRY."

It is to be hoped engineers will adopt the American suggestion, and call the practical unit of self-induction the "Henry. The name "Quad" is unsystematic, because all the other units are formed from men's names. It also has the still more important objection of implying some physical identity between self-induction and length. The only drawback to the name "Henry" is that it may be shortened into "Hen."

PUBLIC WORKS IN GREECE.

Fifty years back the Piræus was a small hamlet with 4,000 inhabitants, but it has developed rapidly, and is now prosperous, with a population of about 36,000. Flour and cotton mills, paper works, iron foundries, saw mills, and nail works have been established. It is proposed to dredge the bay, and, a larger supply of water being needed, artesian wells have been sunk at Phaleron. The water will be conveyed in iron pipes to reservoirs now being built for the purpose. Consul Dupuis states that the works of the cutting of the Corinth Canal, which were suspended for want of funds, will probably be shortly resumed by a new company.

AMERICAN COTTON.

Mr. Vice-Consul Robertson reports to the Foreign Office that the town of Savannah is making very rapid progress. It is not yet entitled to be classed among the manufacturing cities of the United States, but industries are springing up. Last year nearly all the exports increased. The value of the cotton was £4,923,312, as compared with £3,117,426 in 1888. This was due, first, to the exceptionally fine weather throughout the whole cotton belt for the growing and making of the staple; secondly, the increased acreage planted in cotton; and thirdly, the additional territory available to the Savannah market by the increased railway extension. The exportation of cotton seed continues to increase.

GRANTS FOR TECHNICAL EDUCATION.

The Committee of Council on Education have allocated for the financial year 1891-92 the sum of £5,000 for grants in aid of technical instruction given under the Technical Instruction Act. In a discussion on the subject in the House of Commons, Mr. Mundella remarked that there was not a canton in Switzerland that would not be ashamed of such a paltry provision for technical education. Mr. Goschen, however, explained that the smallness of the amount was the result of the comparatively small demand made by the local authorities, and that there was every disposition on the part of the Government to meet the full requirements of the Act. The grants in aid will not necessarily be equal to, and in no case will exceed, the amount contributed by the local authority out of the rates, and each grant will be computed, as far as possible, on the basis of the amount spent on subjects of technical instruction other than those for which the Science and Art Department gives aid. This arrangement we consider very good, as it will prevent waste of money and lavish expenditure, when at least one-half of the total amount is to be paid for by the localities. Grants from the Imperial Treasury are too often looked upon as gifts direct from heaven, and are spent in a most reckless manner, whereas when they are paid for directly by the localities the ratepayers generally look sharply after them.

POSTAL ARRANGEMENTS IN CHINA.

In Japan for some years past there has been a very perfect system of postal and telegraph service, which has done much to develop that country, but in China there is, as yet, no national postal service, and special arrangements have to be made by the foreign residents at each of the treaty ports. At Shanghai the chief foreign Powers have maintained post offices of their own, and in the other open ports were branches which were under the charge of the consular officers. This arrangement has not been found satisfactory, for the work of each office was not sufficient to justify a sufficient staff being kept, and complaints have been very numerous. Sir Robert Hart has for some years maintained a small postal service of his own in connection with the Customs, and he now suggests that he should take over all the foreign postal agencies at the various open ports and run them as branches of the Customs. Considering the trouble the present arrangements give to all concerned, and the very unsatisfactory results, we should think that the various parties interested will be only too glad to hand them over to Sir Robert Hart, who is certain to take care that his proposals will be efficiently carried out.

ANTI-FOREIGN FEELING IN BRAZIL.

It is somewhat curious to observe how often Republican forms of Government are more selfish and narrow than those of an autocratic or aristocratic form, and this has been strikingly shown under the new *régime* in Brazil. The Minister of Finance recently issued a decree relative to the more complete and reliable collection of statistics referring to finances, navigation, and commerce of Brazil, and in it he makes a bitter attack on the foreign merchants of the country. He states that credit establishments must be formed to make advances to producers and merchants, and that Brazilian houses must be established in the foreign markets, so that in this manner the monopoly of the exportation, which is exercised exclusively by foreign houses in Brazil, would cease to be affiliated to head offices situated in European and American markets, which indulge in speculation that has an arbitrary effect on prices. He states that while the formation of these houses in foreign markets must be due to private initiative, still the Government of the Republic may, through certain incentives, foster this initiative. There is also talk of creating a great national steamship line for transatlantic and coasting trade. Hitherto the province of Rio Grande do Sul has had an advantage over the others in respect to customs duties, but the Republican Government has determined to place all the States on the same footing from the 1st of July.

AUTOMATIC GAS RETORT.

The Brentford Gasworks at Southall have recently been utilised for a series of trials of the coking retorts devised by M. Coze, in which the coal is made to self-feed the retort, which is arranged in such a way that the angle of slope is always maintained. The coal remains still when put into the retort, but at the carbonised end the coke slides out upon being subjected to the slightest disturbance. The plant erected at Southall has been somewhat modified during the progress of the investigation by Messrs. Morris and Van Vestraut, and in its final form possesses several important advantages over the French process. The retorts are inclined at an angle of 30 deg. and charged by means of a telescopic shoot, which is thus enabled to reach each tier. A guide is attached to the lower end of the shoot, to control the velocity of the falling coal, and thus maintains an even distribution of the material over the bottom of the retort, while the coke slips uniformly out of the lower end at the slightest touch. A recent report speaks very favourably upon this modified form of automatic gas retort, and, from its obvious advantages of economy in working and construction, it seems likely that the new system will give gas companies great command over the carbonising department of their works in the event of future labour difficulties.

ROUMANIAN INDUSTRIES.

Three years ago a law came into force in Roumania, the object of which was to foster home industries; but though a good many undertakings have availed themselves of it, there has not been much progress, owing to smallness of capital and want of skilled labour. Among those which have got on are several tanneries, factories for making coarse cloth, two glass works, three paper mills, and a boot and shoe factory. Steam flour mills are flourishing and distilleries are in the same position. A new company has been formed for the manufacture of Portland cement at Ibraila, and another for working petroleum. Rope works have been successful.

PUBLIC WORKS AT KUSTENDJIE.

Mr. Vice-Consul Churchward, of Kustendjie, which is officially known as Constanza, states that now that the Roumanian Government has accepted a tender of the French Fives-Lille Company, for the construction of a commercial bridge across the Danube at Tchernavoda, it will probably bring further enterprises in its train in which British capital could be employed. When the bridge is finished harbour works will be required, as well as an extension of railways. Town improvements will follow, including water works, gas or electric light supply, and public granaries.

THE PHYSICAL FOUNDATION OF MUSIC.

At the Royal Institution, on Friday evening last, Professor Silvanus P. Thompson delivered a discourse on the above subject. The lecturer began by observing that experimenters had endeavoured to give physical expression to psychical sensation. The precise cause of the gratification the ear experienced by hearing a succession of notes whose vibrations had such relations to each other as to cause them to constitute a "scale," and form the basis of "melody," or by hearing the sound produced by some combinations and not by others, the examination of which is the object of "harmony," or by a note from one instrument rather than from another differing in "timbre," was difficult to locate. Sounding the middle C of the ordinary pianoforte scale with D produced dissonance, the reason being, according to Helmholtz, the formation of "beats." The unpleasant effect of the beats was at its maximum when they numbered 33 per second, diminishing when both more and fewer were produced. In this connection it must be remembered that Helmholtz considered the number of beats produced by any given pair of dissonant notes was equal to the difference of their respective numbers of vibrations per second. Thus, between the lowest C and D there was a difference of 4 vibrations per second, giving 4 beats, while the middle C and D gave 32 beats, and the top C and D 256 beats But this theory failed in some respects, and had to be supported by several sub-hypotheses, and was not borne out by the researches of König, who had made a special study of the matter. By using tuning forks for the production of the notes needed, König had at once procured pure tones (unattainable by the use of stretched strings), thus obtaining ing reliable data; and his conclusion was that the number of beats was equal to the remainder got by dividing the number of vibrations of one of the dissonant notes into that of the other, and, further, that the remainder need not be "positive." Besides the question of beats, there were other points in which König's experiments traversed commonly accepted ideas. Helmholtz ascribes difference of "timbre" to the difference in the number of harmonics accompanying a given note sounded on different instruments. According to this, it should be possible to produce the "timbre" of any instrument by sounding the note together with the requisite number of harmonics; but such was not the case. He also denies that it can be influenced by "phase;" whereas a mere inspection of the wave diagrams yielded by the same two notes differing variously in phase proved the impossibility of such an assumption. In the light of König's theory it was possible to imitate synthetically the "timbre" of some of the coarser musical instruments, a practical proof of its correctness.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

2nd June, 1890.

8487. Townsend, Andrews, & Townsend ..... Signals for railways.
8490. Sutcliffe, W. ..... Looms.
8491. Charlton & Pepper..... Reducing valves.
8494. Fenby & Pollock ..... Hydraulic valves.
8496. Smith, J. ..... Spinning machines.
8499. Schulze-Berge & Schulze-Berge..... Air pumps.
8504. Butterfield & Renton Apparatus for finishing paper.
8505. Phenix, J. ..... Fuel economisers.
8510. Broadhead, Beesley, & Evans ..... Boiler furnaces.
8511. Burlinson, J..... Boiler gauges.
8517. Dilitz & Kretschmann Railway couplings.
8520. Favier, P. A. ..... Machines for decorticating.
8523. Paddon, E. F. ..... Furnaces.
8525. Allen, S. L. . ..... Cultivators. (7th November, 1889.)
8527. Lake, H. H..... Air compressors (*Muller*).
8528. Mills, B. J. B. ..... Transmitting power (*Johnson*).
8529. Simons, P. ..... Rack railways.
8531-2. Neate, P. J..... Edge runner grinding mills.
8538. Mick, Kursteiner, & Janenz..... ..... Embroidering machines.

3rd June, 1890.

8539. Allison, H. J..... Skelp welding machine (*Spiral Weld Tube Company*).
8544. Johnson & Hutchinson Filter presses.
8548. Kent, E. A..... Machine for making paper tubes.
8550. Dorman, W. H. ..... Boot machinery.
8552. Low, J. B. ..... Railway cars.
8554. Eitle, C. ..... Apparatus for charging retorts.
8556. Paul, R. W. ..... Tool-holder.
8561. Foote, C. H. ..... Hot-blast stoves.
8563. White & Boyd ..... Brick-making machines.
8564. Taft, J. C. ..... Twist drills.
8569. Harmon, C. S. ..... Lathes.
8570. O'Brien & Carew..... Anvils.
8579. Johnson, J. Y. ..... Paper-winding apparatus (*Bingham*).
8580. Molison, T..... Potato-dressing machine.
8581. Wise, J. N. ..... Expansion gear for rolls.
8583. Day, W. H. ..... Candle-moulding machines.
8591. Clark, J. A. ..... High-pressure valves.
8593. Holmstrom, C. ..... Breechloading guns.
8594. Haubert, S. C. ..... Toothed wheels.
8597. Stuart, S. ..... Construction of ships.
8598. Wenger, A. ..... Railway brakes.
8602. Carl, R. A. ..... Riveting machines.
8607. Sherman & Bates..... Car axles.
8608. Jenson, C. A. ..... Corrugating tubes (*Kossuth*).
8610. Farebrother, Papineau, & Pether ..... Mechanical fire cleanser.

4th June, 1890.

8613. Porges, P. ..... Hydraulic power transmitter.
8614. Wise, W. L. ..... Manufacture of filtering plates (*Eyen & Bassenge*).
8615. Perkins, J. E. S. ..... Rollers.
8616. Moyé, H. ..... Railway couplings.
8622. Goodwin, Barsby, & Pochin..... Stone-breaking machines.
8627. Cooper & Ormerod ..... Looms.
8628. Holmes, J. ..... An improved machine.
8632. Commons, S. ..... Packing for steam engines.
8636. Rylands & Emmet ..... Air-pressure pistons.
8639. Blackmore, Clark, & Standfield ..... Floating docks, &c.
8640. Sperryn, J. N. ..... Tube couplings.
8643. Hern, S. ..... Obtaining motive power.
8644. Dewar, R. M. ..... Circulation of water in boilers.
8645. Lea & Brett ..... Gas engines.
8649. Paxman, J. N..... Multitubular steam generators. (13th November, 1889.)
8660. Boult, A. J. ..... Steam generators and cannon (*Reynolds*).
8669. Weiss, R..... ..... Embroidery machines.
8670. Branch, E. L..... Shifting eccentrics.
8672. Daudeteau, L. M. R. ... Firearms.

5th June, 1890.

8676. Barford & Perkins..... Crushing mills.
8679. Grahame, J. ..... Removing smoke from tunnels.
8680. Parini, G. C. ..... Blast fans.
8684. Cutting, H. ..... Compound engines.
8686. Caddick, D..... Heating furnaces.
8687. Crawshaw & Battye ... Signalling on railways.
8688. Keith, J. ..... Furnace grates (*Bartlett Hayward & Co.*).
8690. Nelson & Shaw..... Mule.
8691. Harris, H. B..... Percussion fuse.
8692. Thompson, W. ..... Tentering machines.
8693. Whitlaw, Jun., & Kincaid ..... Looms.
8696. Bickle, T. E ..... Pulverisers and amalgamators.
8697. Annett, J. P. ..... Compensator for signal wires.
8701. Agudio, T. ..... Boiler tubes.
8706. Beesley, F..... Drop-down small arms.
8707. Von Langer & Cooper... Gas furnaces.
8713. Wetherell, A. ..... Car couplings.
8714. Haddon, H. J. ..... Journal bearings (*Andrews & Andrews*).
8715. Attenborough & Mottershaw ..... Knitting machines.
8721. Chesebrough, R. A..... Protection of ships against fouling, &c.
8727. Justice, P. M..... Poppets for boring bars (*Taylor*).

6th June, 1890.

8744. Richardson, E. ..... Screw-cutting.
8748. Jorling, E. ..... Manhole doors.
8755. Craig, J. ..... Motive power from tides.
8759. Von Langer, J. ..... Iron and steel.
8762. Boult, A. J. ..... Computing machines (*Sharpe*).
8772. Northrop, W. B. ..... Typewriting machines.
8781. Bousfield, E. T. ..... Typewriters.
8783. Gardner, C. F. ..... Sewing machines (*Stanley Manufacturing Company*).
8784. Müller, J. A..... Liquid meters.
8785 Liardet, L. E. ..... Chain shackles.
8788. Johnson, J. Y. ..... Purifying feed water (*Chapsal*).

7th June, 1890.

8790. Watson & Robertson ... Evaporating and distilling.
8793. Chidlaw, R. ..... Wheel cutting machines.
8794. Blackadder, A. C. ..... Steering gear.
8795. Norman, G..... Pulleys and drums.
8797. Maleham, C. H..... Drop-down guns.
8807. Harris, P. T.... . ..... Metallic packing.
8808. Leslie, R. ..... Furnaces.
8810. Reffitt, J. ..... Machinery for pressing woollen fabrics.
8813. Turney, F N. ..... Machine for splitting skins.
8815. Carroll, J. ..... Combing machines.
8816. Harris, H. M. ..... Aërial navigation.
8824. Richardson, R. ..... Steam engines.
8831. Gardner, J. ..... Typewriting machines.
8835. Marshall, J. G. ..... Bearings.
8841. Mennons, F. L. F. H. ... Tubular boilers.
8842. Kleczénski, W..... Lever pump.
8844. Huelser, C. ..... Sewing machines (*Kuhut & Deissler*).
8846-7. Archambault, A. ..... Looms.
8848. Pocock & Pocock ..... Brakes for vehicles.
8851. Poupard, W. J, Jun. ... Weighing machines.
8859. Bayly, J. P. ..... Water wheel (*Le Duc & Bertrand*).
8860. Bayly, J. P. ..... Steam actuated valve (*Patten, Robertson, & Fraser*).

ELECTRICITY.

2nd June, 1890.

8495. Williams, P. H..... Magneto-electric brakes.
8534. De Benardos & Lloyd & Lloyd ..... Accumulators.

3rd June, 1890.

8559. Rixom, W. ..... Connecting electric wires.
8567. Cobb, H. B. ..... Conductors and conduits.
8578. Johnson, J. Y. ..... Accumulators (*Hering*).
8595. Granville, W. P..... Electric logs.
8599. Anderson, F. ..... Generation of currents.

4th June, 1890.

8651. Smith, T..... Casing for conductors.
8652. Greene, E. M. ..... Magneto-telephone systems.

5th June, 1890.

8703. Thompson, W. P. ..... Electric welding (*Coffin*).
8720. Walter, H. E. ..... Electromagnetic brake.
8730. Miner, W. M..... Electric soldering irons.

6th June, 1890.

8749. Héndlé & Poole ..... Arc lamps.
8754. Garrett & Lucas..... Protecting conductors from lightning.
8758. Colacchi & Rolland ... Electric generators.
8777. Lake, H. H..... Electric call-bells (*Hathaway*).
8778. Groswith, H..... Electric motors.
8787. Schanschieff, A. ..... Motors and dynamos.

7th June, 1890.

8800. Thompson, W. P. ..... Accumulators (*Pearl*).
8819. Selwyn, J. H..... Compasses.
8853. Piat, A. ..... Electric motors.
8854. Desruelles & Chauvin Measuring electrical energy.

CHEMISTRY.

2nd June, 1890.

8498. Macfarlane & Macfarlane ..... Treatment of sewage.
8506. Imray, O..... Colouring matter (*Farbwerke vormals Meister, Lucius & Brüning*).
8530. Willcox, B. ..... Azo colours (*Farbenfabriken vormals Friedrich Bayer & Co.*).
8535. Pitt, S. ..... Illuminating gas (*Jerzmanowski*).

3rd June, 1890.

8541. Hart, J. J. ..... Colouring matters.
8572. Thomas & Hillman ..... Galvanising ironwork.
8609. Fyfe, W. W. ..... Amalgamating ores.

4th June, 1890.

8655. Miller, E. C..... Anti-friction alloys (*Magnolia Anti-Friction Metal Company*).

5th June, 1890.

8716. Edwards, E. ..... Zinc (*Lange*).
8717. Blinkhorn, E. ..... Explosives.
8725. Willcox, B. ..... Alizarine (*Farbenfabriken vormals Friedrich Bayer & Co.*).
8726. Johnson, J. Y. ..... Artificial indigo (*Badische Anilin & Soda Fabrik*).
8728. Fenner & Colls ..... Naphthalene.

6th June, 1890.

8733. Bruce, W. ..... Carbonic acid gas.
8752. Cryer, W. ..... Oxygen.
8786. Léon, G. ..... Sulphuric acid.

7th June, 1890.

8799. North, A. ..... Dyeing cotton.
8811. Kolf, H. ..... Gunpowder.
8820. Clark & Clark..... Alloys of allumiuium.
8826. Coombs, J. ..... Gold extraction.
8836. Blinkhorn, E. ..... Nitrate of ammonia.
8843. Müller, E. ..... Nitrifying cotton.

MISCELLANEOUS.

2nd June, 1890.

8488. Andrews, J. ..... Screws and screw nails.
8519. Prinz, O. ..... Cement.

3rd June, 1890.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

CORK MAKING MACHINE.—*G. Duncan & J. Latta, Liverpool.*—The process consists essentially in cutting the rough pieces of cork into strips, in shaping the strips into cylindrical rods, in smoothing or polishing the cylindrical rods, and finally in cutting the smoothed or polished rods into lengths so that each length forms a cork. The cork is cut into strips preferably square in cross-section by means of knives in any usual or suitable manner, or a circular saw may be used. The strips are made cylindrical by being passed endwise between cutters rotating round a centre.

FIG. 1

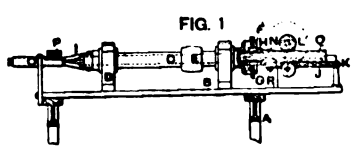

FIG. 3

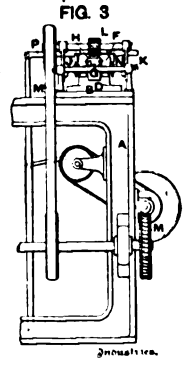

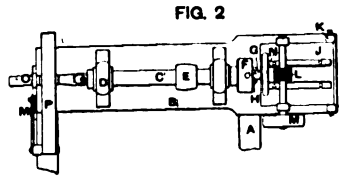

FIG. 2

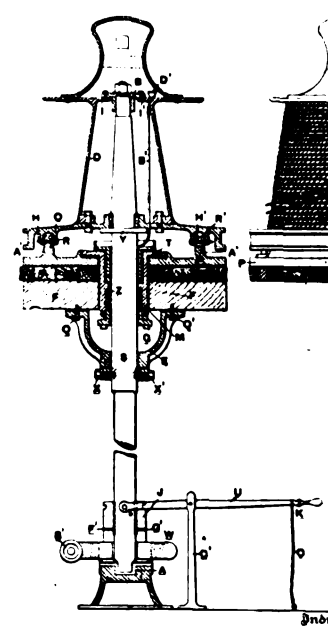
The strips are then smoothed or polished by contact with a rotating drum, moving band, or reciprocating bar coated with glass or some other abrading substance, the smooth cylindrical strips being finally cut into corks of the required length by means of knives or blades in any convenient way. In the accompanying illustrations a machine is shown for performing these operations, excepting the first and last, which is preferably done in the usual manner. On the front end of a hollow mandrel C are fixed a cylindrical cutter G and radial cutter H. To the opposite end of the mandrel are secured clamps I. The corks are formed as follows:—The mandrel C is revolved at a very high speed by a belt passing round the pulley E, and revolves the cutters G and H with it. Strips of cork are then passed to the knives between eed rollers L in a direction corresponding to the axis of the mandrel. The cutters, revolving at a high speed, cut the corners off the strips and form them into cylinders. These cylindrical pieces then pass through the tubular mandrel and out at the opposite end, where they are gripped by the clamps I and revolved. Above the cork, as it leaves the mandrel, is placed a flat bar P with its under side covered with an abrading material such as glass. This bar receives a reciprocating motion from an upright bar oscillated by a pin in a revolving wheel, shown in Fig. 3. The bar P rests upon the cylindrical cork as it leaves the mandrel, and by its reciprocating motion and the rotation of the cork smoothes the latter down as it is gradually passed from the machine through the steadying tube O. Claims: (1) Cutting cork into strips shaping the strips so as to form cylindrical rods, smoothing or polishing the rods, and cutting the said rods into lengths as described; (2) in apparatus for making corks the combination of rotating cutters with an adjustable feed table; (3) in apparatus for making corks the combination of rotating cutters with feed rollers and a steadying strap N; (4) in apparatus for making corks the combination of cutting and smoothing or polishing apparatus for the purpose set forth.—No. 10651. July 2nd, 1889. 6*d*.

CAPSTANS.—*J. Cowley, Great Yarmouth, & F. & J. Lelen, London.*—Hitherto great difficulty has been experienced in the use of wire ropes on capstans, but by the improved construction of capstan here described the inventors claim to overcome these difficulties, and, besides, to enable it to be worked single handed. Fig. 1 is a sectional elevation and Fig. 2 a front elevation of this improved capstan. It is revolved by a vertical shaft S, whose upper part is secured to the barrel, and its lower supported in a step bearing A. The shaft is also supported in a bearing T fixed to the deck, and it is prevented from rising out

FIG. 1.



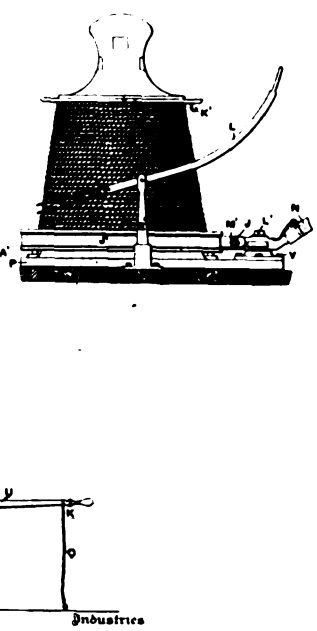


FIG. 2.

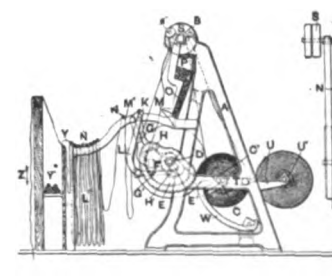
of its step by the collar E fixed to the under part of the deck. On the base plate P is a circular bearing path A^1 for the rollers R, mounted in the lower flange of the capstan barrel. A friction band J^1 passes around the channelled part of the lower flange, and constitutes, with the swivel lever N, a brake for retarding the motion of the capstan when paying out. When winding in, the capstan is revolved by steam or other power transmitted through the worm S^1 and worm-wheel W to the shaft S. The worm-wheel W is loose upon the shaft S, but may be secured to it by the clutch J, operated by the lever O. Claims: (1) The improved capstan, arranged, constructed, and operating as and for the purpose described; (2) in steam and other capstans the use of wire ropes for operating the same as set forth.—No. 8749. May 27th, 1889. 8*d*.

FINISHING TEXTILE FABRICS.—*R. Clegg, Manchester.*—A continuous or endless running of textile fabrics through calenders, during the finishing processes, is attained with this machine, by causing an accumulation of cloth to be held in suspension, and in advance, so to speak, of the calender. Such accumulation affords the attendants sufficient time to attach the last end of the cloth, so held in reserve, to the first end of another piece of cloth to be operated upon. By this arrangement there is no empty running of the calender. In the accompanying illustrations B B^1 are the draw rollers. Below these in the brackets C is the box C^1 with the cloth upon it. The cloth, as it is drawn off the box C^1 by the rollers B B^1, fall from the latter over rods N which are moved forward at regular intervals, and so take up only a certain quantity of cloth. These rods are stored up in a hopper P, and are taken from there singly and moved forward to the point M^1 by levers L, G, and K, worked by the cams E. The cams are suitably formed to give the levers L, G, and K the motion necessary to perform this action. As the succeeding rod is moved to the point M^1, the proceeding one is dislodged and rolls down the incline brackets, with its lap of cloth, to the point Y. When the cloth has been taken off a rod by the calender, the pull of the cloth forces the rod over the point Y, so that it drops into the collecting box Y^1. A further part of the invention is an arrangement for releasing the shaft or rod carrying the batch or box of cloth from the brackets which support it. It consists of two brackets C C, one at each side of the frame, each having bearings somewhat like three sides of a square, one of the three sides of each forming part of the lever T, and can be lifted up so as to leave one side of each bearing clear or open. These levers T have at each end an incline U. When it is desired to remove the empty box and replace it by a full one, the full one is pushed forward from the point U^1 and the pivots of the shaft carrying the full box coming against the two inclines U on the levers T, lift the ends forming one of the three sides of each bearing, which hitherto secured the pivots of the box when being operated upon. The full box is thus forced forward against the empty one and throws it out of the bearing now open. Under each bracket C C are curved arms W in position to receive the dropping box and deposit it in a position for the attendant to pick up conveniently. Claims: (1) A machine or apparatus by means of which continuous or endless running of textile fabrics through calenders during finishing processes, &c., is attained, having folds L^1 of cloth or fabric hanging on rods arranged substantially in the

FIG. 1.



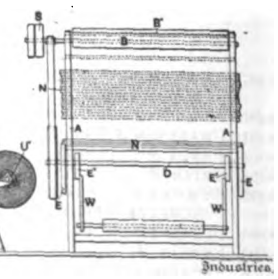


FIG. 2.

same manner described; (2) the arrangement for carrying the rods from one point to another, which arrangement consists in the cams E E^1, levers G G^1, swivel levers K, rods L, passage O, chamber P, all arranged and employed in conjunction with each other for the purpose and substantially in the manner described; (3) the arrangement for releasing the shaft or rod carrying the exhausted box or batch from the bearings, which arrangement consists of the brackets C, levers T, inclines U, curved arms W, all arranged and employed in conjunction with each other for the purpose described.—No. 7386. May 3rd, 1889. 8*d*.

SMOKE CONSUMER.—*R. & D. Walker, Middleton, Lancashire.*—The escaping smoke products of combustion and vapours are treated with steam so as to saturate the carbon and other suspended matters, and by so increasing their specific gravities cause them to become precipitated in a suitable chamber. The accompanying illustrations show a sectional elevation and plan of the apparatus used in this process, adapted to an ordinary horizontal boiler. The boiler A^1 is set in the ordinary brickwork B^1, and has an under return flue C and side flues D as is usual. The side flues meet at the back of the boiler at the dampers E P, the smoke passing through the damper E to the exhaust fan F or other suitable exhausting or forcing apparatus. The other damper P closes the entrance to the flue G which leads to the chimney H. Thus by closing one damper or the other the whole of the smoke could be directed either to the condensing apparatus or to the chimney. In the illustrations the whole of the smoke is passed on to the condensing apparatus as indicated by the arrows. The fan F, which may be driven by any suitable means, draws the smoke from the boiler flues and forces it into the pipe I, which extends from the fan into the condensing chamber J. This chamber may be built of brick as shown. The smoke pipe I, which extends the length of the bottom of the chamber, is turned upwards and backwards as shown in Fig. 1 so as to project the smoke into the chamber. At the other end of the chamber, and about opposite to the emission mouth of the smoke pipe, is placed a steam pipe K, through which is blown steam from the boiler or from the engine exhaust or other source into the chamber. This inflowing supply of steam meets the smoke as it issues from the smoke pipe I, and the two currents become thoroughly commingled. The condenser is thus filled with moist vapour and smoke, the result being that the particles of carbon in the smoke or heated products of combustion become saturated with moisture and fall to the bottom of the chamber, from whence the accumulated deposit may from time to time be

FIG. 1

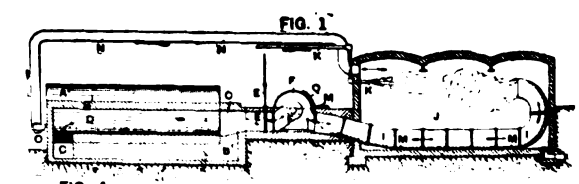

FIG. 4

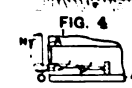

FIG. 3

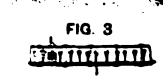

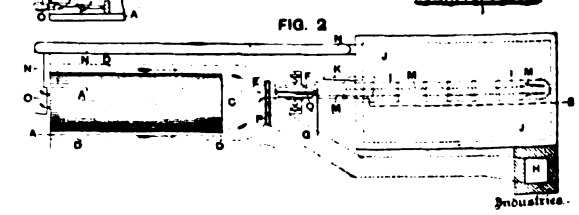

FIG. 2

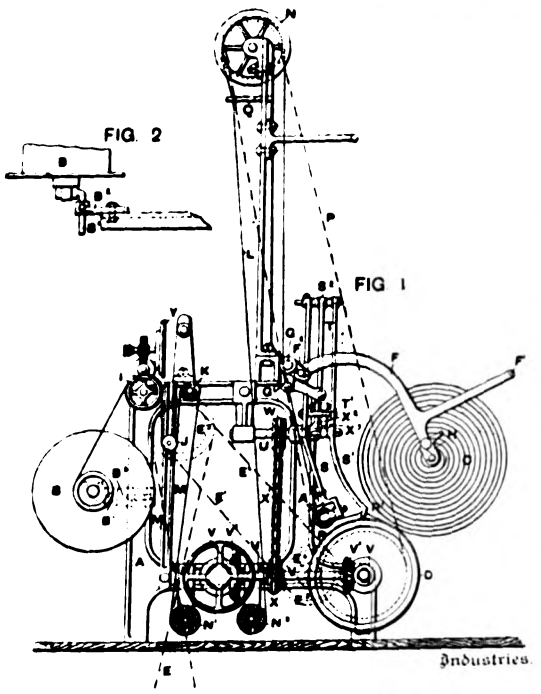
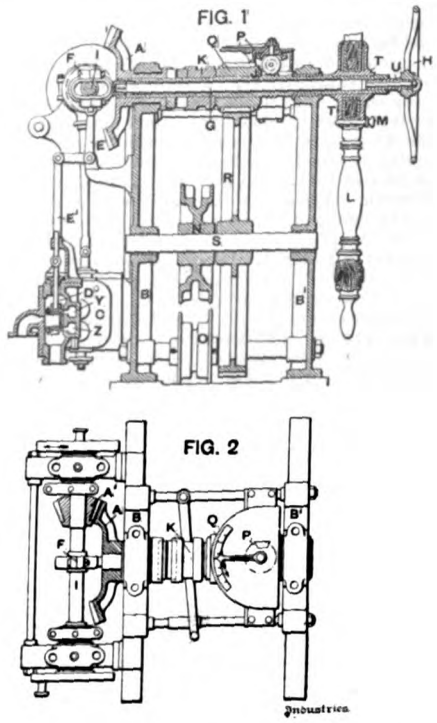


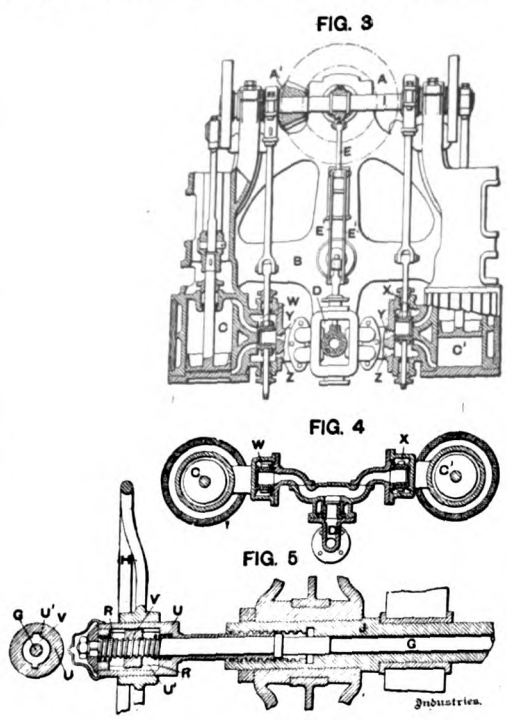
removed. The bottom of the condensing chamber is made of perforated metal or tiles, or it may be formed with intersecting runlets leading to the sides or ends, so as to allow the moisture to drain away from the precipitated matters, as, for example, through the drain pipe shown in Fig. 1. To assist in saturating the smoke with moisture, spray pipes M may be placed in the smoke pipe I as shown in Fig. 3. Water under pressure is led into these pipes, and the pipes are perforated at intervals so as to throw finely-divided sprays of water into the interior of the pipes. A similar spray might be directed into the fan and assist in keeping it cool. Claims: (1) The general arrangement and combination of apparatus for condensing and consuming smoke and vapours as described and shown; (2) in apparatus for condensing smoke and vapours, a closed condensing chamber into which the smoke is led or forced and there saturated or humidified by means of steam so as to cause precipitation of the particles of carbon as described and shown; (3) in apparatus for condensing

Digitized by Google

smoke and vapours, the condensing chamber J in combination with the fan F, smoke pipe I, and steam jet K, for the purposes described; (4) in apparatus of the indicated type, returning the uncondensed smoke from the condensing chamber to the furnace and forcing it thereinto as described; (5) in apparatus of the indicated nature, humidifying the smoke or heated products of combustion on their way to the condensing chamber by the introducing of sprays of water or steam into the fan and smoke pipe as described.—No. 8478. May 22nd, 1889. 8*d*.



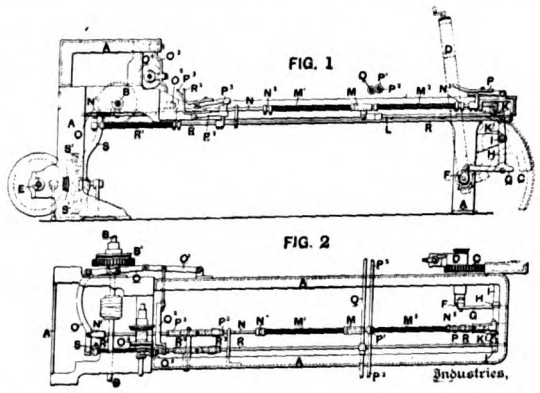
WARP BALLING MACHINES.—*J., J. P., & J. Sunderland, Nelson, Lancashire.*—Improvements are here introduced into the above machine for making long chains, in ball form, in a more expeditious and efficient manner than is effected by balling machines of the present kinds. Fig. 1 is a sectional elevation of a balling machine constructed in accordance with our invention; Fig. 2 is a view of detached parts of the mechanism. The warp threads are unrolled from the back beam B and wound up in ball form C by the revolving movement of the drum D, which is driven by the straps E E^1 and suitable toothed gear wheels. A steady action and even pressure is ensured whilst balling by two angular side pieces F pressing on the ball spindle. The side pieces F are bolted together, and are connected to the ball spindle by hooks H, which are so arranged as to facilitate the removal of the ball from the pieces F. The back beam B is placed as shown, with its arbours resting in notches formed in slide pieces B^1, capable of moving horizontally in slots formed in fixtures B^2, for lateral adjustment to the various widths of back beams that may be used. The warp to be balled from the back beam B is conveyed in a sheet-like manner over the roller I and K, and supports the falling roller J, which performs the same functions as the falling roller of a beaming frame, moving up and down in slots in the vertical standards M. When leaving the roller K the warp is conveyed downwards, and made to partially lap the drum V through the medium of guide rollers N^1 and N^2. The warp L is from thence conveyed



upwards from the roller N^2 over elevated roller N, the distance between the two being sufficient to allow the warp to gradually contract from its sheet-like form in passing to and through the eye of the bracket Q to the elevated roller N. From this roller the warp, now in chain form, is conveyed under pulley R and through the eye R^1, of the lap-traversing device, which guides the chain from one side to the other, forming a lap backwards and forwards over the surface of the revolving ball of warp. The lap-traversing device is composed of two arms S and S^1 on the upright T; both arms are fixed together rigidly by the bolt T^1, and are made to swing backwards and forwards similarly to the pendulum of a clock. The elevated roller N and drum V are driven from the drum D, the former by the counter-strap P, the latter by the bevel gear wheels and shaft V^1. A revolving crank X^2 imparts motion to the traversing device, the crank X^2 being revolved by the shaft V^1 through the sprocket wheels W and chain X^1. Claim: In a warp balling machine the arrangement and combination of the parts described and illustrated.—No. 9889. June 17th, 1889. 8*d*.

LUBRICATORS.—*J. Rebmann, Horgen, Switzerland.*—This new lubricator is for working with grease. The grease is subjected to the combined pressure of a spring and screw. The reservoir is of cylindrical form placed vertically, and is fitted with a piston that is pressed downwards by a coiled spring surrounding its rod. The piston rod passes up through the top cover, and has attached to its end a small button for moving the piston. The top cover is made in one with the reservoir, but the lower cover is made to screw into the cylinder, and it is formed with the necessary stem for fixing the lubricator. To fill the reservoir it is removed from its bottom cover and the spring-loaded piston drawn back to the end of the cylinder. Grease is now placed into the reservoir, and the reservoir rescrewed upon its bottom cover until the pressure exerted by the spring upon the piston is sufficient to keep the supply of grease well down to the outlet in the stem. When a part of the grease has been used the reservoir is screwed still farther down on to its lower cover, so bringing the pressure of the spring up to its original force. Claim: A self-acting lubricator for greases regulated by the combination of a screw and spiral spring in such a way that the spring acting upon a piston is reinforced by screwing the box over the bottom as and for the purpose described.—No. 16929. October 26th, 1889. 6*d*.

STEERING GEAR.—*W. P. Thompson, Liverpool. (P. & V. Callard, Harre, France.)*—This system of steering is based upon the following: (1) The use of bevel gearing as transmitter between the motor shaft and the intermediate shaft which gears with the shaft carrying the steering chain drum; (2) the arrangement of the motive cylinders vertically at the back of the machine; (3) the method of fixing the intermediate shaft permiting its use as gearing when the steering is done by steam, as the working shaft when the steering is done by hand, and forming a guide for the spindle that works the admission valves of



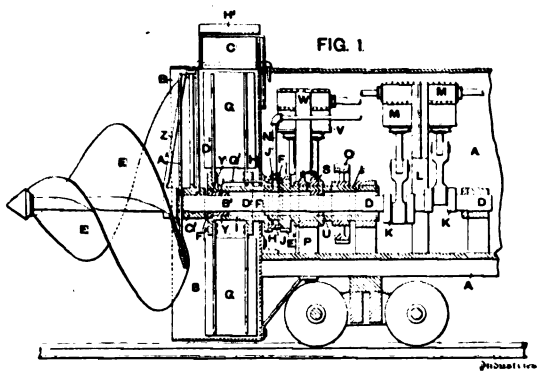
the engines. In the illustrations, Fig. 1 is a vertical longitudinal section, Fig. 2 a plan, Fig. 3 a transverse section, and Figs. 4 and 5 sectional details of the machine. The cylinders of the engines C are fixed at the back of the machine, and their pistons are connected as usual to the motor shaft I. The slide valves of these engines are of the type described by the inventors in a previous patent, No. 1831 of 1889. Steam is admitted to the engines through the reversing valve D, which is coupled to an elbow lever E pivoted to the framing. The upper arm of this lever is connected to the rod G, so that by a longitudinal sliding motion of the latter the valve D is shifted. The rod G passes through the hollow intermediate shaft J. This intermediate shaft is geared by the beveled wheels A A^1 to the motor shaft, and by the pinion Q and large wheel R to the shaft carrying the usual steering chain wheel N. When the steering is to be performed by steam the hand-wheel L is disconnected from the intermediate shaft J by withdrawing the pin M. The valve D is then worked by the small hand-wheel H in the following manner. The wheel H is mounted upon a metal sleeve U, threaded upon its outer surface to screw into the hollow intermediate shaft J. Through the sleeve U is passed and secured the reduced end of the

sliding rod G, which by reason of its connection to the motor shaft is prevented from turning upon its axis. Thus by turning the wheel H the shaft G is forced forwards or backwards, and the motion being transmitted through the lever E the valve D is opened in one or other direction and the engine worked accordingly. By the motion, however, of the intermediate shaft, the rod G is screwed back to its normal position and the valve D closed. To prevent the excessive displacement of the rudder by turning the wheel H too much, an arrangement is made as illustrated in Fig. 5. The sleeve U is made of a box form, and the end of the rod G is threaded. Upon the threaded part of G is a nut V, which partakes of the rotary motion of the wheel H, and has besides freedom longitudinally. As the rod G cannot revolve, it will be seen that the motion of the sleeve U in the intermediate shaft J is limited both ways. When hand steering the motor is disconnected from the intermediate shaft J by a clutch K. Five claims are made.—No. 9730. June 13th, 1889. 8*d*.

LOOMS.—*J. Greenwood & J. Ashworth, Bury, Lancashire.*—The treading apparatus for operating the healds in looms is here referred to. In plain looms the healds are attached by cords to horizontal levers working upon a stud, such levers being actuated by eccentrics or tappets for the purpose of opening and closing the shed. The present method and form of the tappets has been found to be unsatisfactory, because at certain parts of each revolution of the tappet it temporarily left the horizontal levers, leaving them free and under no control, so causing damage to the healds. To prevent this the tappets are made, according to the invention, of such a size and shape that they never leave the bowls of the levers. The tappets are approximately circular pieces placed eccentrically upon their shafts, but having the part furthest from the centre or true arc struck from the centre of the shaft. Thus when the levers are right up or down they remain in that position for a short dwell to give the shuttle sufficient time to cross the loom. Claim: The formation of tappets so shaped and adjusted with regard to each other that their surfaces at no time leave the treading bowls.—No. 11,380. July 16th, 1889. 6*d*.

SPINNING AND DOUBLING COTTON.—*R. Curtis & J. Wain, Manchester.*—An improved method is described in this specification for putting into and out of gear the drawing-out catch-box, the front roller catch-box, and the drawing-up friction gear in mules and twiners, the cam shaft and its appurtenances being dispensed with. Fig. 1 is an elevation partly in section, and Fig. 2 a plan view of so much of the headstock of a self-acting mule as is necessary to illustrate the invention. A is part of the headstock framing, B the back-shaft, C the quadrant, D the quadrant arm, and E the scroll shaft. For the purposes of the invention there is mounted on the quadrant axle, at its inner end, a short arm F which is connected by a link G to a hanging lever H fixed to or cast on a transverse rocking shaft I carried in suitable bearings at the front of the headstock. On this transverse shaft is also fixed or cast an upright lever K, and the upper end of this is connected by a link L to a sliding boss M working between two coiled springs M^1 and M^2. The boss M is on a sliding rod N, whose back end is connected at N^1 with the cranked change lever O, which

actuates the back-shaft catch-box B^1 for putting in gear the drawing out motion of the carriage. This lever O also acts upon another lever O^1 which is connected to the front roller catch-box O^4, thus throwing the drawing-out motion and the front roller catch-box into and out of gear simultaneously at the proper moment. As the spindle carriage is going out and the quadrant C and the quadrant arm D move in the same direction, the short arm F acting on the sliding boss M compresses the spring M^1, the rod N being prevented from sliding with the boss M by means of a catch lever P at the front end, and the other spring M^2 remaining perfectly free and idle. As the carriage completes its stretch, a boss P^1 on the counter faller shaft P^2 raises the catch lever P by coming into contact with its inclined part, and allows the spring M^1 to expand. The rod N is thus moved in the direction of the arrow, and puts the drawing-out and front roller catch-boxes out of gear, and at the same time lets down the catch lever P^3, at the back end of the headstock. As the carriage runs in towards the rollers the reverse movement of the quadrant draws the sliding boss M in the opposite direction, thus compressing the spring M^2, which is held and released in a similar manner to the spring M^1 by the catch lever P^3, and so throws the drawing-out and front-roller catch-boxes into gear again. A similar contrivance, but acting in one direction only, is used for actuating the scroll friction gear for drawing in the carriage. In this case the rod N is provided with one spring, which is compressed by a second lever K^1 upon the lever I. Claim: The arrangement of apparatus substantially as described and illustrated for putting into and out of gear the drawing-out and front roller catch-boxes, and the drawing-up friction gear, whether employed separately or in combination with each other.—No. 10781. July 4th, 1889.



RAILWAY WHEELS.—*J. Clemenson, London.*—This invention relates to an improved method of constructing railway, tramway, or other wheels, whereby great lateral stability, combined with elasticity and direct resistance to torsional strains, are obtained. According to one method of constructing these wheels, the nave is made of any suitable material and formed with spokes or radial arms, and also with a groove on each of its sides or faces. The tire is rolled with a ridge upon its inside, and has a groove cut in each side of the ridge; recesses are also formed in the ridge for the reception of the spokes. When the wheel is built up, the nave is within the tire, the ends of the spokes or arms fitting into the recesses formed in the ridge of the tire. Segmental plates are then placed upon each side of the wheel and bolted together with the spokes of the wheel between them. The edges of these plates are formed to fit the grooves cut in the faces of the nave and in the ridge of the tire. They are also made with depressions to stiffen the wheel when the plates are bolted in place.

Digitized by Google

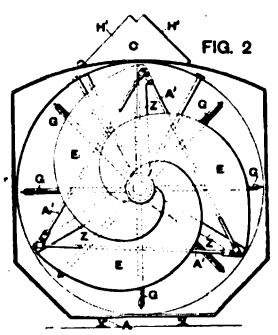
Claims: (1) In a wheel the combination of the nave and spokes with the discs and tire as described; (2) the general arrangement of parts and method of construction as described.—No. 9936. June 18th, 1889. 6*d*.

ROTARY SNOW PLOUGHS.—*W. P. Thompson, Liverpool. (E. P. Caldwell, Minneapolis, U.S.A.)*—This machine is intended for clearing snow from railway tracks. It consists essentially of a revolving spiral cutter head which feeds the snow to a shallow cylindrical chamber. The cylindrical chamber is fitted with vanes which revolve and throw the snow outside the track. In the illustrations of this snow plough, Fig. 1 is a longitudinal

FIG. 1.

vertical section, Fig. 2 a front elevation, and Fig. 3 a rear elevation. The whole of the machinery is mounted upon a suitable car truck and it is worked by its own special engines. E is the spiral-bladed cutter mounted upon the front end of a stiff horizontal shaft D, and revolved by an engine M. This spiral-bladed cutter is mounted immediately in front of the cylindrical fan casing B in which are revolved the vanes or blades G. The blades G are secured to a second hollow shaft I which surrounds that of the spiral cutter. In the top of the chamber B are openings C for the discharge of the snow by the revolving fan. One of these outlets is opened at a time according to the side upon which the snow is to be discharged. The fan is driven by two engines V placed upon each side of the shaft I and having their separate crank-shafts R geared to the hollow shaft I by toothed wheels O. The two shafts are thus driven independently of each other, and therefore the motion of the fan may be reversed without effecting the motion of the spiral cutter. In the hollow shaft I is cut a groove F which is closed by a sliding ring J, so forming a small annular chamber. The ring J is held stationary

FIG. 2



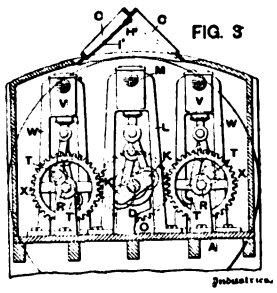


FIG. 3

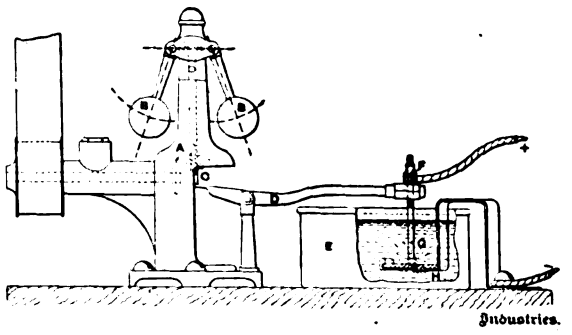
whilst the shaft I revolves, and thus forms the means of communicating the annular chamber with the steam supply through the pipe N. The annular chamber communicates further with small grooves surrounding the bearing Y, and so these grooves are kept supplied with steam, which prevents the lubricating matters from becoming frozen. The other bearings of the machine may be treated in like manner. Nine claims are made.—No. 8670. May 24th, 1889. 8*d*.

EVAPORATING LIQUIDS.—*R. C. & C. H. Garton & W. Lawrence, London.*—The improved apparatus comprises a tube or series of vertical tubes heated from the inside by the passage of steam, and having the liquid to be evaporated passed over their outer surfaces, the chief point of the invention being the shape of the tubes. These are fluted, grooved, or channelled, either spirally, longitudinally, or laterally, to cause the liquid to spread more uniformly over the evaporating surfaces. Claims: (1) In apparatus for evaporating, heating or cooling, liquids, and not working under pressure or *in vacuo*, an arrangement comprising one or more, or a set of vertical or nearly vertical tubes, which are fluted, grooved, or channelled, either spirally, longitudinally, or laterally, or are spirally twisted, and means whereby the liquid to be treated is caused to flow in a film down the exterior of such tube or tubes, while the steam or other acting medium is brought into contact with the interior of the tube or tubes; (2) in apparatus for evaporating, heating, or cooling liquids, and not working under pressure or *in vacuo*, an arrangement comprising one or more or a set of vertical or nearly vertical tubes which are fluted, grooved, or channelled, either spirally, longitudinally, or laterally, or are spirally twisted, and means whereby the liquid to be treated is caused to flow in a film down the inside of such tubes, while the steam or other acting medium is brought into contact with the interior of the tube or tubes. No. 11350. July 15th, 1890. 8*d*.



ELECTRICITY.

CONTROLLING THEATRE DOORS, &C.—*H. J. Harris, London.*—The doors employed in connection with the invention are sliding doors, sliding back into the thickness of the wall or into a suitable casing. Rollers are fixed to the top and bottom of the doors to ensure the door sliding freely. A vertical sliding bolt with a bevelled upper end is fitted in the floor and pressed upwards by a spring, so that when the doors are pulled out and closed the bolt is pressed upwards, and, engaging with the door, locks it. A rubber spring is attached to the inner edge of each door and to the back part of its case to pull the doors open when the bolt is withdrawn. Attached to the lower end of each bolt is a soft iron armature, and an electromagnet is placed in such a position as to act upon the armature and withdraw the bolt when the magnet is vitalised. In a theatre or other public place the electromagnets of the various doors fitted with this appliance are all placed in circuit and switches provided in different parts of the building for closing the circuit and withdrawing the bolts in cases of fire or panic. The doors can be opened independently by a lever or other device attached to the sliding bolt and operated by hand. Claims: (1) The combination of a sliding bolt operated by an electromagnet to lock and release the doors as described; (2) the combination with an ordinary hinged door of a bolt operated by electromagnet; (3) the combination of a series of doors constructed as set forth in claims 1 and 2 arranged to be opened simultaneously by an electric current as set forth; (4) the combination with a vertical bolt of a rod or other suitable device for opening the door without employing the electric current; (5) an arrangement for opening a door by means of an electric current constructed as described.—No. 10285. June 24th, 1889. 8*d*.

CONDUIT FITTINGS FOR ELECTRIC CONDUCTORS.—*R. E. B. Crompton, Chelmsford.*—To facilitate the introduction and withdrawal of the copper strips from the conduits, the inventor makes use of movable insulator carriages. These consist of a frame made of suitable material supported on three or more rollers or wheels. On these frames are mounted any required number of pairs of vertical insulators, which carry grooved wheels or small pulleys with flanges to support the conductors. These insulator carriages are made so that they can be readily drawn into and along the conduit. It will be seen that by the employment of these carriages the openings in the conduits may be made a great distance apart, and after the copper conductors have been drawn in, a number of these carriages can be drawn in afterwards at certain intervals apart to support the conductors at a proper height and position. For the purpose of making the conductors taut, there is built into the wall of the conduit, at a position near the surface box, one or more pairs of bars crossing the conduit. These cross-bars are built in pairs one above the other at a sufficient distance apart to admit the conductors to pass between them. Resting with one leg on each of these bars, but insulated from them, is a bridge of similar shape to those employed on the manholes of boilers. The conductors pass through a hole in the centre of this bridge, and may be tightened up by any of the means described in a previous specification, No. 7655 of 1888. Claims: (1) Insulator carriages running on rolling supports in underground conduits, having insulator supports for frames which carry rotatory insulators as supports for the copper tape conductors; (2) in carriages to run in underground culverts or tubes as supporters of conductors of electrical energy, the employment of fixed insulators connected together by frames serving as supports for rotatory circular insulators having side flanges and centre roller, forming grooves to receive the conductors; (3) in means for conducting electrical energy the combination of an underground culvert or tube, with carriages provided with fixed insulators, connecting frames, and rotatory insulators with means for clamping and straining the conductors; (4) the combination of parts of conduits, guide, and carriage for copper tape conductors so as to adapt them for preserving their hold of such tapes in straining and transforming the line of strain of such conductors; (5) the general arrangement and combination of the various parts of apparatus for conveying electrical energy.—No. 11589. July 20th, 1889. 8*d*.

CORES FOR ELECTRICAL APPARATUS.—*W. P. Thompson, Liverpool. (The Westinghouse Electric Company, Pittsburg, U.S.A.)*—The object of the invention is to reduce to a minimum the spaces occupied by the insulation in cores, and at the same time to provide a method of manufacturing the core which will secure the required insulation between the lamenæ and also cheapen and improve the construction. Plates of the required size for building up the core are first stamped from sheets of suitable magnetisable soft iron. These plates are then subjected to an annealing process, which is carried to such an extent that a thin film of oxide is formed over their entire surfaces, and over also the rough edges produced by the stamping process. The core is then built up by placing these plates side by side. The film formed on the plates is chiefly magnetic oxide, and this is found to be such a poor conductor as to practically effect the insulation of one metal plate from the other. It is, however, more or less magnetised, so that it serves, when the plates are placed together, not only to insulate them, but as a magnetisable material for the core, thus combining two desirable qualities. At the same time the insulation is exceedingly thin. The annealing process is carried out as follows:—The plates are arranged in small piles in a suitable annealing box. The box is then placed in an oven and gradually heated. This step in practice usually occupies from six to twelve hours. When the proper temperature has been reached it is kept approximately constant for a sufficient time to produce the required effects. This may be varied in different instances, but it is usual to so heat the plates for twelve hours. They are then allowed to cool gradually, the heat being gradually decreased. This may occupy a somewhat greater length of time, say from twelve to twenty-fours. The gradual cooling secures thoroughly annealed soft plates. The oxide is very firmly attached to the surface of the plates, and can only be removed by attrition, so that the plates may be handled without special care and without endangering the insulation. Four claims are made.—No. 11046. July 9th, 1889. 8*d*.

ELECTRIC CUT-OUTS.—*W. E. Heys, Manchester. (N. & J. Chaize, Paris.)*—The apparatus is constructed to open the circuit below the surface of a liquid such as water which possesses a comparatively high resistance. The presence of the liquid, whilst it may not prevent the formation of an arc or spark, effectually prevents the localisation of any heating and the burning of the contact pieces. The accompanying illustration shows a practical application of this invention to the regulation of an electromotor by means of a pendulum governor. A is the governor which is driven by the motor. When the current attains a pressure sufficient to drive the motor at a speed greater than is desired, the balls B of the governor rise by centrifugal force and depress the spindle C in the same manner as when a similar governor is used with a steam engine. The lower end of the spindle C rests upon the end of a lever D, which carries at its opposite end the vertical rod or circuit interrupter G adjustably secured by the nut F. In a vessel E filled with water or other suitable fluid there is immersed the contact mass H, which forms the terminal of one conductor, whilst the rod G forms the terminal of the

Industries.

other conductor, so that when G is in contact with the mass H the circuit in which the motor is included is closed, but when G is lifted out of contact with H the circuit is opened. Thus when the spindle C is depressed the circuit is interrupted. Claims: (1) In an apparatus for opening and interrupting an electric circuit, the combination and arrangement of a fixed conductive mass immersed in water or other suitable fluid, and connected to one terminal of an electric circuit, with a conductor connected to the other terminal of the circuit and to a lever or device for lifting it out of contact with the fixed mass below the surface of the fluid, substantially as and for the purpose described; (2) in an apparatus for opening and interrupting an electromotor circuit, the combination and arrangement with a governor driven by the motor of a lever operated by the governor, a contact carried by the lever, which contact dips below the surface of a fluid such as water, and is connected to one terminal of the motor circuit, and a fixed contact immersed in the water or similar suitable fluid, and connected to the other terminal of the motor circuit, substantially as and for the purpose described and as illustrated.—No. 12135. July 31st, 1889. 6*d*.

MISCELLANEOUS.

MAKING HOLLOW WARE.—*J. R. Thame, Boxmoor, Hertfordshire, & H. Sanguinetti, London.*—The ware is formed of paper or like pulp. The appliance employed has an inner perforated shell, or former, covered with wire or other gauze, and an outer solid shell arranged to be drawn away from the inner and perforated one. Both shells have flanges at one end, by which they are held in place. The space between the shells forms the mould for the hollow ware or bucket. Between these shells the pulp is introduced by a force pump, a vacuum at the same time being produced in the inner shell. By this means the pulp is to some extent cleared of its water. When the space between the two shells is filled, the pulp supply is discontinued and air pressure applied to either side of the partially formed pulp article. The pulp is thus pressed into a seamless and homogeneous body, and can be removed from the mould. The machine may be continuously shaken whilst the pulp is being forced in, to cause the fibres to more effectually mat together. Claims: (1) Forming hollow ware articles from paper or like pulp contained in a suitable mould by the use of compressed air to compress the pulp and force out the water aided by compressing surfaces and the use of vacuum; (2) the combination or arrangement and use of parts of apparatus for extracting the moisture from paper pulp in order to form hollow ware articles with the aid of compressed air or compressed air and vacuum as described.—No. 10911. July 6th, 1889. 8*d*.

FIXING POSTS.—*W. H. Thomson, New York, U.S.A.*—This describes a base or support for telegraph, gate, and other posts, which base is stiffened and held in place by detachable cross stakes or pins passed obliquely through the base and driven into the ground. The base may be of any suitable form or material in a single piece, and preferably formed with a pointed or tapering lower end to enable it to be driven into the ground. At its upper end the base is formed with a socket to receive the lower end of the post, and in its sides are oblique passages through which the pins are inserted. The pins are flat with tapered ends. To fix the post the base is driven into the ground until the upper openings for the pins are just above the surface of the ground. The pins are then inserted and driven into the earth until their heads are flush with the post. Greater rigidity and security is obtained by driving one pin in with its flat side uppermost and a second with its thin edge uppermost. These two pins are threaded through the post from opposite sides, and the second pin passed through a slot in the first after the first has been driven home. The pins are thus driven in in pairs, and each pair is made to cross the one above and below it. Seven claims are made.—No. 9992. June 18th, 1889. 8*d*.

Copies of the British specifications may be obtained on application to H. READER LACK, Esq., Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every 10d. or fraction of 10d. Remittances exceeding one shilling must be made by Post Office Order.

BURNHAM'S "STEAM LOOP."

We recently had an opportunity of inspecting working models of a new invention for economising the fuel used in steam boilers and steam heating apparatus, by what the inventor (Mr. Burnham) calls the "steam loop," or "steam sweep." By means of this appliance condensed water can be raised from a low level back to the boiler, which is situated at a higher level, without using either a pump or injector, and, paradoxical as it may appear, the water flows back as if it were under the influence of gravity. Hitherto it has been customary to fix the engine at a higher level than the boiler in order that the condensed water might flow back into the boiler by gravity, but by means of this appliance the difference of level is found to be quite unnecessary.

The apparatus has been widely used in the United States for the last eighteen months. Amongst the users are the Worthington Pumping Engine Company, New York; the Pullman Car Company, Chicago; the Westinghouse Machine Company, Pittsburg, Pa. The patent rights for the United States and Canada have been acquired by Messrs. Westinghouse, Church, Kerr, & Co. The apparatus is now being tried by Messrs. Armstrong, Mitchell, & Co., Newcastle-on-Tyne, and other firms in this country. The consulting engineer is Mr. Charles Blagburn, 150, Leadenhall Street, and the sole licensee, Mr. John Gillespie, Leadenhall Buildings, Leadenhall Street. The action of the steam loop will be understood from the diagram Fig. 1, which shows its application to a steam coil as used for heating purposes. The loop consists invariably of three parts—the vertical pipe from the coil, called a "riser"; the horizontal portion, called the "horizontal"; and the vertical pipe entering the boiler, called the "drop-leg." To work the steam loop, the valve A on the boiler (Fig. 1), the valve B on the coil, and the blow-off valve C are all opened, the valve D being closed. As soon as all air and water are discharged and live steam blows out, the valve C is closed; then the steam gauge E shows pressure in the drop-leg. The latter is allowed to fill with water, and as soon as the steam gauge E shows a slight excess of pressure over steam gauge F on boiler the valve D is opened and the water is forced out of the drop-leg into the boiler until the pressure gauges E and F show the same pressure. The difference between the gauges G and F shows the loss of pressure by condensation, which must

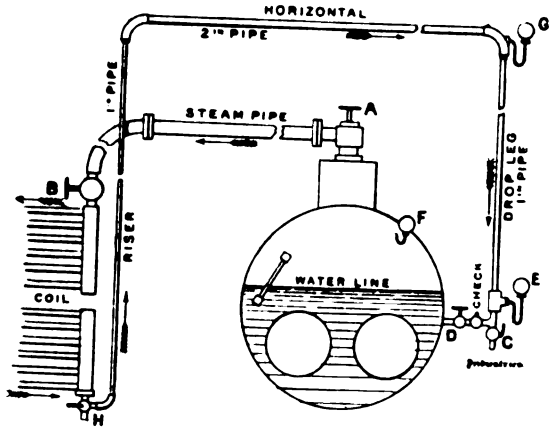

Fig. 1.—Application to Steam Heating Coil.

be made up by the rising of the water in the drop-leg. This difference multiplied by 2·3 will give the height of a column of water in the drop-leg above the boiler water-level, and provision must be made to have the length of drop-leg enough to allow for this column. Fresh water coming over cannot stay in the drop-leg, but flows continuously into the boiler. The valve H is a three-way drainage cock. The flow of the steam is indicated by arrows. Steam, as is well known, always flows to the point of lowest pressure, and the pressure begins to fall directly it leaves the boiler, partly by condensation, and partly by friction. The point of lowest pressure will be at the boiler water-level in the drop-leg, and, as a consequence, there is a constant flow of steam towards this point, which flow continues as long as condensation goes on. This sweep of steam carries along with it all the water formed by condensation or contained in the steam, at first in the form of a thin film swept along the inner surface of the loop, and afterwards, when the accumulation of water is sufficient, in the form of small slugs or pistons of water, which completely fill the pipe at intervals, travelling rapidly towards the point of lowest pressure and forming a column of water above the boiler level. This accumulates until it reaches a height which would balance the difference of pressure. As the loop still continues to bring over water, it follows that as fast as a slug or piston of water is deposited by the steam sweep on the top of the column, it overbalances

BURNHAM'S "STEAM LOOP."

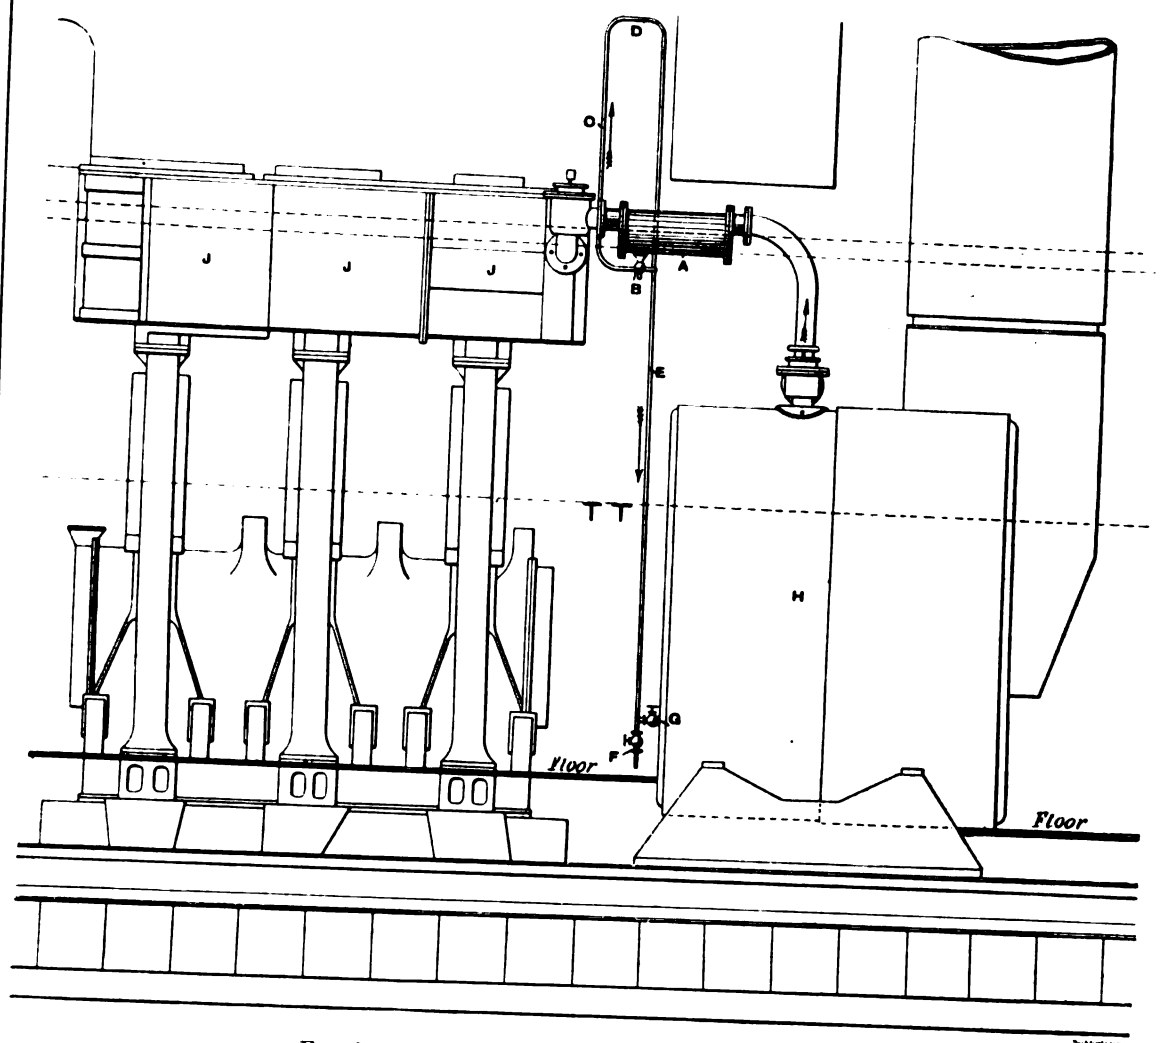

Fig. 2.—Application to Triple-Expansion Engine.

the equilibrium, and an equal amount of water is discharged from the bottom of the column through the check valve into the boiler. The water is thus returned to the water with the minimum loss of heat.

When the steam loop is used in connection with a steam engine, a separator is employed immediately in front of the engine, which catches the water of condensation, as well as that carried over by the steam. The "riser" of the loop is connected to the separator, and the water carried back to the boiler in the manner described above. Fig. 2 shows the application of the steam loop to triple-expansion engines, where A is the separator on main steam pipe, B three-way drainage cock, C riser of steam loop, D horizontal steam loop, E drop-leg steam loop, F blow-off cock, G boiler check valve, H main boiler, J J J steam cylinders. The economy of quickly returning to the boiler the water of condensation hot and under pressure in all uses of steam is generally admitted by all steam users. The appliance appears to fulfil this end in a satisfactory manner. It is remarkable in its simplicity, and there should be a wide field for its use in this country.

THE ROYAL AGRICULTURAL SOCIETY'S SHOW AT PLYMOUTH.

The Royal Agricultural Show was opened to the public on Saturday last. The weather was everything which could be desired, and the ground, rising from near the North Road Station, presented a most interesting sight. The town was gaily decorated with innumerable flags, triumphal arches, and decorations. Last year the Society celebrated its Jubilee, and the number of exhibits and the ground covered exceeded the average. This year the average is maintained, but it would be unfair to compare the present show with that of last year at Windsor. The exhibits are numerous and interesting; all the chief makers of implements are represented; but they are content to repeat their stock types, which have now become settled. Novelties are the exception rather than the rule, and this is not to be wondered at when it is considered how rapidly one show succeeds another. Implement makers hold high carnival twice a year, once in mid-winter at the Smithfield Show, and once every mid-summer at the Royal Agricultural Show. Probably at the summer meeting dairy machinery figures more largely than at the winter show.

Messrs. Clayton & Shuttleworth's exhibits are up to their usual excellence, and comprise portable and traction engines, thrashing and chaff-cutting machines, sack lifting and running barrows, besides lifting chocks and screw-jacks. Messrs. John Fowler & Co. show their 10 h.p. compound ploughing engine, fitted with two speeds, steel gearing and drums, and self-acting coiling gear; an 8 h.p. agricultural engine, and a 12 h.p. horizontal engine; also an assortment of portable railway appliances. Messrs. J. & F. Howard, Bedford, have a large number of ploughs, harrows, hoes, haymakers, and other implements; they also show again their specimens of portable railways and appliances, and a double-side tip-waggon. Messrs. Ransomes, Sims, & Jefferies, Limited, Ipswich, exhibit a large collection of their manufactures, including a 10 h.p. compound small type engine and boiler fitted with an automatic governor expansion gear; the steam chest of the high-pressure cylinder is fitted with a sight feed lubricator, and the jacket is drained by a steam trap. The cylinder and working parts are mounted on a strong wrought-iron frame, and are thus specially adapted for export. The ease with which they are fixed is a marked feature; the boiler can be detached readily from the engine, and the girder frame taken to pieces, thereby rendering the weight of the packages for transport exceedingly convenient. Messrs. R. Hornsby & Sons, Limited, Grantham, have a good show of ploughs, pulpers, reapers, and mowers. They also show an 8 h.p. traction engine constructed to work at 120lb. pressure per square inch, the gearing throughout being of crucible cast steel; also an 8 h.p. and a 6 h.p. portable engine, each with a second lock-up safety valve in addition to the usual fittings. A 4 h.p. vertical engine and boiler on wheels is also shown, arranged so that the fly-wheel can run clear of floor: Messrs. Charles Burrell & Sons, Limited, Thetford, Norfolk, in addition to their other exhibits, show their single-crank system of compound road locomotives. The high-pressure cylinder is placed directly over the low-pressure cylinder, and the piston rods of both are connected to one long crosshead, which is equal in length to the distance between the centres of the two cylinders. The steam, after leaving the smaller cylinder

THE ROYAL AGRICULTURAL SHOW AT PLYMOUTH.

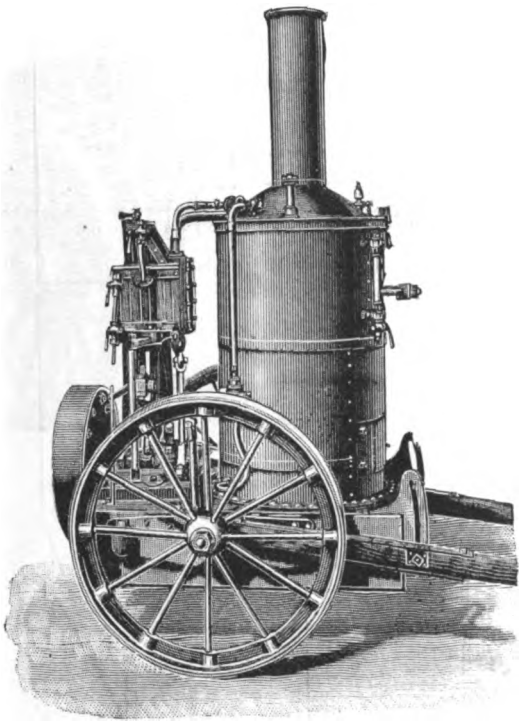

FIG. 1.—MESSRS. SIMPSON, STRICKLAND, & CO.'S SMALL PORTABLE ENGINE.

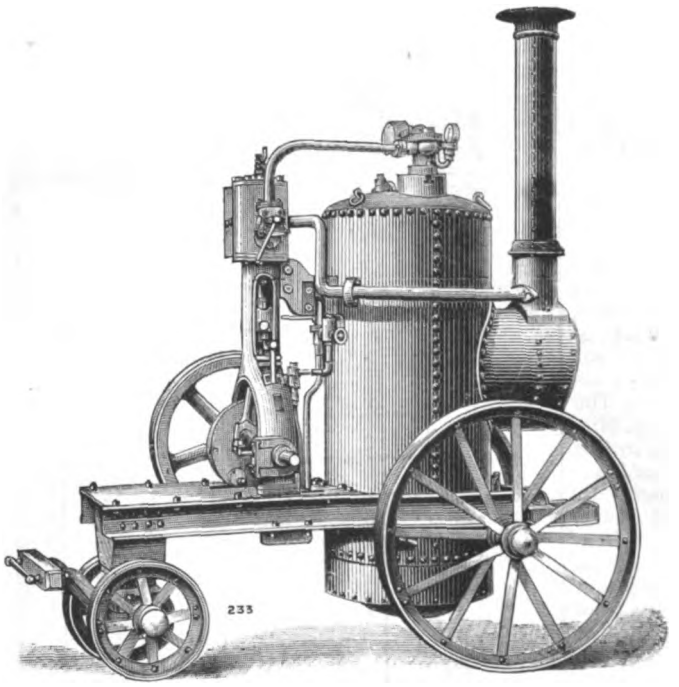

FIG. 2.—MESSRS. E. R. & F. TURNER'S SMALL PORTABLE ENGINE.

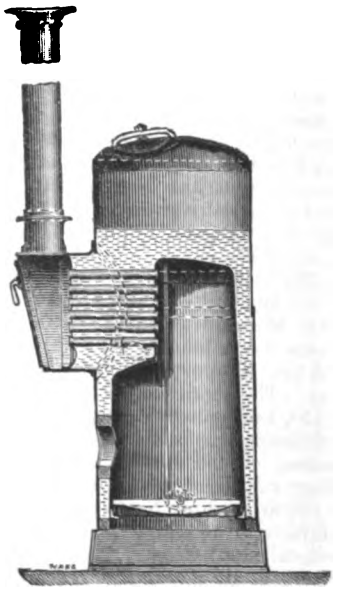

FIG. 3.—SECTION OF BOILER OF MESSRS. TURNERS' ENGINE.

passes directly into the low-pressure cylinder, all clearances being filled up as closely as possible. The slide valves of both high and low pressure cylinders are coupled together and driven by one link motion, so that, beyond having two extra glands to pack, there are no more parts requiring attention than in the ordinary engine with one cylinder.

Messrs. Davey, Paxman, & Co., of Colchester, exhibit two steam engines of the portable type, both of which have been selected by the Jurors for driving the various machines sent for competition. They also show a 16 h.p. undertype engine, a horizontal girder engine, and their "Essex" vertical boiler.

Messrs. Priestman Brothers, Hull and London, exhibit a 2 h.p. horizontal petroleum engine, with oil cistern, vaporiser, air pump, igniting apparatus, and all details for preparation of oil vapour, including separate water vessel, with circulating pump. An 11 h.p. portable oil engine, mounted on wheels, is shown, driving one of Wallis & Steven's thrashing machines, for which purpose it appears to be very suitable. This engine is similar in construction to the 7 h.p. engine shown and illustrated by us last year, as is also a 5 h.p. engine, which has been awarded the first prize by the Royal Agricultural Society for light portable motors up to 5 brake h.p. Messrs. Priestman also show models of their patent dredging and excavating machinery.

The first prize for steam engines up to 5 h.p. using solid fuel has been awarded to Messrs. Simpson, Strickland, & Co., Dartmouth, for a vertical engine and boiler illustrated in Fig. 1, above. This engine has been designed for the light work of a farm, such as cutting chaff, pulping roots, and elevating hay. It is mounted upon a pair of wrought-iron wheels, and is so light that a small-sized horse can readily draw it about, its draught not exceeding that of an ordinary farm cart. This firm also exhibits a very neat steam launch with quadruple-expansion surface condensing engines.

The second prize for steam engines using solid fuel has been taken by Messrs. E. R. & F. Turner, Ipswich. This is illustrated in Figs. 2 and 3, and is a $2\frac{1}{2}$ h.p. vertical portable called "The Gippeswyk." As will be seen, it is carried on a light wrought-iron frame mounted upon wrought-iron wheels, and fitted with a pair of shafts, so that it can be readily transported.

Messrs. Avery, Birmingham, show two novel weighing machines. The first (Fig. 4) is a weighing crane, which enables the weight of a body suspended from the crane to be ascertained while it is being lifted. The crane can be used for ordinary purposes without reference to its weighing properties, the latter only being used when the levers are put in gear, which is effected by a very simple arrangement. The recording lever or steelyard is contained in a box with a falling lid, which can be locked when the weighing mechanism is not in use. An arrangement of chains preserves the balance of the beam, the amount of chain being equally distributed on each side of the crane at all times. There are two pendant chains with weights at their extremities; one of these chains is intended to carry the body to be weighed, while the other acts as a counterweight, rising as the freight chain falls and falling as the freight chain rises, thereby keeping the apparatus in constant equilibrium. The other novelty is a weighing machine and tip-cart combined (Fig. 5), which is made as if the body of a cart were fixed to an ordinary platform weighing machine, and the wheels to the frame. The cart can be used for all ordinary purposes, and it is balanced so that when empty the steelyard registers zero, the recording steelyard only weighing the load in the cart. This is in front of the cart. To effect a weighing the sliding poises are moved along the steelyard. If a printed record is required it can be obtained by inserting a ticket in a slit in the larger poise and depressing a handle. On withdrawing the ticket it will be found to be embossed in bold figures with the weight of the load.

Prizes for disintegrators were taken by the Hardy Patent Pick Company, Limited, Sheffield, and by Messrs. W. N. Nicholson & Sons, Newark. The machine, for which the first prize was awarded, is known as "The Devil" disintegrator. The conditions of award for this are that it must be capable of being worked with a portable or traction engine not exceeding 20 brake horse-power. The machine combines the percussive action of ordinary high-speed disintegrators with a grinding action, which progresses step by step, and gradually reduces the material dealt with to the degree of fineness required. It consists of two grinding rings, one fixed, and the other revolving. Each grinding ring has teeth upon its face, arranged in concentric circles with spaces between them, the teeth and spaces decreasing in size towards the outside edges of the grinding rings, the teeth of one ring passing between the circles of teeth on the other. The patterns of grinding rings generally used are capable of dealing with a wide range of materials, such as grain, bones, rags, clay, pepper, &c. Where one class of material only is required to be ground the grinding rings are specialised to suit the work. For granulating a brittle material grinding rings with moderately coarse teeth are used, but for reducing the material to a fine powder rings with a large number of fine teeth are preferred. The revolving disc is driven at a speed of 800 to 1,000 revolutions per minute. The materials are introduced through a hopper into the centre of the machine, and all material must pass between the grinding rings before reaching the outlet, an opening at the bottom of the casing.

The second prize disintegrator, by Messrs. W. N. Nicholson & Sons, is shown by Fig. 6. It is on a different principle from "The Devil," the material to be acted upon being crushed between two pairs of rollers, composed of hardened discs of tough annealed crucible cast steel, firmly bolted together. An effective way has been adopted of securely interlocking the discs of which the rollers are formed, so that in case of breakage the pieces are held by the discs on either side of the broken one and are prevented from falling out and causing serious damage to the rollers or gearing. The discs when bolted together are as substantial as if made in one solid mass. The rollers are run at different velocities; they are thus rendered self-cleaning. The upper pair of rollers have chisel-pointed teeth, the lower pair have more pointed teeth. These deliver and work against corresponding toothed "concaves," which embrace the lower half of the periphery of one or both rollers. To prevent breakage the rollers are provided with strong boxed springs at each bearing, whilst the concaves are safe-guarded by a weighted lever, the pressure on which can be regulated, and a finer or coarser sample produced at pleasure. By the removal of the weight the concaves can be thrown out of use. Messrs. Nicholson have also an excellent collection of small implements, of which their "Snapdragon" self-acting horse rake is new this year. The principles attempted in this implement are the abolition of springs, the prevention of re-locking before delivery of load, a novel snap arrangement by which it is prevented from again coming into gear after delivery of the load, the trussing of the part of the rake frame which is liable to be strained by careless working, and an improved form of stripper for clearing the teeth. The action of the rake is as follows:—A slight and short pressure of the driver's foot on the pedal when riding, or an easy lift of the back lever if walking, allows the pawls to engage with the ratchet wheels. At the same time the re-locking of the rake by the horse stopping or backing before the load is delivered is prevented by wings or stops formed on the rake frame, against which the pawls abut. The rake having delivered its load, the teeth fall by their own weight with a steady descent to get well through and under the hay, and so ensure a good load and clean raking.

Mr. J. Harrison Carter, of Mark Lane, London, has a fine exhibit of his disintegrators in six sizes. We give an illustration in Fig. 7 of one of these machines. This will pulverise three tons of bones per hour. The variety of substances for which disintegrators are used constitutes a striking feature, and accounts in some measure for the variety of these machines now in the market. Mr. Carter informs us that his disintegrator will pulverise every possible substance that can be got into the machine. The list is too long for us to give it in full, no less than seventy materials being enumerated. The samples shown us clearly prove that the machine does its work effectively. To mention vegetable products, metals, bones, and clay gives an idea of the range of substances which are dealt with by disintegrators. In Carter's machine the material is fed in at the periphery of the grinding chamber, and, falling on the extremity of the beaters, which travel at the rate of three miles per minute, is pulverised by them by being beaten against the serrated chilled iron linings of the upper half of the chamber or the steel bars of the screens which form the lower half. The beaters are made of Lowmoor iron and faced with steel. They are

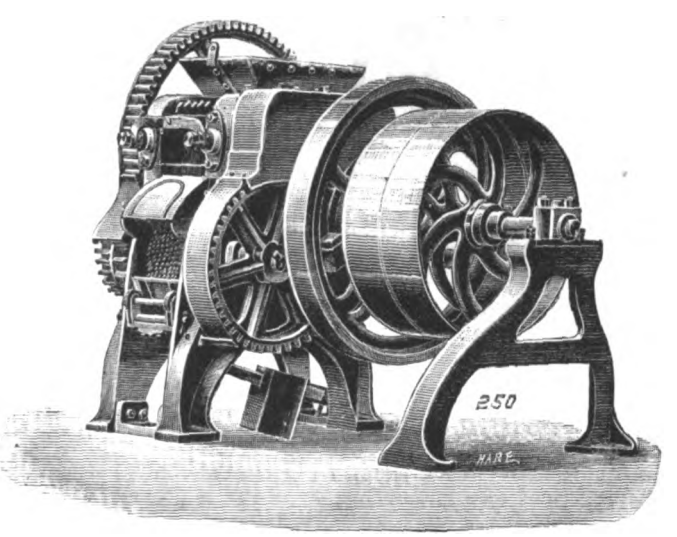

Fig. 6.—Messrs. Nicholsons' Disintegrator.

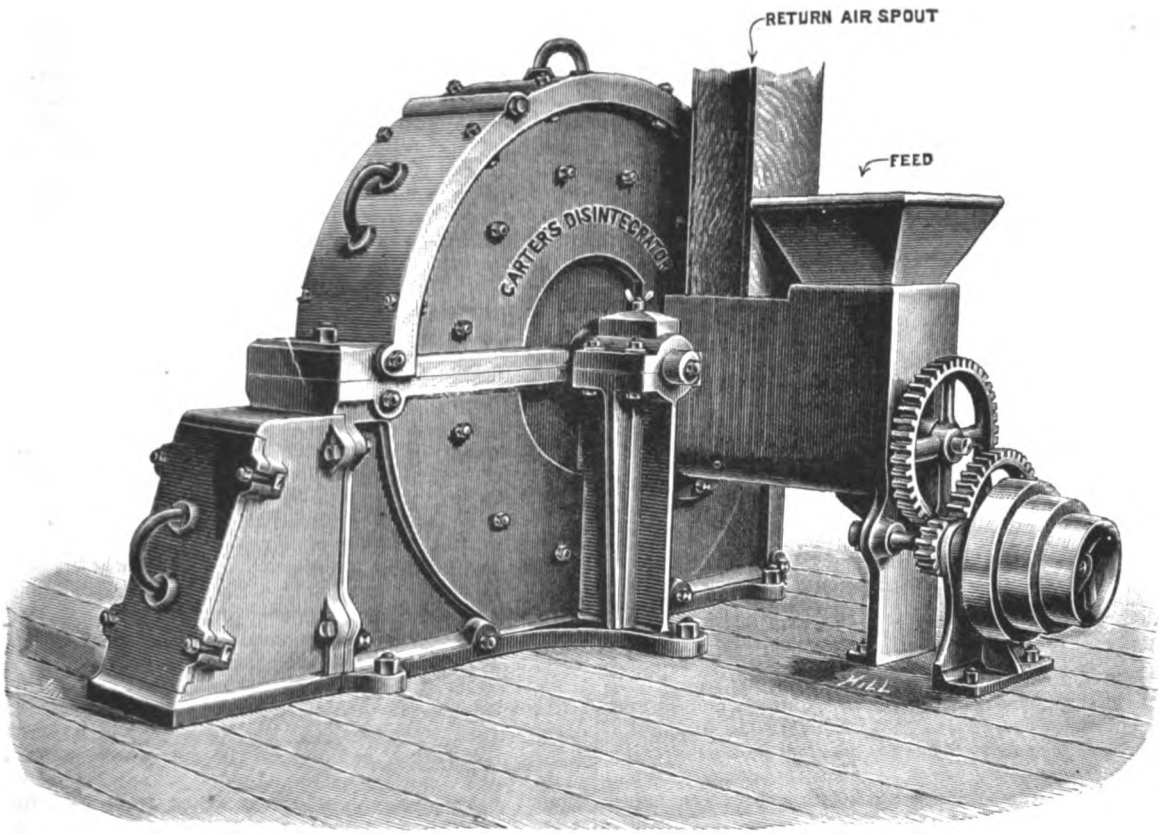

Fig. 7.—Mr. Harrison Carter's Disintegrator.

set so that in running they travel in three parallel paths, thus covering the whole available space of the beater chamber. A novelty at Mr. Carter's stand is a magnetic separator and dynamo. This machine is employed to separate pieces of iron, which frequently are found amongst bones when they are bought in bulk, marine store dealers not being careful enough to prevent the mixing, which invariably takes place between the producers and the grinders. The bones are fed upon an inclined plane, which receives a rapid series of impulses, causing the bones to travel downwards. At the bottom they pass over an irregular roller, which has a large number of electromagnets distributed throughout its length and circumference; these magnets seize hold of any iron which passes over the roller, and leave the bones to fall into the feeder of the disintegrator. The pieces of iron are carried round by the roller past a partition, when the magnets are demagnetised and the iron falls off into another receptacle. This is done continuously, the magnets being alternately magnetised and demagnetised during the revolution of the roller.

Mr. W. H. Coward, Bath, exhibits two of his new slow-motion rapid pulverising mills. This pulveriser consists of a revolving drum, containing an edge runner running at the bottom of the drum. The runner is thus caused to roll in contact with the periphery of the drum, and to crush or pulverise the material brought under its action. The edge runner is carried by a shaft at a lower level than the shaft driving the drum. After the material has passed under the runner, it is carried up by two circles of wedge-shaped cups, fixed on each side of the drum; the edge runner being of less width than the drum allows room for these cups. The cups, as they pass the centre, reverse their position, and the material falls again and again until it is fine enough to pass a screen, through which the finished material is drawn by an exhaust fan. Allied to disintegrators are stone breakers: these are represented by Baxter's knapping-motion stone breaker and by the Blake-Marsden machine. The latter is of the lever hand-hammer motion type; it is fitted with automatic screening apparatus, and mounted on travelling wheels. The machine is driven by an 8 h.p. steam engine, and is capable of breaking 10 to 15 tons of road metalling per hour.

Amongst the exhibitors of the smaller class of machines, Messrs. R. Hunt & Co., Colne, Essex, have a good show, their various grinding mills being simple and compact. This little mill is driven by a two or three-horse gear or by a small engine. It is fitted with safety lever and weight, which instantly releases any hard substance without injuring the plates, and has an adjustable slip for regulating the feed. It is fitted with a hook and chain for raising the lever and weight and releasing the grinding surfaces when the machine is running empty. The bevel gear being arranged for gaining speed, 150 to 200 revolutions per minute is ample for its maximum speed. The grinding surfaces

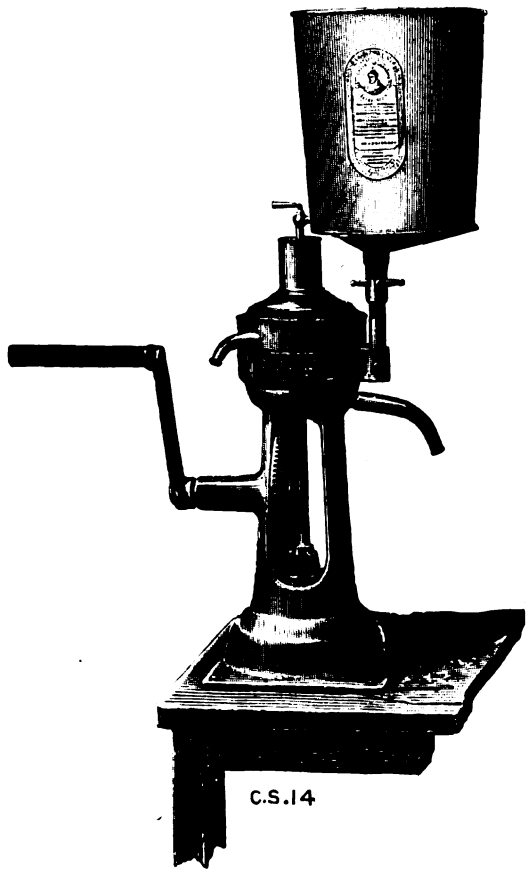

FIG. 1.—GENERAL VIEW.

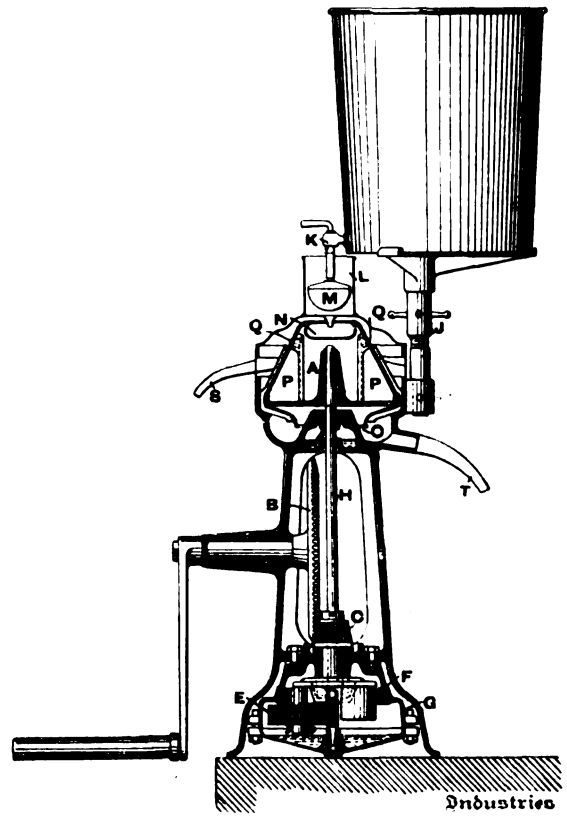

FIG. 2.—VERTICAL SECTION.

consist of two flat circular plates, so grooved and fluted that the corn or seed entering at the centre is ground before passing out at the edges. The pitch can readily be adjusted to grind into fine or coarse meal.

Mr. Davies, of Gwellath, Cury, Cornwall, exhibits his new patent revolving divider, which was first shown at Smithfield last year. It consists of a long fluted conical roller, driven by a chain from the self-raker or binder platform wheel, and as it revolves the grain, which under adverse circumstances clings to the ordinary stationary divider, is lifted up, and is thus cut as easily as unlaid grain. This appliance can be fitted to any harvester. The Agricultural Mill Company, Lawrence Pountney Hill, London, show Andrew's new corn grinding mill in three sizes. At the same stand we notice that Mr. Joseph Westwood, Millwall, exhibits the well-known Hawksley treads so much used at railway stations.

Mr. J. Best, Plymouth, shows a novel automatic stop and starting valve, "The Estover," for starting and stopping small water wheels and hydraulic rams, where there is a continuous stream, but which is insufficient to drive a machine continuously. Mr. Best allows the water from the stream to flow into a tank, where it is stored until there is water enough to work the wheel or ram for a few hours. The valve then acts by opening a connection between the tank and the machine, which works until the supply is exhausted, when the valve shuts and the storage begins again. The principle is shown by Fig. 8. The rivulet water runs into the tank at M; as the water rises it lifts the guided float D, which has a square prong E attached to one side and sliding in a loop F during the time of filling; the loop F has adjustable screws; it is attached at the bottom to a gun-metal valve A, with inlet at the bottom, and sliding plug B, with stop bars C C. This valve A opens communication with the machine to be worked by admitting water to the drive pipe L. At the top the link F is attached to a beam lever I I with a counter-balance ball J; as the link rises or falls, so it turns the beam lever to one side or the other; the action is accelerated by a store of mercury contained in a steel cylinder G, the mercury flowing from one side to the other as the beam is lifted or lowered. The sensitiveness of the beam can be regulated to any degree by the position of the cylinder containing the mercury, as the hands H H enable the cylinder to be fixed anywhere on the beam.

Dairy machinery is well represented at the show by a number of stands, the Aylesbury Dairy Company having one of the finest exhibits. The Redcliffe Galvanised Iron Company show a small but useful improvement to milk cans. Three small wheels fitted with indiarubber tires enable the cans to be run along easily instead of twisting them along their edge in the usual manner. They also exhibit a new departure in the shape of the cans, making them flat on one side, to enable them to be more easily carried on a man's back. Mr. H. G. Vacher, Winchester, exhibits a collection of lift pumps, hydraulic rams, and turbines. This type of turbine is for use in places where it is preferred to drive by belt or rope. It

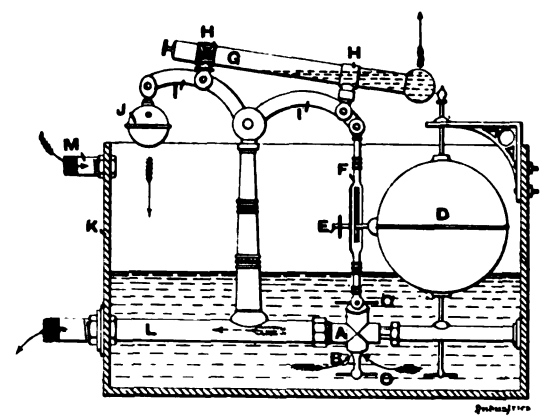

FIG. 8.

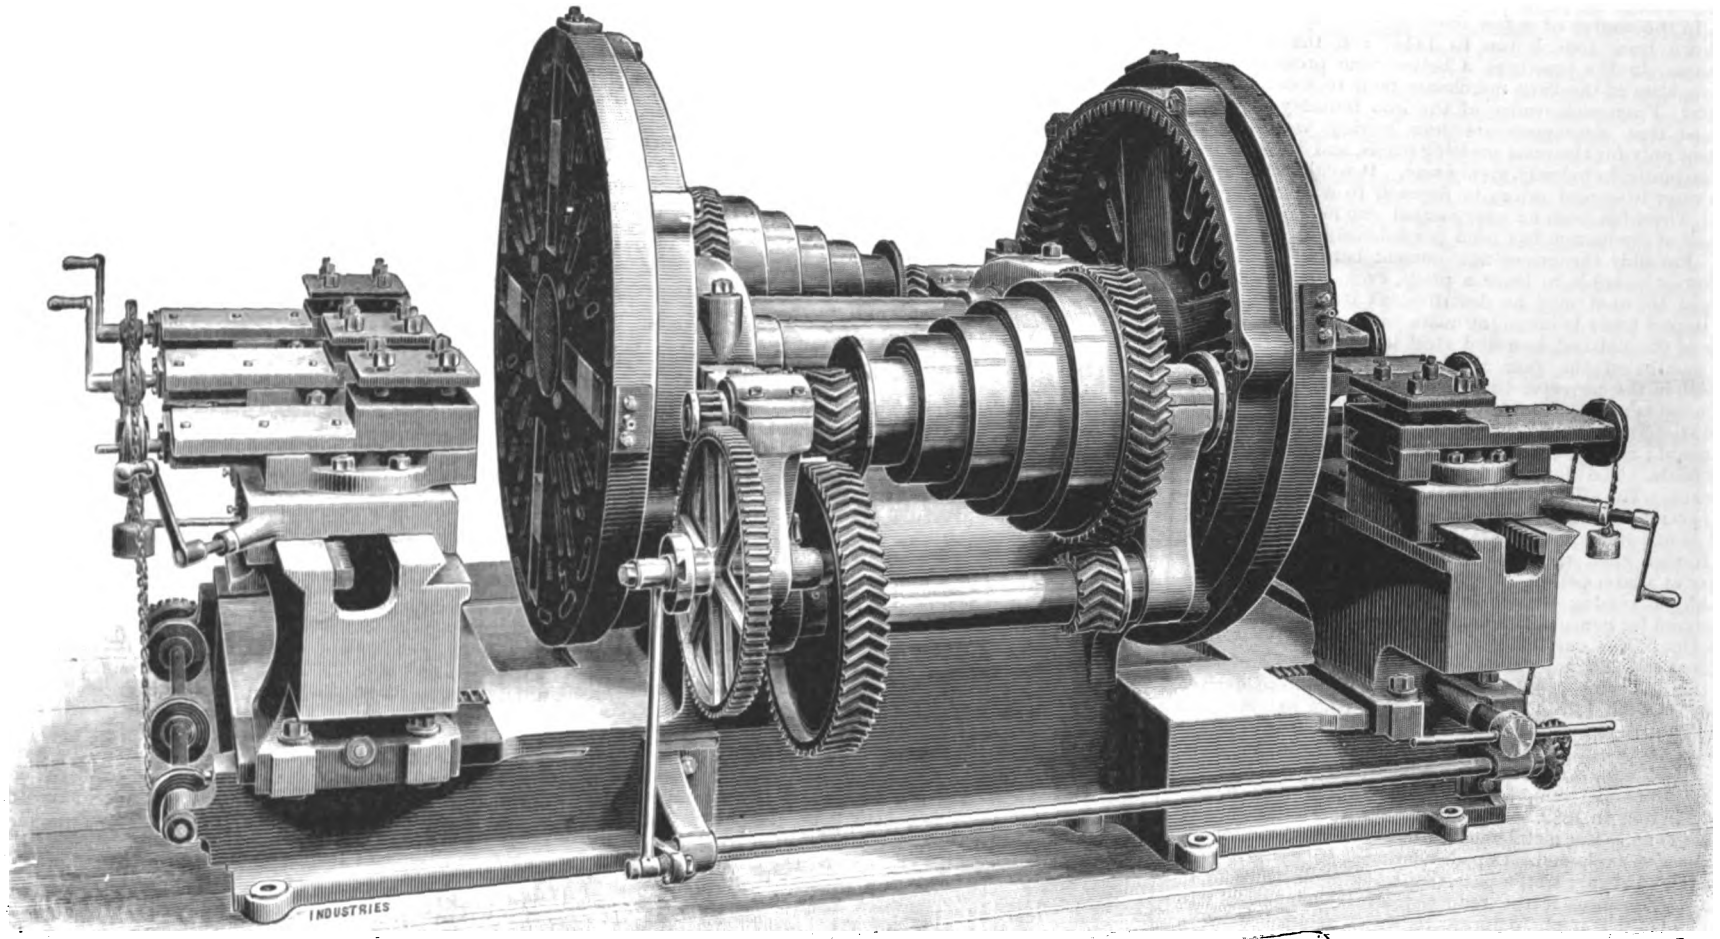
consists of a revolving wheel with curved buckets, which is divided in the centre by a disc, and has a right and left outlet for the water. It is fitted inside an annular guide case provided with stationary guide blades which direct the inflowing water against the buckets of the wheel. The guide blades are fitted with wedge-shaped tongues, which when open lie in recesses in the guide blades. The tongues have a small shaft passing through the top of the guide case above mentioned. The shafts are fitted with arms, which are connected together by a ring, so that, in the event of one tongue moving, all of them move in the same direction. The ring is controlled by a counterbalancing weight or spring, which always tends to keep the tongues closed. When part of the load is taken off the turbine, the wheel commences to rotate at a higher speed, and the centrifugal action of the water in the wheel, reacting on the inflowing water, reduces the pressure on the face of the tongues, so that they will be at once partially closed by the counterbalancing weight acting through the ring and arms before mentioned, but as soon as the speed of the wheel is reduced the centrifugal action ceases, and, the pressure of the incoming water being restored, the tongues return to their seats.

Messrs. Powell Brothers & Whittaker, Wrexham, show, in addition to their agricultural implements, a specimen of their "Minerva" rock drill. In this drill a piston rod is provided with two pistons, each of which works in connection with an independent set of parts formed in the cylinder of the drill. The piston rod with the tool receives a rotating motion by means of a twist bar which passes through the other piston. At the outer end the twist bar carries a ratchet wheel in connection with which are double-ended pawls, which, whilst permitting the rotation of the ratchet wheel in one direction, prevent any movement in the direction opposite. Messrs. Barnard & Lake show their thatch-making machines, which have been out a few years; they also show a lighter and modified pattern, with several minor improvements, including the introduction of steel tubes for main frame in lieu of the present heavy cast-iron one. Messrs. Tasker & Sons, Andover, show a double-action well machine combined with a force pump. By the use of this machine one man is able to raise water from a well 150ft. deep and force it to a tank 50ft. above the level of the machine. It is constructed wholly of iron, and stands on an iron curb. A pulley is placed over the upper part of the machine, over which a rope or chain passes with a bucket at both ends, so that when one bucket is delivered at the top full the other is being filled at bottom of the well. A tank provided with two catches is placed on the curb plate, so arranged that the buckets are automatically tilted over and the contents emptied into the tank. A force pump worked from the same handle as the well machinery forces the water from the receiving tank to where it is desired for use. Mr. H. Sykes, London, shows his "Bankside" portable pumping-engine, consisting of vertical boiler, high-speed engine, and centrifugal pump, mounted on wrought-iron frame, with wheels and shafts. Messrs. John Cowley & Son, Hyde, show a collection of screwing machines, including a handy little tool recently designed for screwing pipe bends, which cannot be done with the ordinary stocks and dies. By the introduction of bevel wheels the handle working the machine turns in a plane parallel to the longitudinal axis of the pipe, which it is thus enabled to clear. The makers state that a full thread can be cut at one screwing. A pair of extra wheels is provided for attaining additional speed when screwing the smaller sizes; pieces of pipe as short as 3in. can be screwed along 1in. at both ends without spoiling the thread or damaging the tube. For street or other outdoor work the tool should prove very useful. Mr. W. A. Stone, of Prague, Austria, again exhibits Dolberg's patent flexible narrow gauge railway, together with specimens of the rolling stock suitable for it. Messrs. Entwisle & Kenyon, Accrington, show a collection of vices, including a new one with a swivel jaw, by means of which a taper cotter can be held with the same facility that a parallel piece of iron can be held.

(To be continued.)

THE "VICTORIA" PATENT CREAM SEPARATOR.



OF late years the importance of the dairying industries has become more generally recognised, and as a consequence new dairies have been started, some as private enterprises and some as public companies. This industry has proved, when conducted on modern scientific methods, to be very remunerative. In some cases a number of farmers in a pasture district join together, and start a central "creamery" or "butter factory," where the produce of all is dealt with and converted into butter, or the cream is mechanically separated from the milk while quite new for immediate sale. Important among the inventions required is the centrifugal cream separator, by the use of which every particle, or rather globule, of the fat which goes to make butter can be extracted and quickly separated from the milk immediately it is taken from the cow. The old process causes from 2 per cent. to 5 per cent. of the cream to be left in the skim milk.

The illustrations (Figs. 1 and 2 above) show the "Victoria" hand-power cream separator, which has been invented and is manufactured solely by Messrs. Watson, Laidlaw, & Co., engineers, Glasgow. The "Victoria" separators are made in various sizes, the smallest size, which we illustrate, being capable of separating 20 gallons of milk per hour, and it can be driven with ease by a lad or girl. The largest size made at present separates 150 gallons of milk per hour, and is

Digitized by Google

DUPLEX TYRE TURNING LATHE.

CONSTRUCTED BY MESSRS. SHEPHERD, HILL, & CO., TOOL MAKERS, HUNSLET ROAD, LEEDS.

driven by a steam engine or other convenient motor. Fig. 1, on the opposite page, shows the small machine complete, fixed upon a table ready for action, and Fig. 2 shows the machine in section. The separation of the milk from the cream is effected in the "drum" A of the machine while running at a speed of about 7,000 revolutions per minute. The speed is attained by a gear which has a velocity ratio of 1 to 174 —*i.e.*, for one revolution of the handle the drum A makes 174 revolutions. The bevel wheel B gears with the bevel pinion C, which is fixed to the hollow shaft of the crank D. This crank is fitted with a pin which carries a double spur wheel E. The smaller of these gears with the teeth of the internal wheel F, which is fixed to the gear box G, while the larger wheel gears with the teeth which are cut in the end of the spindle H. It will, therefore, be seen that when the crank-shaft D is set in motion, the wheels E are caused to revolve rapidly about the pin which carries them, and that this motion is again multiplied when transmitted to the spindle H. In addition to this direct increase of speed have to be added the revolutions which the crank-shaft D makes about the spindle H.

We will now proceed to explain how the rich milk is fed into the machine, and how the separation is effected. The milk can or reservoir, which may be raised or lowered at will by means of the regulator nut J, is first filled, and the regulator tripod raised as high as it will go, so that the tap K projects only a short way into the float cup L. The tap is then opened, and the milk flows into the float cup quicker than it can escape from the small hole at the foot. This causes the float M to rise and press against the tap, and thus maintain a uniform head of milk in the float cup. This is necessary to ensure that the flow of milk into the machine is uniform and not intermittent. The distributor cup D receives the milk, and gives it the velocity of the drum A, into which it passes through a number of small holes in the sides under centrifugal pressure due to the velocity of the drum and distributor cup. The milk, of course, assumes a vertical position round the sides of the drum, and remains in the drum until the surface of the wall of milk reaches the bottom edge of drum O. It will be observed that there is a series of holes round the edge of the diaphragm or centre part of the drum, which makes a free passage between the upper and lower compartment of the drum. The drum is also provided with two vanes P. On the inner face of each a channel is cut; the top of this channel communicates with the outer collecting tray by means of the two small holes Q, Q.

These, briefly, are the mechanical details necessary to effect the separation of the milk from the cream, but to fully understand their application it is necessary to consider the action of centrifugal force. When a body, whether solid or liquid, revolves, it tends to move away from the centre round which it revolves. In the case of the cream separator the speed of rotation is so high, and the pressure inside the drum so great, that it necessitates this part of the machine being made of the strongest possible form and material, and it is, therefore, made of steel forgings. As the amount of centrifugal force which bodies exert depends partly upon their weight, it follows that the skim milk, being heavier than the fatty particles of the new milk, acquires a greater force outwards. This being so, the result is that the skim milk takes up the space next to the sides of the drum, and the cream forms an annular wall on the inner surface of the milk. No cream gains access into the bottom chamber of the drum, as the only channels are the small holes through the diaphragm as already mentioned, and these, it has been shown, are in a part of the drum occupied by the skim milk only. It will be seen, therefore, that the only outlets for liquid poured into the drum are either by the channels in the front of the vanes P P and the hole Q Q, or at the lower edge of the drum marked O. These points of escape are so arranged that the proper quantities of cream can escape out of the former and skim milk from the latter. A glance at Fig. 2 will show that the cream and milk are collected in channels as they overflow, and are led off by two different spouts. The cream spout is indicated by S, and the milk spout is shown at T.

An important feature of the "Victoria" cream separator is that the separation does not depend upon the accurate setting of adjustable tubes or valves, as is the case with some other types of machines. It further possesses the great advantage that by the raising or lowering of the feed-can by the regulator nut J, the cream may be discharged either thick or thin, at will, while still extracting the whole of the cream from the milk.

When the machine comes to rest the skim milk remaining in the drum flows into the bottom collecting chamber and out at the skim milk spout. This latter quality is peculiar to the "Victoria" separator.

Practical tests recently made with great care has shown that over 30 per cent. more butter can be obtained from a given quantity of milk when passed through this separator than with the old process of setting up and skimming by hand.

This separator is in use at the Edinburgh Exhibition at the working dairy of Mr. G. H. Pierce. It is also being exhibited at the Royal Military Exhibition, Chelsea.

DUPLEX TYRE TURNING LATHE.

THE tyre turning lathe shown above is adapted to turn and bore tyres 5ft. 6in. diameter. A strong headstock and foundation bed are cast in one piece. The headstock is fitted with two spindles, which run in gunmetal bearings, 9in. diameter. Each spindle carries a face-plate 5ft. 6in. diameter, which is fitted with four movable chuck jaws. The spindles are driven separately by five speeded cones, 5in. wide. In front of each face-plate a strong bed, 7ft. long, is fitted to the foundation, and can be moved to or from the face-plate by means of a rack and pinions. Three compound slide rests are fitted to each of these beds, and are made self-acting in both directions by ratchet wheels and levers, and each is worked independently. The two outside rests can be used for turning the tyres, and at the same time the centre one can be used for boring the boss. This lathe is made by Messrs. Shepherd, Hill, & Co., Hunslet Road, Leeds.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 24th June, 1890.

IRON.—Prices are again tobogganing in the Paris markets. In the course of a few days bars and joists have slid down from 156s. a ton to 144s., and the descent continues. In the provinces a better tone prevails, but these vagaries of the Paris merchants tend to weaken the markets. From each centre of the iron industry we are informed that consumers are now buying very little, sufficient only for the most pressing needs, and that prices are constantly, but slowly, giving way. It would, however, be an error to expect prices to descend to a much lower level. There has been no exaggerated rise in France, and the cost of production has been permanently increased of late. Probably the prices now current here in Paris are the lowest possible to leave a profit, even after coal has dropped to what may be described as its natural level. The import trade is becoming more active. The declared value of the finished iron and steel imported in the first five months of the year amounted to £95,280, against £81,440 in the corresponding period of 1889; that of iron of all sorts exported to £646,280, against £229,840.

COAL.—The strike of colliers in the St. Etienne district is at an end; but the effects will be felt for some time in the coal trade. The downward tendency of prices has been checked. The effects of the continued high prices of coal are severely felt in all the great manufacturing industries; and as one consequence is a large increase in the imports of foreign coal, the coal mining industry itself must suffer at a later period. English coal is being received in rapidly increasing quantities. The total import of coal delivered for consumption in the country in the first five months of the current year amounted to 3,490,695 tons, against 3,076,965 tons in the corresponding period of 1889. Of this quantity, 1,688,610 (1,425,926) tons were derived from England, 1,524,123 (1,339,222) tons from Belgium, and 275,464 (311,193) tons from Germany, the figures in parentheses representing the quantities received in the same period of last year. The coke imports, the bulk of which came from Belgium, amounted to 515,136 tons against 452,910 tons in 1889.

METALS.—The metal market has become an enigma not easy to be explained. Copper continues its upward movement at a steady trot, a pace that would be justified by the state of business if the reduction of the stocks in hand was what it is made to appear to be. It requires, however, a lively faith to accept the figures which are month by month put before us. Tin has gained a little in the course of the week, thanks to speculative buying. Lead and spelter are firm, with a distinctly marked tendency to rise. Amid such artificial conditions it is vain to attempt to forecast the course of business.

BERLIN, 23rd June, 1890.

IRON.—The business of the iron market is steadily declining. The trade of Upper Silesia is now giving way, buyers holding back for easier terms. The home demand for plates has greatly fallen off; but a brisk export business in this class of goods is kept up with Russia. Joists, too, are in good demand on export account. Manufacturers will be busy on old contracts for some months to come; but fresh orders are likely to become scarce. Founders, though they have plenty of work in hand, are already complaining of the scarcity of orders. During the last week the price of Silesian bars has oscillated between 195s. and 200s. a ton at the works, leaving off at the lower figure. Here in Berlin nothing has been done under 200s.; but the market is weak and evidently tending in favour of buyers. The latest report from Breslau describes the market as still very active for pig iron. This state of things may continue a few weeks longer. But evidently a quieter time is approaching. The export trade continues to shrink.

COAL.—The reaction in the coal market becomes more distinctly marked as the summer advances. Consumers are as reluctant to buy coal now as they were eager only a short time ago. This fact may in part be taken to indicate diminished activity in the manufacturing industries, but it must be borne in mind that the extraordinary brisk business of the coal market in the first four months of the year was largely due to the stocking of coal by consumers to protect themselves against threatened strikes. The Upper Silesian market is very dull, but prices are maintained at from 8s. to 8s. 6d. for large coal; from 7s. 3d. to 8s. for "nuts"; and from 4s. 6d. to 4s. 9d. for small, at the pits. To avoid accumulating stocks the colliery owners are working their pits only five days a week. The coke industry continues active.

METALS.—The changes which have taken place in the metal market in the course of the last week are all in favour of sellers. The latter manifest no disposition to press sales, so that buyers have in many instances found themselves compelled to offer higher prices. The situation is, however, largely artificial, being in the main the outcome of speculative operations. Copper has further advanced. Tin has followed the upward movement. Lead is quiet at last week's prices. Spelter, though not in strong demand, remains very firm, with a tendency to rise.

TEXTILE MANUFACTURES.—The situation of the textile goods trade is on the whole unsatisfactory, and without prospect of speedy improvement. The spinning industry is beginning to feel severely the effects of the depression. The shoddy spinners have reduced production to one-half by working half-time. The "vigogne" spinners of Saxony have under consideration a proposal to greatly restrict production. The worsted spinners, who have already considerably reduced their output, are about to make a further restriction. They only wait a similar movement on the part of their French rivals.

THE FLOATING EXHIBITION.—The German Industrial Floating Exhibition—that is, the scheme for sending a vessel laden with samples of German manufactures round the world—seems to be regarded with growing favour. The number of exhibitors already reaches 500. Some of the principal firms of South Germany and Silesia have within the last few days applied for space.

NEW GLOW LAMP FILAMENT.—The Allgemeine Elektricitäts-Gesellschaft has just introduced a new glow lamp filament, made from cellulose, which is said to give excellent results economically.

VIENNA, 23rd June, 1890.

THE IRON MARKET.—The Austro-Hungarian iron syndicate will come to an end with the present year, but most of the firms connected with it are agreeable to its continuance for another three years. Although the official resolution to this end cannot be passed until the autumn, the prolongation of the syndicate can already be considered secured. Manufacturers say that the continuance of the agreement will contribute to the maintenance of the excellent condition of the market, and that there is no cause to decrease the prices. The present situation is very firm, and there is a good prospect for the future. Last week the Nadrager Eisen-Industrie-Gesellschaft held its general meeting. The total business last year of this company amounted to 524,000fl., and increased 24 per cent. on that of the previous year. The company made a profit of 103,000fl., and a dividend of 5 per cent. will be paid. The Vienna tool manufactory, Reinhard Fernau & Co., has bought the works of the bankrupt waggon manufactory of C. von Milde & Co., for the price of 210,000fl.

THE COAL MARKET.—In the coal market there is still great animation. Prices continue very firm, and colliery owners decline to make contracts for the winter season at the current rates. In the Bohemian market a want has been felt for high-class coals since the inundation of the pits at Osseg. The Brüxer-Kohlenbergbau-Gesellschaft are making efforts to strike new seams, and last week one was obtained at a depth of 332 metres. According to a circular issued by the directors of the Salgo-Tarjan collieries, this company is paying back 20fl. of the capital to each share. The company did an extremely good business last year.

BRUSSELS, 24th June, 1890.

IRON.—The market for iron is still greatly depressed, and the depression affects equally all branches of the trade. Generally speaking, the rolling mills work only four days a week. The recent reduction in prices has had but little effect in stimulating the market, buyers being encouraged to persist in their policy of abstention by the declining tendency of the German and French markets. The general aspect of the industry is gloomy. There has been some inquiry for joists on English account, but the prices offered were too low to be accepted except in the case of a few small lots. The production of pig iron is being more and more restricted, yet stocks continue to accumulate. Prices are merely nominal, there being practically no business doing. The English plate-makers are now underselling the Belgian manufacturers in the foreign markets.

COAL.—The persistence with which the colliery owners maintain their prices is due largely to the fact that the French demand is exceptionally heavy. Coal is still scarce in France, and a great rise of prices, joined to a notable reduction of the output from the mines of the Saar district, has opened up a new market for Belgian coal in the direction of the Vosges. The near prospects of the great coal-consuming industries of this country, particularly the iron industry, are therefore discouraging from this point of view. But pressure is being brought to bear from the German side. German coke is now being offered to French consumers at 14s. a ton at the pits. In consequence of this the Belgian Coke Syndicate has reduced its prices from 20s. to 16s. a ton. Coal prices remain unaltered. The production of coke has been reduced fully 20 per cent. in the last few weeks. The statistics of coal mining in the Mons district, in which 28,160 hands are employed in nineteen mines, show the average wages for all hands, above and below ground, in the year 1889, to have been 2·87fr. a day, against 2·64fr. in 1888. The present rate is considerably above the average for last year.

GLASS.—The market for glass continues lifeless. Recent reductions in prices seem to have checked the already slack current of business by inducing buyers to wait for further reductions. Of course, in these circumstances the state of the industry grows worse every day, for while the selling prices decline the cost of production rises in consequence of the smaller output. Several of the larger works are now on half-time. The export trade to the United States has been moderately active in the last two or three weeks.

DÜSSELDORF, 24th June, 1890.

IRON.—The iron market becomes week by week more and more depressed. The recent reductions in the prices of pig have so far had no appreciable effect in stimulating business. The fact of large quantities of foreign pig being thrown on the market has neutralised the effect of these reductions. Consumers perceive that they have nothing to lose by waiting, and continue to buy only for present needs. Spiegel pig of the 10 to 12 per cent. quality may now be bought for 90s. Business is very languid in the market for finished iron and steel. Buyers hold aloof, waiting for the reduction in prices which must necessarily follow that lately made in crude iron. The declining prices of coal favour the expectation of a large drop in finished iron. The only class of iron now being dealt in is joists, for which the builders have to press for prompt delivery. The tone of affairs generally is gloomy. Reports from Upper Silesia are less favourable.

COAL.—Interest continues to be centred in the coal market. For the moment prices are maintained with some firmness; but the fact that the daily output of the pits in this district is still kept up to some 95,000 tons, in spite of the slack demand, points to a further decline. The coke syndicate has announced a reduction of 10 per cent. in prices. Sales of coke to French consumers have been made at 14s. a ton at the ovens. The merchants are offering both coal and coke at prices that are considerably below those fixed by the syndicate. Hence consumers are encouraged to hope for easier terms later in the season.

THE CLOTH TRADE.—The Cloth Manufacturers' Association of Aix-la-Chapelle and Burtscheid have decided to hold annually two cloth auction sales at the former town, the first to take place in November next.

THE GLASS TRADE.—The Association of German Plate Glass Makers, with a view to check to constantly increasing imports of window glass, have decided to adopt measures for controlling the whole of the production of the German works, and thereby render competition less difficult.

THE GUNPOWDER TRADE.—The balance-sheet of the United Rhenish-Westphalia Gunpowder Company for the second half of the year 1889 has just been issued to the shareholders. We learn from it that the net profits for the half-year amounted to 430,598 marks (£21,529), a clear 6 per cent. on the share capital. This makes 12 per cent. for the year. It appears that the export trade of the company is steadily increasing.

LILLE, 24th June, 1890.

IRON.—Our manufacturers seem unable to hold their ground any longer, for not only have the official prices—that is, the syndicate minimum—been reduced, but, under the name of discounts, commissions, &c., the minimum is being undersold. So irregular has the market become that it is impossible to say what the current prices are. These concessions have, as usual, driven buyers out of the market, for their effect is to weaken confidence in the situation. There is never much buying in a falling market. The fresh orders now coming to hand are scarcely sufficient to absorb one-half of the production.

TEXTILE MANUFACTURES.—The last week has been a quiet period for the linen goods trade. The amount of business transacted fell below the average, and compares unfavourably with that of the corresponding week of last year. In the matter of prices the market is steady. The latest report of the woollen goods trade at Roubaix, just to hand, is written in a despondent tone. Business is greatly depressed, and the prospect has no encouraging feature. There is very little doing in the market for raw wool. A correspondent, writing from Calais, says that the prospects of the tulle industry are improving. At least the manufacturers appear to have some grounds for expecting a fairly active autumn business.

FLAX AND YARNS.—The demand for home-grown flax continues active and prices are constantly rising. A fairly brisk business is being done in Russians; the demand is, however, scarcely so strong as it was a week ago. Tows of good quality are inquired for, prices being in favour of buyers. There is an active market for yarns, the prices for which still tend in favour of the spinners, who manifest no eagerness to sell. Jute yarns are in strong demand at full prices.

AMSTERDAM, 23rd June, 1890.

RAILWAYS.—The Second Chamber of the States-General has approved, by only a small majority, the Government measure for the acquisition of the Dutch-Rhenish Railway and the division of the working of the State Railways between the Holland Railway Company and the State Railways Company. The Bill now goes to the First Chamber, and, as the majority there is not in favour of the present Ministry, fears are expressed that the Government proposals may not be sanctioned after all, the voting upon them having been of such a narrow character in the Lower Chamber. Hence, the shares of the Dutch-Rhenish Railway Company have not risen to the value which they would represent if paid off in accordance with the pending Bill.

THE AMSTERDAM EXHIBITION.—The International Exhibition in Amsterdam of appliances for minimising danger to life and limbs of workmen in factories and workshops has been opened with much ceremony, and proves a great success, the daily average attendance of

Digitized by Google

visitors being over 1,000. In connection with this interesting Exhibition a special journal is issued, which will continue to be published whilst the show lasts.

THE ELECTRIC LIGHT IN AMSTERDAM.—The Communal Council in Amsterdam is now discussing the proposal for granting an exclusive concession for the electric lighting of the city during a term of years. The city will share in the profits made, but the proportion is not yet fixed. The town authorities of Rotterdam have also introduced a similar Bill into their own Council for the lighting of Rotterdam.

THE NEW LINE OF STEAMERS TO MEXICO.—The Dutch Consul-General in Mexico has reported to the Government that the improvements of Tampico Harbour have been commenced by the removal of the sandbank barring the mouth of the Panuco river. It is expected that this important work will be completed early next year, when there will be 24ft. of water in Tampico Harbour. In connection herewith, and with the recent opening of the railway from Tampico to San Louis Potosi, the Dutch Consul-General again urges the prompt necessity of establishing a new and direct line of steamers from a Dutch harbour to Tampico. A Dutch syndicate has now been formed in Amsterdam for the promotion of this scheme, and the Mexican Government has been requested to grant a preliminary concession.

COPENHAGEN, 21st June, 1890.

THE TIMBER INDUSTRY IN SWEDEN.—Of late a good many new saw mills have been erected in Sweden, and several of the older establishments have been extended and had new machinery installed. Jonsson & Co. have built a saw mill at Ockelbo, with planing machinery, &c. The engine is from Bolinder's, Stockholm; the saw mill from Sjoström, Gefle; and the planing machine from Beronins's firm, Eskilstuna. Electric lighting has been installed. At Iarfed a new extensive saw mill is in course of construction, as is also one at Okue. The latter is being built by the Okue Augsagsbolag. The new saw mill at Munksund commenced work about a month ago, and the new saw mill at Boxholm, which was built in lieu of the one destroyed by fire, has also been going for some time. The latter is rather a large establishment, and the machinery has been supplied by Bolinder's Engineering Works, Stockholm. Altogether these many new saw mills have furnished a lot of work for the manufacturing engineers in Sweden, especially in connection with the numerous wood pulp manufactories which have been erected. The floating down of timber proceeds satisfactorily. At Tägtens bar, Dalälfven, 625,000 timbers had been taken out up to the middle of June, and about 750,000 timbers were then remaining. At Nye Kelby, 572,500, and at Tovstong, 510,500 timbers had been taken out. In several districts of the Vösterdal river the floating is still in full progress.

GAS WORKS IN SWEDEN.—According to the latest official statistics, there are in Sweden twenty-six gas works, with an annual production of 694,357,425 cubic feet of gas. The largest gas works are those in Stockholm, Gothenburg, and Malmö, and the smallest the one at Södertelze, with an annual production of only 784,000 cubic feet. There are twenty-two coke manufactories, with a production of 3,216,511 cubic feet of coke.

RAILWAYS IN NORWAY.—The Norwegian Government proposed some time ago to build several new railway lines. This measure has now been considered in a special committee, who have altogether reported favourably on the matter. The question has not yet been before the Storthing, but there is every probability of the various proposals being passed. The question about the important Bergen line will, to all appearances, be allowed to remain in abeyance for some time yet, much to the disappointment of the large districts interested in the construction of such a railway.

THE SWEDISH-NORWEGIAN RAILWAY COMPANY.—There do not appear to be any immediate prospects of the transfer to the Swedish State of this company's Lulea-Gellivara section. There have lately been several representatives for the Dutch debenture-holders in Stockholm, in order to confer with the Swedish Government about an agreement, but no result was arrived at. The parties were agreed about the cash payment offered by Sweden, but the debenture-holders seemed loth to part with their entire rights. Besides, they have not yet the full legal power to dispose of the railway, which is, of course, a *sine qui non* condition for an eventual transfer. The matter was left open at present, so that the debenture-holders might try and get this point arranged. As far as the Norwegian section of the railway goes complete uncertainty still seems to prevail. The Norwegians are not satisfied with the present state of affairs, and think the Swedish Government has favoured the company at the expense of the Norwegian interests. The original terms of the concession stipulated for the same length of railway being built every year on the Norwegian and on the Swedish sections. This was afterwards altered, so that the same sum should be expended on each section every year, the building in Norway being more expensive than in Sweden. This was afterwards again altered in this manner—that there should be half the money expended in Norway of what they were building for in Sweden. It almost looks as if there was, at least at present, little or no chance of the Norwegian section being taken in hand again.

MADRID, 23rd June, 1890.

CUBA RAILWAYS.—After many weeks of keeping this question open, the Government has at last decided not to give the concession to either of the two tendering parties. The outside view of the question is that the English proposals required some changes, though very likely the tendering parties would have agreed to accept the concession on the precise terms of the Government. But some very influential politicians were in favour of the rival tender, and rather than see the concession given to the English company, made a point of its not being given to either.

GOLD MINING IN SPAIN.—Every now and then the question of gold mining is revived. There are at present three interesting workings. In the first place there is the Guadalajara mines, which are now in the hands of an English firm. Next to this a Mr. Brown is doing some work at the old mine of the Oriental Company in the province of Toledo. This mine has always been one likely to succeed if plenty of capital were employed. Lastly, a wonderful gold mine is reported to have been discovered in the North. The work will be commenced early next month, when some report of the actual results may be obtained.

THE SPANISH PATENTS LAW.—By the Spanish patent law a patent is void if not practised within two years of its being granted. In ordinary cases some means are found to prove that an invention relative to a machine has been applied; for instance, the parts of a machine can easily be made and applied even in one case only, and then a certificate may be obtained. There are some patents, however, in which that way of proving the practice is impossible. It is noteworthy that a number of very valuable patents are now void in this country on account of their not having been applied within two years. Any one could now obtain five years' patents for these processes, and would be entitled to their exclusive use. Then even the inventor himself could not apply his process in Spain.

NEW YORK, 14th June, 1890.

THE IRON AND STEEL MARKET.—The demand in all lines is fair and prices are firmly held, and indications point to better business in the near future. Prices for pig iron are firmer, and full-quoted rates are being insisted upon. This, to large consumers, means an advance of from 25c. to 50c. a ton, and orders are coming in only as the material is needed. Any quantity of iron, at full rates, can be bought for June and July delivery, but beyond that makers are taking few orders, as it looks as though prices would advance after that time. For manufactured iron prices are unchanged, but the market is firm and confident. The demand for all sorts of finished iron and steel is improving, and prospects indicate a large business during the next three or four months. The mills are already beginning to feel the effects of the improvement. Best refined bars are quoted at 1·80c. to 1·85c. per lb., plates at 2·10c. to 2·20c., and angles at 2·20c. to 2·25c. Large sales of skelp iron were recently effected at 1·75c. per lb. delivered, but sellers now take 1·75c. to 1·80c. on all new business. The demand for steel rails is improving, and prices are firm at an advance of half a dollar per ton, so that $32 is the inside price for large lots. Billets are showing great strength, and prices have risen a dollar per ton in the past week. The demand has largely increased, so that prices are likely to go higher. Mills are all running to their full capacity.

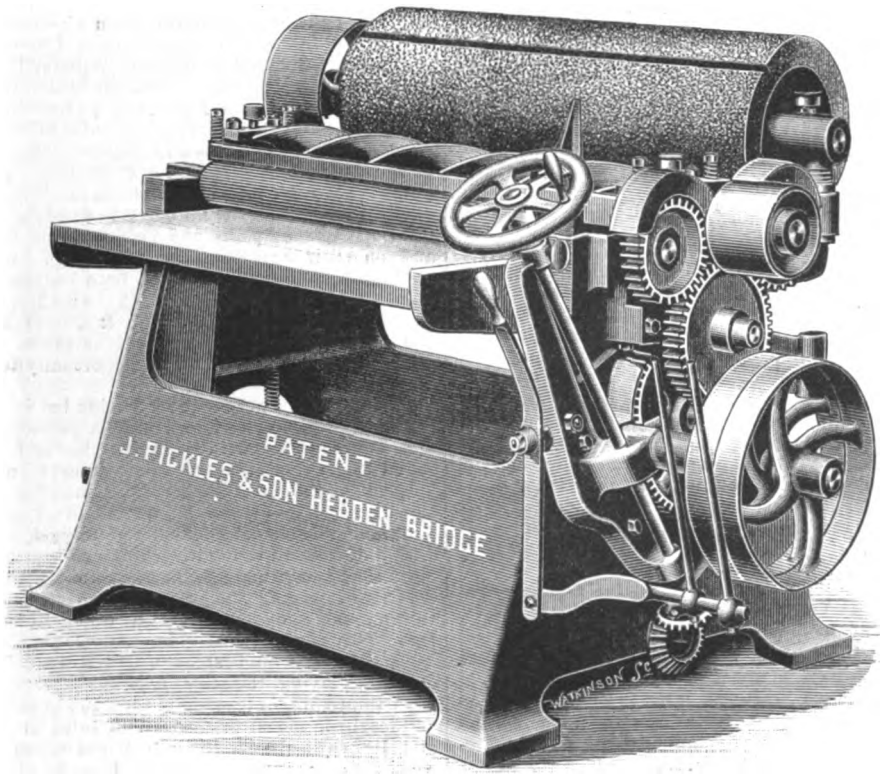
SHORTENING TRANSATLANTIC TRIPS.—At a meeting of the Land Board of New York State on the 10th, an application was received from the New York and Long Island Railroad Company for a grant of the right of way, 99ft. in width, and 50ft. in height, under the bed of the East River, within which to construct a tunnel for the use and operation of its railroad. The tunnel will begin at Tenth Avenue and Forty-second Street, in New York City, and run easterly under Forty-second Street and the East River, coming to the surface at Hunter's Point, Long Island City. If no remonstrances are filed the Commissioners will grant the application at their next meeting. It was current during the last session of the Legislature, that the Ramey Bill to bridge the East River to Long Island City was backed by Mr. Austin Corbin, the President of the Reading Railroad. He said that as soon as he got the bridge over the East River he would double-track the Long Island Railroad, which begins at Long Island City and runs to the eastern, or Montauk, end of the island. The object of the scheme was to establish a line of steamers between Montauk Point and Liverpool, and give the best of rapid transit from the Point to New York City, thus shortening the ocean trips over a day. Some time ago when Montauk Point was sold by auction, it was bought for Mr. Corbin for $275,000. The Bridge Bill failed because of the refusal of the Governor to approve it, and it is now the intention to accomplish by means of a tunnel what they wished to accomplish by the bridge.

THE NEW NAVY.—Bids for over five million dollars' worth of new naval vessels were opened at the Navy Department on the 10th inst. The largest of the three vessels, which is the largest ever designed for the United States Navy, is known as "Armoured Cruiser No. 2," and is of 8,100 tons. She will carry light armour and a 6in. protective deck. She will be armed with six 8in. and twelve 4in. breechloading rifles. The engines are to develop 16,000 h.p., and to drive the ship at 20 knots. Her principal dimensions are—Length, 380ft.; extreme breadth, 64ft. 2½in.; and depth of hold, 41ft. 3in. The other large vessel is designated as "Cruiser No. 6," and is to have a displacement of 5,500 tons. She has no armour, but is provided with a protective deck 4½in. thick. Her main batteries consist of two 8in. and ten 4in. breechloading rifles. The vessel is of the same type as, but of heavier tonnage than, the "Baltimore," "Philadelphia," "Newark," and "San Francisco." Her dimensions are—Length, 330ft.; extreme breadth, 53ft.; and depth, 33ft. The third vessel is the practice cruiser of 800 tons, a miniature man-of-war for the training of the cadets at the Naval Academy. The appropriation limits for the three vessels are as follow:—Armoured cruiser, $3,500,000; protected cruiser, $1,800,000; and $260,000 for the practice ship. For the armoured cruiser on the plans and specifications of the Navy Department the Union Iron Works, of San Francisco, bid $3,100,000; William Cramp & Sons, of Philadelphia, $3,150,000; and the Risdon Iron and Locomotive Works, of San Francisco, $3,450,000. The Union Iron Works and the Cramps also submitted bids for this vessel on their own plans and specifications, the former for $3,000,000, and the latter for $2,985,000. The only bids for the protective cruiser were from the Union Iron Works, of San Francisco. They propose to construct the vessel on the Department's plans and specifications for $1,796,000, and on their own plans for $1,760,000. Two bids were received for the practice vessel, both on the Department's plans—F. W. Wheeler, of West Bay City, Michigan, at $245,000, and Samuel L. Moore & Co., of Elizabethport, N.J., at $250,000. No award will be made until the Department officers have had an opportunity to examine the bidders' proposals.

BRICK PAVEMENTS.—Brick paving has been thoroughly tested in Galesburg, Illinois, and is pronounced a success after six years' trial with about five miles laid. Three manufactories there now make paving brick, turning out about 160,000 daily and employing 400 men. The clay is exceptionally good, and is ground up and sifted as fine as flour, and then moistened, moulded, and burned in a close kiln with a downward draught. From one-fourth to one-third more time is consumed in burning than with the ordinary brick. In burning the brick shrinks from 9in. in length to 8in., and proportionately in other directions. It is thoroughly vitrified throughout and weighs about 5lb. This brick will resist the best steel drill and a chip will scratch glass. In laying, the street is properly graded and covered with 4in. to 5in. of macadam, then 4in. of sand is put down and levelled. Then one course of brick is laid down flat and lengthwise with the street and rolled with a light roller; on this course is placed 1in. of sand, and then a final course of brick is laid on edge and across the street; a ¼in. of sand on top fills the crevices, and the whole is well rolled. The street is graded with a fall of 6in. in 19ft. from the centre. The fall is carried to within 3ft. of the curb, where it is level to within 1ft. of the curb, and then rises 1in. This pavement has stood the test of the severest traffic of the town, in some cases for six years; it shows no wear, and has cost literally nothing for repairs. As to price, the contractors were required to do the grading, furnish sand and all other materials, except only the guttering, and make the pavement complete, and all this they did for $1·40 per yard. The paving bricks sell at Galesburg for $8·50 per 1,000 on cars, and the price is shaded to $8·25 per 1,000 on large contracts.

PHILADELPHIA, 13th June, 1890.

NEW RAILROAD CARS.—The rivalry between the Pennsylvania Railroad and the Baltimore and Ohio-Reading-New Jersey Central combination in the lines between New York and Washington has led the latter to determine to do away with all the old cars on the New York line, and replace them with new ones. The line will be known as the Royal Blue Line, from the colour of the cars. The three companies have ordered the cars from the Pullman Company, of Chicago. There will be sixteen passenger coaches, eight combination cars for baggage and passengers, and ten parlour cars. Each train will consist of four or five cars. Each car will be vestibuled, and will have a smoking apartment for twelve persons. The cars will be lighted with gas and heated with steam, and will have automatic brakes. There will be no extra charge for travel in these trains, except for seats in parlour cars and berths in Pullman sleepers. The expense of equipment is to be borne equally by the three companies.



THE NICARAGUA CANAL.—The first dredger for the Nicaragua Canal sailed from Charleston, South Carolina, on the 28th ult. Three others will follow within forty days. These are all for the harbour dredging work, and not for the main channel of the canal, the dredging for which cannot be economically pushed till work on the great divide cut is well advanced. The railway to reach the latter, for which Mr. Chas. P. Treat has the contract, is being pushed as fast as possible, and is likely to be finished early in the autumn.

THE MARYLAND AND DELAWARE CANAL.—The Maryland and Delaware ship canal project is again revived, and there is talk of an early commencement of work. The enterprise is said to be in the hands of a French company, with $8,000,000 capital. The route selected is the Sassafras route, surveyed in 1874. It will begin at Sassafras, on Chesapeake Bay, 39½ miles from Baltimore; then up that stream 16½ miles; then through a country with 80ft. maximum cutting above low water, and down the valley of the Black Bird Creek. It finally passes through a ridge of high ground, and enters Delaware Bay near Liston's Point. The solid cutting is only 7½ miles, and the whole distance between navigable water on both sides is but 14½ miles.

PLANING, THICKNESSING, AND GLASS PAPERING MACHINE.

CONSTRUCTED BY MESSRS. JOHN PICKLES & SON, HEBDEN BRIDGE, YORKSHIRE.

DUTTON'S SIGNAL LAMPS.

WE illustrate herewith in Figs. 1, 2, 3, 4, 5, and 6, Dutton's improved signal lamps. The particular features of novelty in these lamps are the form of the lens used and the method of cutting a part away so as to show a difference between the lamps used for distant, shunt, and home signals. The lamps can be used either with gas or oil, and are so made as to allow the gas fitting to be turned down on an elbow joint out of the way when the oil lamp is in use. In Figs. 1, 2, and 3 the lens A is circular with a segment cut off the top and bottom. The inner face is flat, and the central part of the outer face is convex and surrounded by raised zones in which the radii of convexity increase as they are more remote from the centre of the lens. This is shown clearly in Fig. 2, where the effect of the shape of the lens and of the parabolic reflector is to cause the rays to diverge laterally more than usual, but to show a well-defined disc of light in the centre. Fig. 1 shows the oil lamp in use with the gas tube B turned down out of the way; the air enters as shown by the arrows. Fig. 3 shows the oil lamp removed and the fitting for the gas jet placed inside the case. Fig. 2 is a sectional plan of the lamp. The lens is often made circular, and exhibits a brilliant light visible from any point of observation within a lateral range of 60°, which is a considerable improvement upon the narrow field of effective light given by the ordinary lamps in use. In order to clearly distinguish the home, starting, and distant signals at night the lens is cut away in the centre and a black plate is inserted, as shown in Figs. 5 and 6, the distant signal lamp having a taper horizontal bar, and the shunt-signal lamp a vertical parallel bar across it. As the lens is made of colourless glass, when the signal arm hangs at "all right" a white light is seen with a dark bar across it, and when the signal arm stands at "danger" the red spectacle glass comes down in front of the lamp and so causes a red light to be shown crossed with a dark bar. These lamps are now in use upon several of the main lines in England, Scotland, and Ireland, and are manufactured by Messrs. Dutton & Co., Limited, of Worcester.

PLANING, THICKNESSING, AND GLASS PAPERING MACHINE.

THE accompanying illustration represents an improved machine for planing and glass papering timber, made by Messrs. John Pickles & Son, saw mill engineers, Hebden Bridge. It is fitted with spiral cutters, for it is a well-known fact that, while planing and thicknessing machines with straight cutters are found very useful for working soft and common woods, they are found deficient when used for hard and gnarly, or cross-grained timber, and require an extra amount of hand labour being expended upon the object to get up the necessary face and finish. To obviate and remedy the above defects various means have been adopted. The spiral cutter meets the difficulty, and renders the planing of most curly timber, parquetry, or other difficult work quite an easy and inexpensive process. The cutter gently enters the timber under operation, and takes off a very fine shaving, and when the blade has worked for about 7½in. in width, another blade commences cutting, so that with a 30in. cutter, all the blades are working at the same time. For grinding the cutters from time to time, a special grinding apparatus has been devised which can be readily fixed by two bolts upon the table of the machine. This grinding arrangement consists of a fine emery wheel fixed upon a sliding arm. This enables the cutter to be presented in its entire length to the emery wheel. The feeding of the timber through the machine is affected by means of four rollers, two on each side of the cutters, the top rollers being driven, the front one being grooved. These rollers are fitted with an efficient variable spring pressure arrangement. Between the feeding rollers and the cutter spindle are provided pressure bars, with spring arrangement, to keep the timber under operation firmly down upon the bed of the machine. The bed or table is provided with lips which obviate the indenting of the timber a short distance from the end. The table is raised or lowered by means of a hand wheel, and bevel and screw motion on each side of the machine, to suit the different sizes of timber to be operated upon; an index and pointer being arranged which shows at a glance the measurement of the object passing through. The illustration clearly shows the glass papering roller, which is placed at the upper part of the machine facing the operator. The main frame of the machine is all cast in one piece, and is very strong and self-contained, and does not require any special foundation.

SHIPBUILDING NOTES.

ON the 5th inst. the screw steamer "Zampa," recently completed by Messrs. Edward Withy & Co., Middleton Shipyard, Hartlepool, proceeded on her trial trip in Hartlepool Bay. This vessel is an excellent type of a modern cargo steamer, and has been built for the fleet of Messrs. Herskind & Woods, West Hartlepool. The steamer is over 300ft. in length, and is built throughout of Siemens-Martin steel. She has a long raised quarter-deck, short poop, long bridge-house, and topgallant forecastle. The holds and 'tween decks are fitted throughout with iron grain divisions. She is built on the web-frame system to give extra strength and to enable the vessel to stow cargoes of the bulkiest description. She has large water ballast capacity fitted all fore and aft. To facilitate the discharging of cargo she is fitted with four large steam winches and a large donkey boiler. The triple-expansion engines and boilers have been supplied by Messrs. T. Richardson & Sons, Middleton Ironworks, Hartlepool.

ON the 12th inst. the s.s. "Tandil" proceeded from the Tees on her trial trip. This vessel has been built for Messrs. Arthur Holland & Co., London, by Messrs. Raylton Dixon & Co., Middlesbrough. She is built on the web-frame principle, having a poop, raised quarter-deck, bridge, and topgallant forecastle. Her leading dimensions are:—Length over all, 287ft.; breadth, 39ft.; depth, moulded, 21ft. 3in.; and dead-weight capacity about 3,300 tons.

Digitized by Google

Her engines have been fitted by the North-Eastern Marine Engineering Company, Limited, Sunderland, and on trial gave every satisfaction, developing a speed of 11 knots.

ON the 17th inst. Messrs. D. & W. Henderson & Co. launched, from their yard at Meadowside, Partick, four steel schooners, named respectively "Mosquito," "Avis," "La Honmiga," and "Arana." The schooners have been built to the order of Messrs. J. & A. Allan, of the Allan Line, and are intended for service on the River Plate.

ON the 17th inst. the s.s. "Strathavon," 2,500 tons, was launched from the yard of Messrs. Russell & Co., Greenock. The vessel will be supplied with triple-expansion engines by Messrs. Blackwood & Gordon, Port Glasgow. The dimensions of the vessel are:—Length, 306ft.; breadth, 41ft.; and depth, 22ft. 2in. The owners are Messrs. Birrell & Sons, Glasgow.

ON the 18th inst. Messrs. Raylton Dixon & Co. launched from their dockyard at Middlesbrough a steel screw steamer, which has been built to the order of Messrs. Arthur Holland & Co., London. She is built on the web-frame principle, having poop, raised quarter-deck, long bridge, and topgallant forecastle. She is of the following dimensions:—Length over all, 287ft.; breadth, 39ft.; depth, moulded, 21ft. 3in.; and dead-weight capacity about 3,300 tons. Her engines will be fitted by the North-Eastern Marine Engineering Company, Limited, Sunderland, and are to have cylinders 21in., 35in., and 57in. diameter, by 39in. stroke. On leaving the ways the vessel was christened "Alfalfa."

ON the 18th inst. Messrs. Richardson, Duck, & Co. launched from their yard at South Stockton a steel screw steamer of the following dimensions:—Length over all, 307ft. 4in.; breadth, extreme, 40ft.; depth of hold, 20ft. 2in.; and dead-weight carrying, about 365 tons. The vessel has a half poop aft; accommodation for captain, officers, and passengers amidships; a raised quarter-deck, and a long bridge from after engine-room bulkhead to stem. The engineers are berthed in a deck-house on the quarter-deck abaft the engine casing, and the crew in forecastle. She has a double bottom all fore and aft, on the cellular principle, capable of containing about 560 tons water ballast. She is fitted with an Emerson-Walker's patent steam windlass, four horizontal steam winches, &c. The engines have been supplied by Messrs. Blair & Co., Limited, and their cylinders are 22½in., 37in., and 61in. diameter, by 42in. stroke.

ON the 19th inst. Messrs. Ropner & Son launched from their shipyard at Stockton one of the largest vessels that has ever been built on the Tees. Her dimensions are:—Length over all, 378ft. 6in.; breadth, extreme, 47ft.; depth, moulded, 29ft. 9in.; and dead-weight, 6,300 tons. She is built of Siemens-Martin steel. She has full poop, long bridge-house, and T.G. forecastle and cellular bottom for water ballast. Her engines are by Messrs. Blair & Co., Limited, of 2,100 i.h.p., which will give a speed of over 10 knots laden. She will be fitted with direct steam windlass, Davis's steering engine placed abaft the engine skylight, with shafting connecting it to the main and upper bridges, six very large steam winches, horizontal multitubular donkey boiler, double derricks, and all the latest appliances for the quick loading and discharging of cargoes. The steamer has been built to the order of Mr. Christopher Furness, of West Hartlepool, and as she left the ways was christened "Pakeha."

ON the 19th inst. the clipper-stem spar-decked screw steamer "Prodano," built at Blyth, by the Blyth Shipbuilding Company, Limited, for Messrs. Pinkney & Sons' Steamship Company, Limited, of Sunderland, had a highly satisfactory trial trip. An average speed of 11¾ knots was steadily maintained. The North-Eastern Engineering Company, Limited, of Sunderland, supplied the engines.

ON the 19th inst. the s.s. "Duckenfield," recently launched by Messrs. Fleming & Ferguson, shipbuilders and engineers, Paisley, went down the river for her speed trial. On the measured mile she attained a mean speed of 11¼ knots. The "Duckenfield" is a steel twin-screw steamer, and is fitted with overlapping propellers. Her dimensions are:—Length, 220ft.; breadth, 31ft.; and depth, 15ft. 6in. The engines are of Messrs. Fleming & Ferguson's patent quadruple type, and indicate 1,200 h.p. with 200lb. steam pressure. This vessel has been built to the order of Messrs. J. & A. Brown, of Sydney, for their Colonial trade.

ON the 19th inst. there was launched from the shipbuilding yard of Messrs. D. & W. Henderson & Co., Glasgow, a steel screw steamer named the "Scindia." The dimensions of the vessel are:—Length, 375ft.; breadth, 46ft.; depth, 30ft.; and gross tonnage, about 4,300 tons. The "Scindia" is intended for Messrs. Henderson Brothers' Eastern trade. She is to be fitted with a complete installation of electric light, and a search light for night passage through the Suez Canal. She will also be fitted with patent steam steering gear by Messrs Napier Brothers, and steam windlass by Messrs. Harfield & Co. The builders are to supply triple-expansion engines, having cylinders 26¾in., 44in., and 72in. diameter, by 60in. stroke. She will be rigged as a two-masted schooner with square sails on foremast.

ON the 19th inst. the "Jose Romane," a screw steamer, was launched by the Grangemouth Dockyard Company. The dimensions of the vessel are:—Length, 170ft.; breadth, 25ft.; and depth, 11½ft. The vessel has been specially built for the Mexican passenger trade, and is to be supplied with triple-expansion engines by Messrs. Hutson & Corbett, Kelvinhaugh.

ON the 21st inst. the "Templemore," a three-masted steel sailing ship, was launched by Messrs. Russell & Co., Port Glasgow. The vessel has been built to the order of Messrs. Thomson, Dickie, & Co., Glasgow. Her dimensions are:—Length, 260ft.; breadth, 38ft.; depth, 23ft.; net register, 1,700 tons.

ON the 21st inst. the trial trip of the s.s. "Norna" took place in Hartlepool Bay. She has been constructed by Messrs. Edward Withy & Co., Hartlepool, for Messrs. Herskind & Woods, of West Hartlepool. Her engines are of the triple-expansion type, with cylinders 21½in., 35in., and 58in., by 39in. stroke, and have been built at the Central Marine Engine Works, West Hartlepool. During two hours' consecutive steaming a mean speed of 11 knots was obtained.

ON the 23rd inst. there was launched from the yard of Messrs. S. McKnight & Co., Ayr, the "Garnock," a screw steamer of the following dimensions:—Length, 160ft.; breadth, 25ft.; depth of hold, 12ft.; and dead-weight capacity, 560 tons. The engines will be of the triple-expansion type, with cylinders 14in., 22½in. diam., and 36in., by 27in stroke. The "Garnock" has been built to the order of the Garnock Steamship Company.

ON the 23rd inst. the "Glenbreck," a four-masted steel sailing ship of 1,930 tons gross, to carry 3,100 tons cargo, was launched by Messrs. Robert Duncan & Co., Port Glasgow. The "Glenbreck" has been built to the order of Mr. Robert R. Paterson, Greenock. Her dimensions are:—Length, 270ft.; breadth, 40ft.; depth, 23ft. 8in.

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER: We have to report a strong market in copper, with large trade at advancing rates. During the greater part of the past week there has been a quiet market for raw, owing to slackening off in buying, but a large business is again taking place, and the market is firmer. The decreased stocks and increased demand caused by new outlets for consumption will tend to strengthen the market and maintain prices. Chili bar quotations to-day are £58 17s. 6d. to £59 5s. cash, and manufactured £72 sheets, £75 bottoms.

TIN has been dull and inactive throughout the week, and values have declined. To-day's market, however, is firmer, at improving rates.

LEAD steady, but with small business doing. Values are practically unchanged.

SPELTER continues firm, with small business doing. The market is, however, bare of stocks, and buyers have to pay full prices.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

CHEMICALS: Caustic soda has had a firm market during the week, and has advanced a little. Bleaching powder, after declining somewhat, has recovered, and closes firmer. Soda ash is more plentiful at slightly lower prices. All transactions in these goods are, however, for early delivery, makers declining to sell far forward. Sulphate of copper is more freely offered for July delivery at considerably reduced prices. Acetates of lime are drooping. Acetates of lead and nitrate of lead are steady, with moderate inquiry. Recovered sulphur in demand.

LAMPS.—Messrs. James Guthrie & Co., 9, Leather Lane, Holborn, E.C., have sent in a well-illustrated catalogue of the lamps for household use manufactured by them.

MESSRS. HETHERINGTON'S TOOLS.—We have received a magnificently illustrated catalogue of machine tools manufactured by Messrs. Hetherington & Co., Ancoats Works, Pollard Street, Manchester. Perhaps the best way to describe the style of this catalogue is to say that it is only equalled by the excellent workmanship for which this firm is so well known.

HOME INDUSTRIES.

LONDON, 26th June, 1890.

THE MONEY MARKET.—Money has been growing increasingly dearer, and now it has reached very stiff figures. The approach of the end of the half-year always produces a strong demand for money, and the situation is complicated this week by the incidence of a Settlement and by the generally unfavourable nature of the monetary position. Gold continues to flow to the Continent. The maintenance of harder rates for loans and discounts seems inevitable for some considerable time. The stock markets have been quiet and dull in consequence of the Settlement. Sales to liquidate accounts open for the rise, so as to save the heavier carrying-over rates, were plentifully made at the beginning of the week, and though an occasional feeble rally set in, prices tended generally downwards. An attempt to support Brighton Deferred was not a conspicuous success, and the home railway list has not been strong. Americans have moved within restricted limits just as New York prices were higher or lower than London prices, but no new business has been initiated on this side. Foreigners have stiffened a little after a collapse at the close of last week, but are still far from vigorous. Foreign and Colonial railways are depressed in most cases. Copper mining shares are fairly well supported, but other mines are neglected. Industrial and miscellaneous securities have been inactive, but the most prominent of them have sought a slightly lower level of prices.

COMPANIES.—The following companies have been registered since our last report:—Thomas Ware & Sons, Ld., with a capital of £40,000, to carry on the business of tanners, &c.; The Eccles Spinning Co., Ld., with a capital of £90,000; The Astley Estate Co., Ld., with a capital of £100,000, to acquire collieries, &c., in Lancashire; The Colliery Trust Syndicate, Ld., with a capital of £6,000, to acquire collieries, &c.; Burals' Semi-Metallic Packing Co., Ld., with a capital of £5,000; The Mexican and Central American Railway, Ld., with a capital of £900,000, to construct or acquire railways, &c., in Mexico; The South American Light Railways and Tramways Trust, Ld.; Messrs. James Brierley & Co., Ld., with a capital of £30,000, to acquire lands and erect breweries; Balderstone Mill Co., Ld., with a capital of £20,000, to carry on the business of cotton spinners, &c.; Wellington Mills Co., Huddersfield, with a capital of £400,000, to carry on business as woollen manufacturers; Kent Patent Arc Lamp Co., Ld., with a capital of £10,000; General Phosphate Corporation, Ld., with a capital of £1,000,000, to acquire mines, &c.; British Ballarat Gold Exploration Co., Ld., with a capital of £60,000; Ore Reduction and Smelting Company of South Africa, Ld., with a capital of £50,000; Sir Elkanah Armitage & Sons, Ld., with a capital of £150,000, to carry on the business of cotton spinners, &c.; Birmingham Exhibition Hall, Winter Garden, and County Hotel Co., Ld., with a capital of £50,000; Letaba (Transvaal) Lands Co., Ld., with a capital of £200,000, to acquire lands, mines, &c.; Yew Mill Co., Ld., with a capital of £80,000, to erect a cotton mill, &c.

RAILWAYS.—The gross receipts of the twenty-three principal railways in the United Kingdom for the week ending June 15th amounted, on 16,186¼ miles, to £1,361,933, and for the corresponding period of 1889, on 16,057¼ miles, to £1,391,524, an increase of 129 miles, or 0·8 per cent., and a decrease of £29,591, or 2·1 per cent., the receipts for the corresponding period having included the Whit week traffic.

THE RAILWAYS IN TIME OF WAR.—On Friday afternoon last at the Royal United Service Institution, Whitehall Yard, Mr. George Findlay, Manager of the London and North-Western Railway, and lieutenant-colonel in the Engineer and Railway Volunteer Staff Corps, lectured on the subject of the "Transport of Troops by Railway within the United Kingdom." The view of the lecturer was that, in time of war, when, in accordance with the provisions of the National Defence Act, 1888, the railway companies might be called upon to suspend, as far as might be necessary, the ordinary traffic, in order that the railways might be devoted, in priority, to military purposes, the principal railway officials should become, for the time being, the servants of the State, and the railways should be worked and controlled, under the direction of the headquarters staff, by the officers of the Engineer and Railway Volunteer Staff Corps and the managers of the leading railway companies, that the headquarters staff would instruct them as to the transport required, and they would be responsible for providing it. The lecturer also gave in detail a scheme for working the railways in time of war, and for transporting large armies from one point of England to another.

THE SOCIETY OF ARTS.—The Council of the Society of Arts have awarded the Albert Medal to Mr. W. H. Perkin, Ph.D., F.R.S., "for his discovery of the method of obtaining colouring matter from coal tar, a discovery which led to the establishment of a new and important industry and to the utilisation of large quantities of a previously worthless material." This medal was struck to reward "distinguished merit for promoting arts, manufactures, and commerce," and it is awarded annually.

THE JUNIOR ENGINEERING SOCIETY.—A meeting will be held on the 27th, at the Westminster Palace Hotel, Victoria Street, S.W., at eight o'clock, to consider what steps must be taken in arranging for the summer excursion to the Edinburgh Exhibition. Two visits have also been arranged as follows:—On Thursday evening, the 3rd July, to Messrs. Brin's Oxygen Works, Horseferry Road, Westminster, meeting at the entrance at half-past six; on Friday evening, the 11th July, to the Richmond Gasworks. In connection with the latter, it may be of interest to note that the retorts are charged by West's mechanical stoker, the coal being broken and conveyed to machine by endless belts. The exhaust plant consists of two Galloway boilers and two engines, connected direct to the exhausters. There are eight purifiers, 30ft. by 20ft., capable of acting on 1,000,000 cubic feet per day. Atmospheric air is admitted to assist purification. A new telescopic 3-lift gasholder, 90ft. by 115ft. wide, capacity 750,000 cubic feet, is in course of erection. Total manufacture of gas is 180,000,000 cubic feet per annum. The sulphate of ammonia plant will also be shown.

THE OCCULTING TELEGRAPH.—On Friday, the 20th inst., Major-General H. P. Babbage gave a lecture before the Balloon Society, on the "Occulting Telegraph and its Inventor." The particular object of the lecturer was to claim for his father, the celebrated mathematician, Charles Babbage, the honour of inventing the first practicable occulting telegraph. In 1851 Charles Babbage proposed to number all the lighthouses in the world, giving to each lighthouse its own number, and arranging them so that in the adjacent lighthouses the digits of the numbers should be all different: thus, 271 - 385 - 694 - 781 - 352 - 469 - 827, and so on. The numbers would be indicated by an opaque shade brought down over the flame of the lamp at intervals of one second, with pauses of five seconds between the digits and of ten seconds between each repetition of the complete number. Thus, to represent 271, there would first be two occultations, then a pause of five seconds; followed by seven occultations, then a pause of five seconds; and then one occultation followed by a pause of ten seconds: thus in thirty seconds the lighthouse would have displayed its number, and would keep on repeating it throughout the night. During the Crimean War he also suggested the sending of messages at night by the same principle.

ELECTRIC LIGHTING.—The Metropolitan Electric Supply Company will shortly have their Manchester Square central station in operation. Babcock & Willcox boilers, Willans & Robinson high-speed engines, and Elwell-Parker dynamos will be employed.

MANCHESTER, 26th June, 1890.

THE IRON MARKET.—The rise in pig iron has caused a little more animation in this market, and there is somewhat more doing. Local irons are quoted about 50s. per ton, less 2½ per cent., but hematites are decidedly firm in tone owing to some of the makers having reduced their production. Bar iron is only moderately asked for, and makers are not pressed for delivery, although fairly well off for contracts.

COTTON TRADE WAGES.—The joint conference of manufacturers' and weavers' representatives was held on the 20th inst., and resulted in an agreement being arrived at with reference to a uniform wages list. It is proposed that the new list shall be gradually introduced from the 1st of September next, and be in full operation from the 1st of January, 1891.

THE MANCHESTER SHIP CANAL.—The Bill promoted by the Ship Canal Company empowering them to alter the position, size, and number of the tidal openings in the portion of the canal adjoining the Mersey estuary has been passed by a Select Committee of the House of Commons. The Bill was strongly opposed by the Mersey Dock and Harbour Board, but in spite of this it has been passed practically without alteration.

THE HYGRODEIK.—Under this title a patented instrument for graphically denoting the amount of moisture in the atmosphere of a shed is being introduced by Mr. Chas. Lancaster, of Manchester. The instrument consists of a graduated semi-circular scale, round the face of which the free end of a finger or pointer can travel. The finger is centred near one extremity on a short pin, the other end of which has a small lever or crank fixed on it. To the outer extremity of this one end of a hair is fixed, the other end being securely fastened to a light frame or pillar. As the temperature or humidity in the shed varies the hair expands or contracts, and, as the weight is always arranged to preserve it in tension, the indicator finger is moved across the face of the scale, and readings can be taken at any time as desired.

PREPAYMENT GAS METERS.—A new gas meter, known as the "March Thorp," is being made in considerable numbers by Messrs. Sawer & Purvis, of Manchester. By its aid a pennyworth of gas can be obtained by the consumer. The penny is dropped into a slot and pushed home by a piston or pusher, after which it drops into a locked drawer or receptacle. While the penny is being pushed through it releases a star wheel which is operated by fingers or pawls fixed upon the drum. At the same time a conical valve by which the admission of gas is controlled is raised to a certain height. The revolution of the drum moves this valve down at a speed proportionate to that of the passing gas, and by the time the quantity which can be sold for a penny is delivered the valve closes shutting off the supply. As soon as the gas is supplied the meter drum is again locked by the detention of the star wheel. If while a pennyworth of gas is being consumed the pusher is raised to repeat the action without a coin, no additional supply can be got, and the introduction of another penny insures the valve being opened as much further as is necessary to supply that value of gas, although the remainder of the first portion remains to be delivered. The mechanism is well designed to prevent any fraudulent use being made of it, and is very simple and easily adapted to various requirements.

THE LINEN AND JUTE TRADES.—There has not practically speaking been any change for the better in the condition of the home trade during the week. The wholesale houses are not purchasing, but several buyers are preparing to visit the producing centres both in Scotland and Ireland, and more will be doing shortly. The season has not been at all unsatisfactory, and payments on the part of the drapers have been very good this year. As a result of January–June trading, one of the largest houses in the city will, we are informed, be able to produce accounts which are not marred by a single bad debt—an unusual event where an annual turnover of hundreds of thousands of pounds is concerned. The uncertainty can still be noted in the shipping section, and the future, as far as the American department is concerned, appears gloomy. Very heavy stocks must now exist on the other side, and the increased duties will enable importers to realise large profits on the goods now held by them. Linen threads are quiet and there is not much doing in jute fabrics. The stocktaking is still in progress with many of the houses, but some have completed this semi-annual task. Yarns are quoted at about 1¼d. per bundle lower for certain descriptions of tows, but better qualities are firm.

GLASGOW, 26th June, 1890.

PIG IRON.—There has been a good deal of animation in our market the last few days, and some stir in various brands of makers' iron. Shipments are keeping up well, deliveries ex store continue longer and on a larger scale than had been anticipated, and it is understood that things are not quite so slack in manufactured iron as they were some weeks ago. Warrants advanced steadily to 45s. 9d. cash, but have relapsed since then to a little below 45s., as the impression is gaining ground that a reduction of wages is likely to be brought about without any serious difficulty or interruption of work among the colliers and miners here and in England.

EDINBURGH CALEDONIAN STATION.—The permanent way and the platforms of the old station having been renewed since the recent fire, the company intend to make it serve until the new station is built. This will be several months at least. Messrs. Kinnear, Moodie, & Co., who carried out the enlargements at Perth, have been entrusted with the contract. The new station will be about 800ft. long and 180ft. broad. The roof will be a single span resting upon girders.

SHIPBUILDING.—The shipbuilding yards on the Clyde are being rapidly denuded of the vessels on their stocks, and at Greenock large numbers of men have been paid off as the yards have been emptied. Very few orders are in the market, and prices are so low that both shipbuilders and shipowners evidently anticipate a serious depression. The amount of work on hand at present is about 170,000 to 180,000 tons. This is over 90,000 tons less than the amount on hand at this period last year. Then, new orders were being booked, and work was being refused owing to the difficulty of executing contracts within the required time; now there are practically no fresh bookings.

REDUCTION IN WAGES.—The Fairfield Engineering and Shipbuilding Company have intimated to their workmen that a reduction will be made in the rate of their wages. It is not yet known what the exact extent of the reduction will be; it is understood that the reduction will not take effect until after the Fair holidays. Then, however, it appears not unlikely that the reduction will be general. It is understood that the wages of joiners at the Fairfield Works are to be reduced ½d. per hour, and the workmen in the other departments at the same rate.

TECHNICAL SCHOOL AT COATBRIDGE.—A technical school is being established at Coatbridge, the seat of the iron smelting industry in Scotland. The foundation stone of the building will be laid in a few days.

EXTENSION OF THE TELEPHONE SYSTEM.—The telephone system in Scotland has been extended by the establishment of a direct line between Edinburgh and Dundee. This line will be shortened at an early date by the running of a line across the Forth Bridge. The National Telephone Company have also established a trunk line from Edinburgh to Galashiels, Selkirk, and Hawick, and have just increased the number of trunk lines between Edinburgh and Glasgow by two additional lines. The revenue of the company now reaches the large sum of £400,000 per annum.

(From our own Correspondents.)

LIVERPOOL, 25th June, 1890.

THE MARINE ENGINEERS' MOVEMENT.—The marine engineers of Liverpool intend making a demand, on the 1st of July, for an increase of wages, and also for the number of men engaged on steamers to be in proportion to the tonnage of the vessel and the power of the engines. They contend that, as they have practically the charge of costly ships, cargoes, and hundreds of passengers, they are entitled to the demands which they are about to make, especially as very little credit is given them for their services. A new tariff of wages has been drawn up and received the sanction of their society, and they feel very sanguine that the

Digitized by Google

masters will accept their terms. The members of the Sailors and Firemen's Union in Liverpool and Birkenhead have also given notice that they intend adhering to the resolution, passed last week, not to sign articles with non-union men after the 1st of July. It is stated by the officials of the union that similar resolutions have been carried into effect at other ports for a considerable time.

SHEFFIELD, 25th June, 1890.

Iron and Steel Trades.—Business still continues satisfactory on the whole. Pig iron, which has fallen so much in value for the last few weeks, is now much firmer; one very large establishment has found a purchaser for some thousands of tons at 53s. 6d. There is evidently a feeling of distrust, however, as two blast furnaces in the district have been blown out for repairs. There are plenty of large contracts waiting to be given out in railway work. The Great Northern Railway, the Manchester, Sheffield, and Lincolnshire Railway, and Great Eastern Railway are wanting material; the Argentine Republic are also asking tenders for rolling stock and marine work. Messrs. John Brown & Co., Limited, have secured the contract for crank and straight shafting of the "Acolus" and "Brilliant," to be engined by Messrs. Hawthorn, Leslie, & Co., Newcastle; the firm will also supply "Purves" flues for the boilers. The Parkgate Iron and Steel Company have completed the extensive additions to their plant. Four 25-ton Siemens furnaces have been erected. Their new rolling mill is probably one of the best fitted up mills in the world; the largest rolls weigh about 25 tons, and are hydraulically balanced, the weight being put on by small reversing engines fixed to the housing tops.

Coal and Coke.—Coal and coke are rather quiet. Coal is rather firmer than last week. The railway contracts are now settled, and the average price to be paid is 10s. 6d. per ton.

LEICESTER, 25th June, 1890.

Wool Spinning and Yarn Trades.—There is, unfortunately, little alteration of the local wool market in the direction of improvement. Business remains in the same quiet and uncertain state as for some time past. Users are content to buy the smallest parcels to satisfy their wants. Prices are as uncertain as ever, and this effectually curtails business in the direction of any speculative purchases. It is probable that the Colonial wool sales this week will give some indication of the average prices, and it may be that the local wool fair held this week will further settle prices. Spinners are moderately busy, but the uncertain prices of the raw material seriously affect the placing of new orders. There is most doing in worsted yarns; some good contracts for these are in hand, for both home and foreign markets.

Hosiery Trade.—This department shows no great advance on the recent small improvement, and the trade on the whole is hardly up to the average. Some good orders are on hand for heavy Shetland goods and for natural wool goods, but in the fancy departments and in cotton hosiery there is room for much improvement.

Boot and Shoe Trade.—Manufacturers are still able to keep their workpeople fully employed, and a very large turnover is being made. But orders are not coming to hand now quite so freely as they have done. The shipping branch of the trade has not been so good this year as last, and it shows few signs of immediate improvement. Leather merchants are doing a good, steady trade. There has been an advance in the price of several descriptions of American leathers, and some little speculative trade has been done in view of a further advance, but that has subsided, and buyers are content to buy only for present wants.

SWANSEA, 25th June, 1890.

The Electric Light.—The work of lighting the whole of the Swansea Harbour Estate by electricity has just been completed, and the docks are now lighted nightly by the new illuminant. The installation has been chiefly carried out by Mr. Polyblank, the assistant engineer to the Trust, who has refitted the engines of the old Abertawe dredger to obtain the necessary motive power. At a meeting of the lighting and electrical committee of the Cardiff Corporation it was decided that the Council be recommended to apply for a provisional order to Parliament for the supply of the electric light within the county borough of Cardiff. In this connection it may be mentioned that by a majority of seventeen to five the general purposes committee of the Cardiff County Council rejected the recommendation of the lighting committee that the Cardiff gasworks should be purchased by the county borough for the sum of £505,000.

Local Dividends.—Messrs. W. H. Hancock & Co., Limited, brewers, have decided to recommend a dividend at the rate of 23 per cent. per annum for the last half-year. Messrs. John Bland & Co., Limited, timber merchants, pay 5½ per cent., which, with the interim dividend of 2½, makes 8 per cent. for the year. The Bute Shipbuilding and Dry Dock Company's report shows a profit of £20,789, and enables the directors to pay a dividend of 7½ per cent. for the year.

Re-starting of Briton Ferry Works.—A blast furnace has been re-started at Briton Ferry. The furnace has been re-modelled by the Briton Ferry Works Reconstruction Company for the making of hematite pig iron.

The Dockers' Strike.—The strike at the Swansea Docks, which lasted from Saturday night until Thursday last, has ended in a complete victory for the men. In consequence of this disturbance to trade the gross tonnage of imports and exports shows a decline of 34,000 tons compared with the previous week.

The Sliding Scale.—The decision of the masters, just made known, to terminate the sliding scale agreement for governing colliers' wages in South Wales and Monmouthshire has caused widespread surprise, not to say consternation, in view of the possible consequences.

CARDIFF, 25th June, 1890.

Iron and Steel.—Hematite pig iron shows a better tone, and some makers who had intended to put out some of their furnaces have decided to continue working, in the hope of business becoming consolidated. Steel bars are quoted at £5 10s. Business in steel rails is moderately active, but there is no disposition amongst buyers to contract heavily.

Coal and Coke.—The steam coal trade is even better than last week. Shipments have amounted to 270,000 tons, which is very close to the highest weekly figures ever reached. Colliery owners, with one or two exceptions, are booked forward for three or four weeks, so there is no prospect of a decline in prices for some time to come. Steam coal, first quality, is firm at 15s. 6d. to 15s. 9d.; seconds, 14s. to 14s. 9d.; and third, 13s. to 13s. 6d. Small steam is firm, at 9s. 6d. to 9s. 9d., and households, at 13s. 6d. to 15s. The coke market is without appreciable change.

BARROW-IN-FURNESS, 25th June, 1890.

Hematite Iron.—There have been fluctuations in the hematite pig iron trade during the past week, which, however, have left the market as before in a weak state. Prices of warrants stood at 51s. 9d. per ton, but makers are asking 55s. for mixed numbers of Bessemer iron net f.o.b. The output of the district has been further reduced by two furnaces at Maryport and two at Barrow being blown out, but an additional furnace has been lit at Cleator, and one at Workington. It is generally believed that it will be found necessary to damp down at least another half-dozen furnaces, so that the prospect cannot be considered bright.

Steel.—Little activity is observable in the steel trade. Orders for rails are not numerous nor of an important character, and prices of heavy sections still range from £4 10s. to £5 per ton. There are rather better prospects in the steel shipbuilding material trade, but blooms, slabs, billets, wire rods, tinplate bars, and merchant steel generally, show a very quiet tone, and prices on the whole are rather weaker.

Shipments.—The shipments of pig iron and steel from West Coast ports amount to 13,877 tons as compared with 20,885 tons for the corresponding week of last year, a decrease of 7,008 tons. Up to date 506,461 tons have been exported against 523,128 tons last year, a decrease for 1890 of 16,667 tons.

Reduction of Stocks.—Stocks of hematite warrants have been reduced during the week to the extent of 4,178 tons, and from the 1st of January last 86,171 tons. The total amount still held is 294,473 tons.

MIDDLESBROUGH, 25th June, 1890.

Pig Iron.—The market has been more active this week than we have had it for several months, and makers have done a large amount of business at prices 1s. per ton above those ruling last week; 42s. 6d. for prompt f.o.b. deliveries of No. 3 Cleveland G.M.B. is their regular figure, and in some cases 43s. has been secured. The prospects are undoubtedly good, though the warrant market is somewhat easier, and buyers are showing a disposition to purchase for delivery two or three months forward. It is not easy to get No. 3, either from makers or the warrant stores. Forge qualities are more plentiful, and are relatively cheaper than No. 3, for grey forge can be got at 41s. The stock of iron in Connal's public warrant stores is declining much less rapidly than it did last month, and the decrease this month so far has only been about 11,000 tons, a little over 95,000 tons being now held. The competition among local hematite pig iron makers has become less keen, and 55s. is the lowest that is asked for mixed numbers.

Pig Iron Shipments.—It was expected that June would be a very quiet month as regards exports, but the prophets have found themselves agreeably disappointed, seeing that so far the shipments are above the average of this period of the year, no less than 60,910 tons having been exported this month up to the 23rd, as compared with 60,183 tons to the 23rd May. To Scotland the shipments of Cleveland iron this month have been better than for some time past, but as the difference between Scotch and Cleveland has again got below 3s. per ton, we must expect the Scotch founders to take less Cleveland iron.

Manufactured Iron and Steel.—The improved tone in the finished iron market continues, and producers have less difficulty in keeping their establishments going regularly. The downward tendency of prices is checked, and some expect even an upward movement before long; indeed, some firms are asking more than they quoted a fortnight ago, the improvement being noticeable in steel rails and common bars. Inquiries for heavy rails are received from Canada and Australia, and small rails are wanted for plantation purposes. Common iron bars are £5 12s. 6d., best bars, £6 2s. 6d.; ship angles, £5 2s. 6d.; ship plates £5 7s. 6d., all less 2½ per cent. Heavy steel rails are £5; steel ship plates, £6 7s. 6d.; and steel angles, £6 2s. 6d. Cast-iron railway chairs are £3 10s.

Wages.—The Cleveland ironstone miners have agreed to accept till the end of August a 10 per cent. reduction in wages, and the blast furnace men, who had given notice of a termination of their wages sliding scale on the 28th inst., will agree to its renewal till the end of August. It is expected to bring a reduction of wages at the next ascertainment.

NEWCASTLE, 25th June, 1890.

Race Week Holidays.—Another of those frequently recurring holiday periods which tend so greatly to disorganise trade commenced yesterday, and for the remainder of the week the whole of the works in the district will be closed to give the operatives an opportunity of attending the annual race meeting at Gosforth. This course is pursued in accordance with old custom, and it is beyond a doubt that if the employers did not voluntarily permit the temporary cessation of operations for the purpose indicated the men would absent themselves without leave, and the employers would thus have the evil of insubordination to deal with as well as having to put up with the interruption to business. It is only by the help of the trade societies' governing authorities that the employers could bring any effectual pressure to bear on the men in the way of minimising the evil of prolonged holidays, and it is to be hoped that this kind of assistance, which has hitherto been given but stintingly, will in time be more freely accorded.

The Iron Trade.—There are evidences of greater firmness in the iron trade, and the general expectation in commercial circles appears to be that an improvement, though not a substantial one, is at hand. Stocks of pig iron are undoubtedly diminishing, and prices are tending upwards. Fluctuations in the value of this commodity, however, are of pretty frequent occurrence, and a small advance of prices does not afford much basis on which to found hopes of a general improvement. When the value of finished iron enters upon the stage of enhancement, speculations regarding the return of busy times may be entered upon with some approach to confidence, but up to the present the price of finished iron remains at the point where it has stood for several weeks past, and there does not seem to be any immediate prospect of a change.

Ordnance Works.—Messrs. Armstrong, Mitchell, & Co. are understood to have received further important orders for guns and their accessories, and the whole of the departments are now kept on the system of double shift. An immense new shop, that has been fitted up with effective modern machinery, has recently been opened, and the building of other shops is now in progress. Very little more, however, can be done in the way of extension of premises, all, or nearly all, the available ground being now covered, and in the immediate future the company will have to content themselves with what can be done by the continuous running of machinery and the acquisition of new labour-saving appliances. The building of the new ordnance works in connection with the shipbuilding yard and steel and iron mills of the Palmer's Company at Jarrow has been commenced, and as the execution of the contract will be pushed on with all possible despatch it may be looked upon as a certainty that the premises will be ready for occupation early next year.

The Coal Trade.—The shipments of coal and coke at Tyne Dock for the week ending June 21st amounted to 120,109 tons, being an increase of 16,696 tons as compared with the shipments for the corresponding week last year.

BELFAST, 25th June, 1890.

Shipbuilding and Engineering.—The stocks are still all filled, but there is evidence of a general slackness creeping over the trade. No new orders of any importance have been placed since the beginning of the year. Those which have been booked have been for small vessels to meet the requirements of the local trade, and do not point to any improvement in the general shipping trade. Inquiries for new steamers are made from time to time, but these are merely to test the state of the market. Wages still continue at their height, and no notice of reduction has yet been given, but the supply of labour is much increased. Engineers and boiler makers continue busy, and some good foreign orders are in hand. Machine makers are fairly well employed.

Main Drainage Scheme.—This important sanitary work is now making rapid progress. The tender of Messrs. H. & J. Martin, Limited, for No. 3 contract, for the completion of the pumping station, has been accepted, the amount being £6,395.

Linen Trade.—The proposed alteration in the American tariff still gives a degree of uncertainty to business, and sales have been much affected by it. However, latest advices are of a much more favourable character, and it is hoped that things will soon regain their normal condition. The latest proposals—*i.e.*, to add 5 per cent. on all goods up to 90s., and leave the finer sets unaltered—would make but little difference in the sales. Prices continue firm, and transactions are only for present requirements. No purchases on speculation are reported. Advices of the flax crop are most satisfactory, and although the average is below last year's, it is expected that both the quantity and quality will be in excess.

THE SPIEGELBERG FLAX SCUTCHING MACHINE.

CONSTRUCTED BY MESSRS. URQUHART, LINDSAY, & CO., DUNDEE.

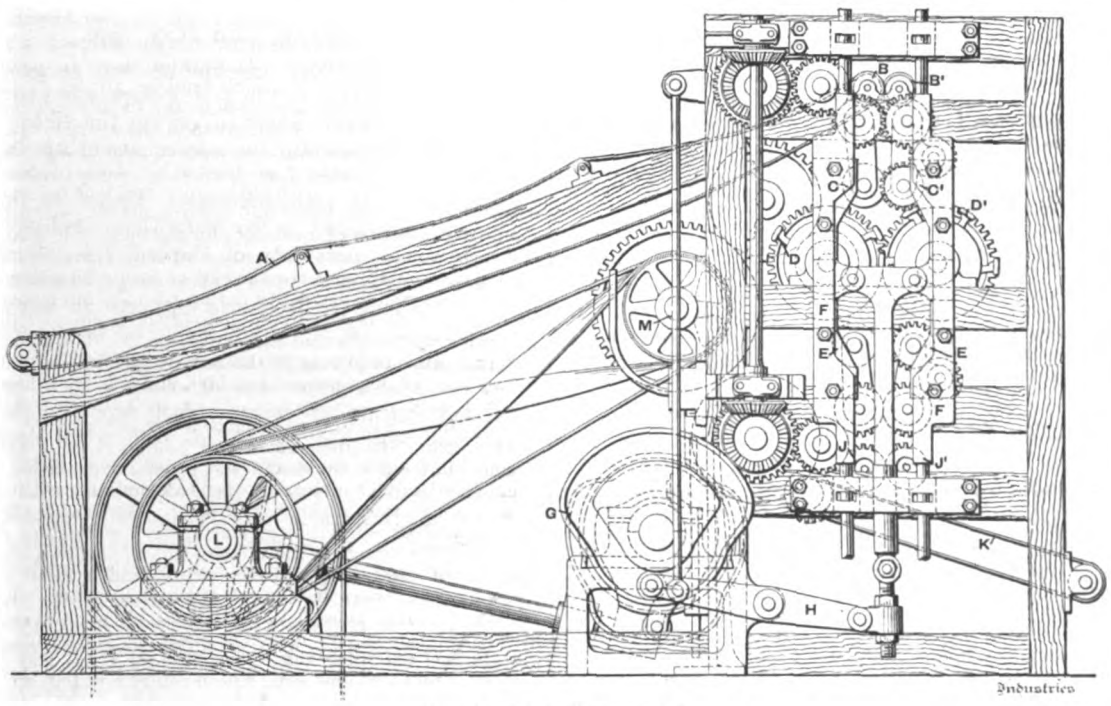

FIG. 1.—SIDE ELEVATION.

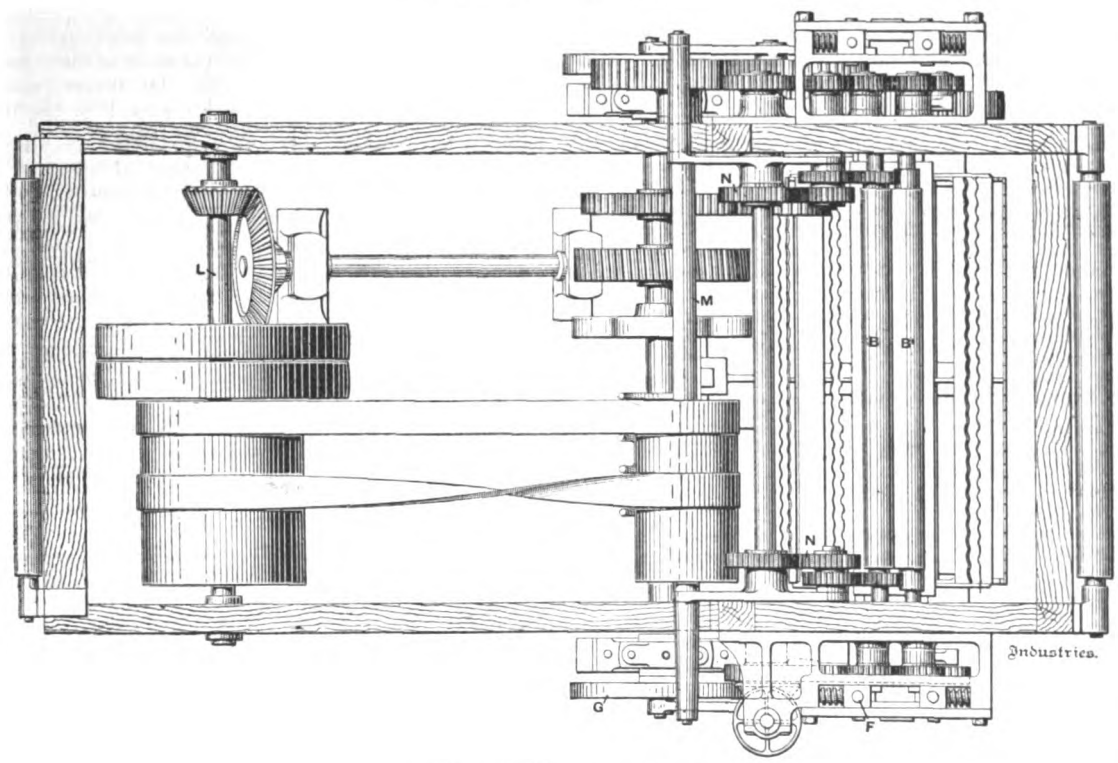

FIG. 2.—GENERAL PLAN.

THE LIVERPOOL ENGINEERING SOCIETY.

THE first excursion this season of the above Society took place last week, when nearly thirty of the members journeyed by train to Keswick, arriving there on Friday evening. After dinner a visit was made to the works of the Electric Supply Company, which are situated about a mile from the town. A representative of Messrs. Fawcus & Cowen—the engineers for the scheme—explained the working of the system; and as this possesses some novel features, we hope to describe it more fully at an early date. It is on the high-tension system, and the dynamos are driven by turbines supplied by water from the River Greta, which flows through the town. Most of the hotels, public buildings, residences, &c., are supplied with the light, and it is giving great satisfaction. On Saturday the party drove to Thirlmere, where they were met by Mr. Hill, the resident engineer for the new Manchester Water Works, who conducted them over, and explained the various works in progress. The excavations for the dam at the foot of the lake, which is to impound the water, was first visited, and was of considerable interest on account of the nature of the rock which has to be removed. The boring for the discharge culvert was next visited, and the action of the Larmuth pneumatic drill, which is being used for the boring, was observed. The tunnels were afterwards inspected, the one through Dunmail Raise being nearly completed. The boring is principally through rock, and when it is of a shaky nature it is lined with brickwork; the section of the tunnels is circular at the top, with a flat floor. The valve and straining wells were next examined, and after a visit to the siphon wells at Ambleside and a portion of the pipe line, the technical part of the visit concluded.

THE SPIEGELBERG FLAX SCUTCHING MACHINE.

WE had recently an opportunity of inspecting a new flax scutching machine, which has been invented and patented by Mr. Arthur Spiegelberg, of Dundee. Before we describe the machine, it may be well to state that when flax is pulled the stalk may be said to be made up of three distinct parts. In fact, it resembles a beech tree; there is first the wood, then the bark, and lastly the glossy varnish of the bark. The woody matter in flax is of no value; the difficulty is how to get rid of it, and to save the bark. To accomplish this the flax must be retted, and it is either spread over a field and exposed to the weather for some time, which is called "dew retting," or the straw is steeped in water. In a short time the vegetable part rots, the gum on the outside dissolves, and the stalks are taken out of the water and dried. But the wood is like a fixed finger inside a glove, and, although weakened, has still to be removed. Scutching is the process by which the wood is removed and the outside skin saved. The difficulty is to get the woody part out without injury to the skin, which is *the* valuable part of the plant and forms the flax fibre. There are four methods of doing this. The first is by striking the flax repeated blows, then taking it in handsful, holding it over a wooden rest, and striking it sharp blows with a wooden blade. This is hand scutching, and has been fully described in *Industries* (see Vol. V., page 420). The second plan is to run the retted straw through fluted iron rollers, and when the heart is thus broken into short bits, to take the straw in handsful, and hold it against two end blades rapidly revolving upon a shaft. This is mill scutching (see *Industries*, Vol. V., page 420). The process known as the "Cardon" process (see *Industries*, Vol. III., page 387), and which promised great things a short time ago, consists in pricking the straw with needles. This cuts the straw into lengths so small as to make it practically dust. The straw comes easily away. But it is obvious that the skin is damaged at the same time, because the heart of the stalk must be got at through this outer skin. The "Wallace" patent (see *Industries*, Vol. V., page 328) is another application of the pricking process.

The breaking machine of Mr. Spiegelberg, which we illustrated in the Patent Abstracts of our issue of the 16th of May, is a novel departure from the older processes. The flax straw is fed into the machine, one end always overlapping the preceding one. Heavy fluted rollers flatten the tubular stalks, which action does not spoil the fibre, but only takes the resistance out of the straw. Then the flax proceeds to the small rollers, lightly fluted, just sufficient to obtain a thorough grip of the flax, and by means of suitable mechanism these rollers receive a lateral or shaking motion which bends the stalks and allows the wood to fall out, and also prevents the outer skin from becoming crushed or cut, as is the case with the needle points, or the series of fluted rollers—run at a high speed—of other machines. The fibre then passes to the second part of the machine, as illustrated herewith, which somewhat resembles an intersecting heckling machine. The "strike" of flax is secured between a pair of indiarubber gripping rollers C C^1, which bring it into contact with a pair of rapidly revolving beaters D D^1. After this operation has gone on for a given time, the beaters are caused to revolve in the opposite direction, the gripping rollers C C^1 and E E^1 are respectively automatically opened and closed in the interval by means of cam bars F F^1, the cams G, and levers H. In this manner both ends of the strike are sufficiently operated upon before they are allowed to proceed downward to the delivery roller J J^1, and thence to the delivery apron K. L is the first motion shaft, carrying fast and loose pulleys, connected to similar pulleys on the shaft M, from which the beaters are driven. The taking-in rollers B B^1 derive motion from suitable gearing N, which is so constructed as to allow itself to become automatically disengaged upon the reversal of the machine.

The principal part of the process, however, is that involved in the breaking machine, which cannot be substituted by hand or other process, whilst the cleaning might be done in the ordinary way; in fact, when the flax is well retted the breaking is done so completely that a little handling cleans the fibre entirely from all shove. The two machines may be worked separately. It is obvious that, the fibre being uninjured, there is a much larger yield of fibre, and the heckle gives far more yield in line. About the importance of scutching there can be no question. Vast countries produce grasses and fibres which are of the highest value. The difficulty always has been to separate the fibre from the gummy exterior, and from the inside pith or wood. This machine may therefore become of the very highest importance, and further trials on a practical and commercial scale will be awaited with very deep interest by those connected with the flax trade.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week.

All accounts are payable to GEO. CAWLEY, 358, *Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

Industries:

FRIDAY, 27TH JUNE, 1890.

THE LOAD LINE ACT.

THE mercantile marine of this country has occupied a much larger share of the attention of Parliament during the past twenty years than in any other similar period of our national history. Considering that the greater part of the legislation relating to merchant shipping, which has been the outcome of that attention, is of a restrictive character, it is very remarkable that British tonnage should have simultaneously increased at a higher rate than when the business of the shipowner was severely let alone. It is not suggested that there is any association of cause and effect in the facts we have just recorded. On the contrary, it is very probable that but for the agitation conducted by Mr. Plimsoll there would be a greater tonnage of merchant shipping afloat at the present day than is actually the case. One thing, however, is certain, that, but for him and the legislation which he dragged out of Parliament, the shipping casualties of the past fifteen years would have reached far more appalling figures than those which even now distress the minds of people who give these matters their attention. The fact is that Mr. Plimsoll commenced his agitation against the employment of unseaworthy ships just at the period when wood was finally being superseded by iron for ship construction. Prosperous shipowners had for some time been selling their wooden ships and building new ones of iron, and these wooden ships had in many cases fallen into the hands of comparatively poor men, who sought for bargains, without having the capital to enable them to keep the ships in proper repair when they got them. The consequence was that, as old wooden ships require frequent overhauls in order to keep them efficient, the mercantile marine became rapidly crowded with unseaworthy vessels. The competition of steamers had, too, brought down freights to a low rate, and this contributed to further distress the men whose property consisted entirely of old wooden ships. Much as he was maligned at the time, Mr. Plimsoll did a valuable service to humanity when he caused the Government to interfere by detaining unseaworthy ships in port, and in eventually causing them to be broken up.

Having freed our merchant navy from the taint of rottenness, Mr. Plimsoll next felt it his duty to save seamen from other dangers which attend the pursuit of unholy gain. The chief of these is overloading; and when we bear in mind that every extra ton of cargo which a ship carries is an additional source of revenue to her owner, for which he pays scarcely anything appreciable in the form of extra wages, coals, or stores, and nothing extra in working capital, it will be evident that the disinclination to stop pouring in cargo at the hatchways is, with many shipowners, very great. And this disinclination has always been stimulated by the vague uncertainty which surrounded the problem of what is a safe loading for a ship. That the line between safe and unsafe loading must exist somewhere on a vessel's side all shipowners would admit; but then, they would ask, where is that line, and who is able to fix it with accuracy? And so with this excuse of uncertainty, and in the absence of authoritative pronouncement on the subject, a shipowner might say that his opinion was as good as any other person's, and in giving expression to that opinion he was not likely to err on the light side. To further complicate the matter steamships began to assume peculiar forms, such as were unknown in the days of sailing vessels. Either to dodge tonnage assessment or to make deep loading less apparent the ingenuity of shipbuilders and shipowners evolved new types of steamships, to which the rules of thumb for freeboard hitherto in use were inapplicable. With the old-fashioned sailing ship a rough and ready approximation to the height of side out of the water was determined by allowing so many inches of side per foot depth of hold; but what was the use of this rule when dealing with well-deck steamers or those with spar and awning decks? It was just coincident with the advent of these new types that the long-talked-of legislation in regard to the safe loading of ships became the subject of popular agitation. For many years all attempts at laying down rules for the freeboard of ships had been opposed by shipowners, upon the grounds that no regulations could be framed which would apply fairly to every case. Let each ship, said they, be judged upon her merits, and not only each ship, but also each cargo she may carry, the mode of its stowage, and even the nature of the voyage she enters upon, with the time of year, and every other condition which can affect the question. This, let it be remembered, was the argument put forward in the days when the sailing ship with a poop and top-gallant forecastle was the prevailing type, and when ship differed from ship more in regard to her form below water than in any other respect. What, then, about assigning hard and fast lines of freeboard to the many types of steamers which have of late sprung into existence? What about judging every ship upon her merits to-day? Surely, if the problem of the load line was a difficult one twenty years ago—so difficult, in fact, as to deter the officials of Lloyd's Register from meddling with it—what must it be to-day? A walk round the shipyards on such a river as, say, the Clyde, will show in course of construction three-decked, spar deck, awning-deck, shade-deck, shelter-deck, and well-deck steamers. There will be found sailing ships with short poops and top-gallant forecastles, and some with bridge houses besides. Beside them will be seen steamers with long bridge houses and short poops and top-gallant forecastles; others with raised quarter-decks and sunk fore-castles; some with raised quarter-decks joined to bridge houses, and some with no bridges at all; while others, again, will have a combination of top-gallant forecastle, bridge house, raised quarter-deck, and poop besides. Then, let it be further borne in mind that there are iron ships and steel ships, and that with both iron and steel there are various modes of construction, some of which are superior to others.

What would at first sight appear as the greatest obstacle in assigning a fair load line to each of these different classes of vessels will, upon closer examination, be found to furnish the most cogent reason for legislation upon the subject. So long as mercantile ships were of a tolerably uniform type, the common experience of sailors might be accepted as a fairly safe guide in fixing the depth of their lading; and there can be little doubt that, before the steamship became a keen competitor with the sailing vessel, the latter was, as a rule, laden to a safe immersion. It is the great variety in the types of ships, and the variety therefore of their qualities as regards strength, stability, and general seaworthiness, which

Digitized by Google

renders it more than ever necessary for a presiding and competent authority to regulate the depth of their loading. This necessity was foreseen by the Committee of Lloyd's Register of Shipping so far back as fifteen or sixteen years ago, and their officials drew up at that time a series of Tables of Freeboard which formed the basis of the rules laid down by the Freeboard Committee in the year 1885. These rules of Lloyd's Register were determined upon the twofold considerations (1) of experience and (2) of calculation. The mercantile marine was appealed to for its best practice and safe results, and the data so obtained was supplemented by calculations of strength and stability. Upon the foundation so formed the Freeboard Committee built up that creditable structure which is now the highest existing standard of reference to guide shipowners in regard to the loading of their vessels. The Act to amend the Merchant Shipping Acts relating to the Load Line, which received the Royal assent on the 9th inst., makes that standard no longer optional, but compulsory, for all vessels flying the British flag. After the 9th December of this year no British vessel will be able to enter outwards without producing her load line certificate; but this provision of the Act will not be extended to ships registered in a British possession until six months afterwards. There are, however, two principal points in its provisions, which are left somewhat open and indeterminate, and one of these is of the greatest importance in regard to the future working of the measure and its successful operation. These points are (1) the extent of its application and (2) the mode of its administration.

It is sought by all who realise the importance of legally fixing freeboards in the interest of safety of life at sea to bring all vessels, both foreign and British, under the operation of such a restrictive law, and in pursuit of that object our representatives at the recent Maritime Conference in the United States sought to obtain an international agreement to that effect, but without success. While provision is made in the Act that under certain circumstances the State may interfere in preventing foreign vessels dangerously overladen from leaving British ports, it is evident that without the full concurrence of other Powers we can do nothing of an effectual character in putting a stop to overloading except in ships owned by British subjects. It is alleged that foreigners do not load their ships so deeply as we do, and that the casualties in the mercantile fleets of other countries are fewer in proportion to tonnage than in our own. Statistics may, perhaps, show this to be so, but observation points to a different state of affairs. Certainly, if the casualties among foreigners are comparatively few, it is not because of anything connected with their loading. The principal point remaining to be determined is, however, that of the mode of administering the Act just passed. At the present time shipowners are at liberty to place their freeboard discs wherever they please, but should disaster overtake their vessels, and it be proved that the latter were laden deeper than the Freeboard Committee's Rules and Tables would indicate, they find themselves in a very awkward plight. Either from an honest desire to load their ships fairly, or through a prudent anxiety to keep themselves out of trouble, a great many shipowners have accepted the Freeboard Committee's Tables, and had their ships' discs marked thereby. Two public bodies are at present empowered to interpret and apply those Tables—viz., the Board of Trade and Lloyd's Register of Shipping—but, as a matter of fact, the duty has almost entirely fallen upon the latter. This is probably due to the circumstance that the Board of Trade have not such a staff as would be required for dealing with the subject, and consequently they prefer that the Society which had the chief hand in constructing the Tables should have the further labour and responsibility of interpreting and applying them. Be this as it may, the fact remains that Lloyd's Register have assigned more than three thousand freeboards, nearly all of which are recorded in their Register Book. That these records have been made further shows that the shipowners have not much, if any, cause to complain of the Society's action in the matter.

It should be clearly understood that the assignment of a freeboard by the Freeboard Committee's Rules and Tables is not like working with a ready reckoner or with a slide rule. There are very few ships presenting so simple a case for treatment that the "wayfaring man," even if above the average intelligence, could determine her freeboard from these Tables. The Rules and the Tables decide a very great deal, but then it is necessary to know something about the ship over and beyond the facts which the Tables take hold of. She may be of relatively unstable proportions or have elements of weakness in her construction. She may be old and neglected, or she may be new and strengthened beyond what is usual in vessels of her type. There are, in fact, a multitude of considerations to be noted in assigning a safe freeboard and one that is scientifically fair between ship and ship. Upon all these grounds, then, it will be seen how important it is, now that Parliament has determined upon a compulsory freeboard for British ships, that it should at the same time entrust the administration of the measure to a competent authority. The Act provides that "The Board of Trade shall appoint the Committee of Lloyd's Register of British and Foreign Shipping, or, at the option of the owner of the ship, any other corporation or association for the survey or registry of shipping approved by the Board of Trade, specially selected by the Board for that purpose, to approve and certify on their behalf, from time to time, the position of the freeboard disc, &c." This arrangement will evidently permit of more than one one authority acting at the same time; but to us it seems that the wisest course is to leave the administration of the Freeboard Act in the hands of one central public body, whether it be the Board of Trade or Lloyd's Register, or a department in which the two are combined. If it be decided to confer the power of interpreting the Freeboard Tables to other authorities than these, then it is most important that every care should be taken to ensure that such authority is competent, and that their decisions do not clash with each other. To us it appears that a uniformity of result cannot possibly be attained with several assigning authorities acting at the same time, and that the operation of such a system would lead to endless confusion and trouble. Above all, it is essential that the element of partiality to ships or persons should be entirely absent. Lloyd's Register of Shipping, as a voluntary association, lives upon nothing but the confidence of the mercantile world, and when once it forfeits that confidence its decline will commence and it will soon cease to exist. And so it will be in regard to whatever other body has delegated to it the duty of assigning freeboards to ships under the new Act. If that body inspires the shipping community with confidence it will continue to exercise its functions usefully; but if the contrary is the case there will be no finality in the matter.

THE INSTITUTION OF ENGINEERS OF JAPAN.

Recent advices from Japan give us an account of proceedings in that country which will be of interest to engineers and others who study the developments of technical education and its applications to engineering. It is now seventeen years since the Imperial College of Engineering, Tokio, was instituted, and a little over ten since the first graduates completed their course. At the first graduation ceremony Mr. Henry Dyer, who was the first Principal and the organiser of the College, in his address to the students, suggested the foundation of an Institution of Engineers somewhat on the lines of those in this country, and he subsequently drew out and printed a set of regulations to guide those who were likely to be the first members of the Institution. The matter was taken up with great energy and spirit, and the new Institution was organised and managed without further foreign assistance. For some years the members were entirely graduates of the Imperial College of Engineering, but when the Public Works Department was abolished, and the College was incorporated with the University, the Institution was placed on a wider basis, and members were admitted who had studied in other colleges at home and abroad, or who were otherwise qualified, and the Institution of Engineers is now one of the largest and most prosperous in Japan, having one thousand members in the departments of civil, mechanical, electrical, mining, and chemical engineering, and in those of architecture, metallurgy, and naval architecture. At the beginning of May there were held a series of meetings of various kinds to celebrate the tenth year of the existence of the Institution, and the further fact that it had now 1,000 members. The extraordinary session of the Society lasted six days, and was evidently planned in imitation of the meetings of the British Association and similar Institutions, and was carried out with as much *éclat*. The programme included banquets, lectures, reading of papers, excursions to works, and garden parties and picnics. A very artistic medal had been struck for the occasion, and was worn by all the members, while pocket maps and programmes, together with historical and descriptive accounts of the works to be visited, were distributed, and served to make the business of the gathering clear.

The President of the Society is Viscount Yamao Yozo, formerly Minister of Public Works, and to whose sagacity was due the founding of the College; its Vice-President, Mr. Watanabe Hiromoto, President of the Imperial University; its Chairmen, Mr. Shida and Mr. Nakamura, both graduates of the Imperial College of Engineering; its secretaries, Mr. Shinudza and Mr. Matsuo. Among the guests on the first day were several Ministers of State, past and present, the Directors and Professors of the various colleges, the President of the Chemical Society, and the editors of most of the leading newspapers. The proceedings were opened in the afternoon of the 3rd of May in the fine hall of the buildings which were erected for the Imperial College of Engineering, at Tora-no-mon, and which were appropriately decorated for the occasion. On the right of the President sat some distinguished guests and honorary members; on the left the officers of the Institution. President Yamao having in a few words opened the proceedings, the history of engineering education and enterprise in Japan, and the nature of the occasion of the extraordinary meeting of the Institution, was given by two of the leading members, Messrs. Tatsuno and Furuichi. In the course of his remarks, the latter announced that His Majesty the Emperor, having heard of the doings of the Institution, had generously expressed his approbation and presented $1,000 to its permanent funds. Thereafter various congratulatory addresses were delivered, and thus terminated the first part of the proceedings. The evening was taken up with a banquet in a large hall in Shiba Park, which was attended by a large number of guests and of the members who were then in Tokio. The *menu* card was a beautiful work of art, being bordered with allegorical figures of architecture, civil engineering, mining, chemistry, naval architecture, mechanical and electrical engineering, in which the old Japanese household deities had been made to do service. It had been designed and prepared by some members of the Society, and showed that engineering had not stamped out art. The toast of the evening was given by H.E. Count Yamagata, in which he commended the work of the Institution. Of special interest was the speech of the Vice-President of the Institution in honour of Mr. Henry Dyer, the organiser and first Principal of the Engineering College, and of H.E. Otori Keisuke, now Minister at Peking, who was for a long time the Director of the same Institution. Dr. Divers, Mr. Dyer's successor as Principal of the College, was asked to write to Mr. Dyer and convey to him the sentiments of regard and esteem in which he was held.

The 4th and 5th of May were partly occupied with popular lectures on engineering subjects, and with original papers in different departments. As is usual, however, on such occasions, the out-of-door attractions proved the stronger. Excursions to engineering works in and about Tokio filled the 6th and the 7th of the month, and occupied the time of the members and associates most pleasantly and usefully. The works are now so numerous, and so many invitations had been received, that several had to be declined from the impossibility of finding time to make so many visits. A full description of these excursions would occupy too much of our space, but the following series may be mentioned: (1) The Shinbashi railway works, Tokio Bay dredging operations, Ishikawagima docks. (2) Furukawa copper refinery at Fukugawa, where the Ashiwo copper is prepared for the market; fertiliser works, also at Fukugawa, where all sorts of artificial manures are manufactured, which are said to be proving very valuable to Japanese farmers; the Furukawa coke ovens; and the Kanegafuchi cotton spinning mills, which are newly erected, and are of enormous dimensions. (3)

Digitized by Google

Paper mills at Oji, where newspaper, post-card, and many other kinds of paper are made; the sulphuric acid, bleaching powder, and soda works; the Koishikawa Arsenal; and the Electric Light Company's works at Kojimachi. (4) The Dai Nippon medicine factory near Shinbashi; the steel works of the Naval Department; the Portland cement works at Fukugawa; the Senjū woollen mills. In the evening of the 7th there was a *conversazione* in the works of the Electric Light Company, to which were invited the ladies of the families of members. Many interesting experiments were shown, and the phonograph and other instruments exhibited.

The whole proceedings were carried out with remarkable order, and reflect great credit on the special committees and the secretaries. They are interesting as a striking example of what can be done in a short time, by a well-devised system of education, in practically revolutionising the industry of a country. The Institution of Engineers in Japan has already done good work in the ten years of its existence, and it is destined to have most important effects on the future of the country. We wish it all success.

THE DISASTER TO THE "CITY OF PARIS."

On Tuesday judgment was delivered by the Liverpool stipendary magistrate, with whom were Captain Bragg and Messrs. Eames and Hallett, assessors, in the case of the steamship "City of Paris." The magistrate said that on the arrival of the "City of Paris" at Queenstown after the accident she was only drawing 8in. mean draught more than when she left New York. The Court were of opinion that full provision was made to insure the ship's safety as an ocean-going steamer, and that the safety of the vessel was not sacrificed to speed. They considered cast steel to be a proper and suitable material to be employed generally in various parts of the engines, and the cylinders, piston rods, and other parts of the machinery of the starboard engine were generally of suitable material, and the engine room was properly constructed. The Court proceeded: We are of opinion that the primary cause of the casualty was the extraordinary wearing down of the bearing of the bracket which supported the extreme end of the propeller shaft, by which that end had dropped from its original and proper position about 7in.; that the fact of this bearing down of the after end, coupled with the weight of the propeller and of the shaft itself, produced a bending effect on the shaft at its forward support, co-existent with each revolution of the engine; that this probably produced rupture of the external surface, which gradually extended inwardly, and, finally, total fracture of the shaft; that the engine, being thus relieved from resistance beyond the friction of its own movable parts, would almost instantaneously have acquired a greatly accelerated velocity, the result of which would probably be sufficient, by the additional strain on the various connections, to diminish the clearance allowed between the piston and cylinder cover of the low-pressure engine at the top end of its stroke; that the cover was struck by the piston and moved off, the piston probably being broken up in the act, the cylinder being torn asunder, the condenser being seriously broken, and the destruction of the various other parts rapidly accomplished. The report refers to the admirable manner in which the captain, deck officers, chief engineer and his assistants, and the crew generally, performed their duties and conducted themselves in the trying position in which they were placed after the accident.

RUSSIAN SHIPBUILDING.

Considerable activity has been displayed for some time in connection with the Russian fleet, and it now begins to attain sufficient magnitude to make it a factor which cannot be neglected in calculating the chances in any war which may occur. The programme which was laid down some years ago is being steadily carried out, subject, of course, to the modifications which are required by the continual developments in naval science. From an industrial point of view, moreover, the movement has considerable importance, when we consider that two keels which were recently laid down for the Russian Navy are for ships of 10,000 and 11,000 tons, and of the style of the "Sanspareil" and "Trafalgar." These were recently laid in the presence of the Emperor and Empress, and a large company of notables. The largest of these ships, the "Ruric," will be 426ft. long at the water-line, 67ft. broad, and with a draught of 27ft., and will have side armour 10in. thick and deck armour 2½in. thick. She is to be built for a speed of 18 knots an hour, and will have a coal capacity for taking her 20,000 miles at 10 knots. She will be supplied with very powerful guns, and when completed will form a very strong addition to the Russian Navy. After the conclusion of the ceremony connected with the "Ruric," the Imperial party performed a similar one in a neighbouring shipbuilding yard for the armoured turret-ship "Navarino." Its length will be 360ft., its breadth 68ft., and its draught 25ft. There will be two engines of 4,500 h.p. each, with 12 boilers, and the speed is expected to be 17 knots. The armament will consist of four 12in. guns in two turrets, and there will be the usual complement of quick-firing and other guns. The next part of the day's performance was launching the new yacht for the Emperor, and which is named the "Polar Star." She has been built by Captain Kazi, at the Baltic Works on the Neva, and is intended to be used as a yacht in time of peace, but also as a despatch boat in time of war. She will be the only sea-going yacht of modern type possessed by the Emperor, as the "Livadia" lies unused in the Black Sea, while the older ship, the "Derjiwa," in the Baltic, is now out of date. The "Polar Star" is 315ft. long by 46ft. broad, with 18ft. mean draught of water, and 3,600 tons displacement, and is intended to have a speed of 16 knots. The boilers were intended for a pressure of 130lb. on the square inch—that is, for triple-expansion engines—but the Emperor has decided that the engines shall be of the ordinary compound type with a steam pressure of 75lb., showing that he is willing to sacrifice efficiency for what he supposes greater safety.

On the same day was launched an armoured gunboat 229ft. long and 41ft. deep, and having a displacement of about 1,500 tons. It is of the same type as those which are being added rapidly to the British Navy, and is intended to sweep the seas of the enemy's mercantile vessels. Besides these there are three large ships being completed on the Baltic, and a similar number on the Black Sea, while several torpedo boats are being built in Germany, St. Petersburg, and Odessa. Altogether, either for offence or defence, the Russian Navy is being rapidly developed, while the proportion of the work which is being done in the country shows that great advances have recently taken place in the arts of construction.

THE EDINBURGH UNDERGROUND RAILWAY.

The Parliamentary Committee on the Caledonian Railway Bill, which proposed to construct a tunnel along the whole length of Princes Street and under the Calton Hill, have decided that such a case of public interest has not been made out as to outweigh the serious objections of the Corporation of Edinburgh and other objectors, and have therefore rejected that part of the Bill. They have, however, agreed to pass the remaining parts, subject to some modifications. These are chiefly for the purpose of affording greater railway facilities to Leith, and none of them were seriously opposed. While sympathising with the wish to preserve the amenity of Princes Street, we may repeat the opinion which we have previously given, and which has since been supported by the strongest evidence, that if it were not for the mutual jealousies of the Caledonian and the North British Railway Companies it would be possible to make out a scheme which would afford great conveniences to the public, without interfering in any way, or at least to any appreciable extent, either with the beauty of the city or the comfort of its inhabitants. It is very probable that this question will be one of the chief points which will decide the municipal elections in November, as there can be no doubt that the present decision will be challenged.

THE LATE SIR WARINGTON W. SMYTH, F.R.S.

Sir Warington Smyth, the leading British authority on all matters connected with mines, died suddenly at his residence in Inverness Terrace, on the 19th inst. He was born in Naples in 1817, his father, Admiral W. H. Smyth, F.R.S., being at that time engaged in making a survey of the Mediterranean. He was educated at Westminster and Bedford Schools, and took his B.A. degree in 1839, at Trinity College, Cambridge. At Cambridge his academical career was a brilliant one. Having gained a fellowship he travelled for four years through the mining districts of Europe, and acquired a thorough knowledge of the Continental systems of mining. His experiences in Turkey and Asia Minor he recorded in a book published in 1854, entitled, "A Year with the Turks." In 1844 he was appointed to a post on the Geological Survey of the United Kingdom, and in the course of his professional duties surveyed the principal coalfields and metalliferous districts of England, Wales, and Ireland. On the foundation of the Royal School of Mines in 1851, he was selected as the first lecturer on Mining, and lectured every year until his death. A great part of his life was devoted to the official work on mine inspection. He was inspector of the mines in the Duchy of Cornwall, and since 1857 acted as comptroller of all the mineral properties of the Crown under the Commissioners of Woods, Forests, and Land Revenues. He was President of the Geological Society in 1866, and has been Foreign Secretary since 1874. In 1879 he was appointed Chairman of the Royal Commission on Accidents in Mines, and devoted seven years of labour to the duties of this honorary post. For this and other public services he received the honour of knighthood on the occasion of Her Majesty's Jubilee. Besides various technical reports and papers read before the learned societies, Sir Warington's chief literary work was his "Rudimentary Treatise on Coal-Mining," written in 1867, and now in its seventh edition. It is the standard text-book on the subject, and has been translated into Chinese and into the principal European languages. Besides this, he was the author of the articles on Mining in Ure's Dictionary of Arts, Manufactures, and Mines, and in Stanford's British Mining Industries. A paper he wrote in 1871, on the sinking of pit shafts by boring under water, attracted considerable attention among colliery engineers. To Sir Warington Smyth and his teaching must be ascribed a foremost share in the great progress that has taken place in British mining in the fifty-two years during which he was engaged in business connected with mining. Although he had been out of health for some months, his death was quite unexpected. He attended the Royal Society *soirée* the evening before his death, and was engaged in looking over examination papers when he died. He was an enthusiast in his work. The large pecuniary rewards offered by a career in the commercial branches of mining never tempted him. In the study of mining he found so much that was vast, so much that is worthy of man's highest powers, that he did not stop short at that point when he could obtain his worldly ends, but continued to persevere towards that goal of higher knowledge which has always been the object of the noblest of mankind.

Letters to the Editor.

WROUGHT-IRON CHIMNEYS.

To the Editor of "Industries."

Sir,—In the letter from your Paris correspondent, published in your issue of the 6th inst., I notice an account of "A Novel Wrought-Iron Chimney."

I have for several years studied the construction of tall chimney shafts, and I know a considerable number of wrought-iron shafts have been erected during the last twenty years. The one mentioned in your paper was built about 1869-70, and is fully described in my book on "Tall Chimney Construction," and previous to the building of this particular shaft MM. Schneider & Cie., Creusot, had erected a similar one, 197ft. high.

Messrs. Witherow & Gordon, of Pittsburgh, Pennsylvania, have since 1876 built upwards of thirty wrought-iron chimney shafts, varying in height from 100ft. to 190ft.; the latter they constructed for the Cleveland Rolling Mills, Ohio, U.S.A., in 1881.

Messrs. Francis & Co., Nine Elms Cement Works, Rochester, in 1878 had a wrought-iron chimney shaft erected at their works 160ft. high.

In Russia I am informed wrought-iron chimneys are very common. One built in 1874 at Adeshavo, near the town of Kineshma, is 170ft. high.

Messrs. Robert Heath & Sons' Iron Works, Tunstall, Staffordshire, have a wrought-iron shaft 75ft. high from the ground line, built up parallel, 6ft. diameter, from bottom to top.

You will see from the above, that wrought-iron chimney shafts are not so novel as many persons think.

Yours, &c.,

R. M. Bancroft,
Past-President Civil and Mechanical Engineers' Society.

London, 19th June, 1890.

HOWE'S "METALLURGY OF STEEL."

To the Editor of "Industries."

Sir,—Mr. Howe, in a recent communication to me, writes as follows:—

"Hoosick Falls, N.Y., U.S.A.
"June 9th, 1890.

"Dear Mr. ——.

"I have just been looking over your kind contributions to *Industries* on my 'Metallurgy of Steel.' I note that I have not made my meaning clear to you in one place, on page 475, top of last column, where I say that 'the former view that nitrogen or other gases played an *essential* part.' I meant essential in its strictest sense, while I think you have taken it to mean merely *important*. Now, in fact, I repeatedly point out the enormous effect that certain gases—*e.g.*, N. and H.—not only may but do have on the properties of steel.

"What I referred to in the sentence quoted above, was Fremys and similar exploded hypotheses, that nitrogen was an *essential*

Digitized by Google

element of steel—*i.e.*, that you could not have steel without nitrogen, and that it was nitrogen that made it steel. This statement of mine, moreover, occurs where I am speaking of the constitution and nature of steel.

"I do not know whether you will think it worth while to call attention to this misapprehension on your part, as you have, I think, put me in rather false position before the readers of *Industries*.

"Again, on page 451, second column, I think that if you had weighed my words a little more closely, you would have seen that you and I are more nearly of the same mind than you have given your readers to think. Indeed, I think that you and I think very closely alike on these points. Now what I said referred to the '*intimate* knowledge which the public and many non-metallurgical engineers, &c. &c.' I do not suggest that metallurgists have no knowledge, nor that they have not a fair knowledge, but merely that they have not so intimate a knowledge as they are credited with.

"Nor is it true that I think that analysis can do little for the steel-maker. I do not think, but I *know*, that it can do much; my contention is that it cannot do everything, and that it cannot do so much as is expected of it by many, or perhaps by most. So while I think that you have treated my work in the fairest and most friendly spirit, and while I feel very much gratified and complimented by your contributions, I think that you have not caught my meaning in the passages which you criticise. This, I believe, is in part due to the necessary condensation in a treatise, and to the fact that the work, appearing in instalments, is not so readily grasped as when in book form.

"Thus, as to the resemblance between iron and crystalline rock, I give in a later chapter a great deal of evidence supporting my view. This, I think, can hardly have been before your mind when you speak of it as you do.

"Yours faithfully,
"HENRY M. HOWE."

With regard to the general merit of Mr. Howe's work, I can only reiterate that its value must be inestimable to all concerned in iron and steel manufacture. I think Mr. Howe has very fairly met my criticisms, and it remains only for your readers to judge for themselves. Yet throughout the book there is much matter which cannot well be dealt with unless fully discussed; and in the interests of all the sooner this is done the better.

Mr. Howe has given us so much fresh matter for consideration that we cannot do better than show our appreciation by applying our best energies, together with such knowledge as we possess, to the elucidation of much problematical matter which, as he himself says, may be due to the necessary condensation in a treatise, and therefore needs further amplified discussion.

I hope shortly to specially review the section on gases in iron and steel, mainly, however, with the object of contributing some facts and experiments on a subject at which I have been working for a long time, and have had considerable experience.

Yours, &c.,
METALLURGIST.

South Wales, 21st June, 1890.

BRITISH MANUFACTURES ON THE CONTINENT.

TO THE EDITOR OF "INDUSTRIES."

SIR,—I did not intend to convey the meaning that protective duties abroad affected us more than competing countries desirous of sending goods of the same class to any given locality, but merely that they prevented us doing business which under a system of free imports we should be able to transact. That a greater knowledge of languages is desirable among our business men is a point which no one will dispute, but "Trader," I think, lays somewhat too great a stress upon it. Those whose trade requires the use of foreign languages employ foreign clerks, and I am consequently doubtful that any great loss of trade abroad has arisen from the causes which your correspondent states.

Yours, &c.,
T. R.

London, 24th June, 1890.

PLUMBAGO.

TO THE EDITOR OF "INDUSTRIES."

SIR,—I should be glad if any of your readers could give me information as to the lower grades of plumbago or blacklead, and what percentage of carbon is contained and required in those grades most used for other than the manufacture of pencils.

Yours, &c.,
GALICIA.

Galicia, 21st June, 1890.

Reviews.

TECHNICAL EDUCATION IN ENGLAND AND WALES. London. 1889.

The Secretaries of the National Association for the Promotion of Technical and Secondary Education have prepared a report to the Executive Committee on the existing facilities for technical and scientific instruction in England and Wales, which will be found most useful to all who are interested in the subject. and who have not time to study the details of Blue Books. The information given as to secondary and higher institutions is somewhat meagre, but the authors hope in another report to grapple with some part of this wide question more fully. The report is divided into three sections, in the first of which is given an account of the organisations of the Science and Art Department and of the City and Guilds of London Institute; in the second, of the different classes of schools and institutions; and in the third, of the work done in special districts. It is illustrated with four coloured maps showing the distribution of the various agencies throughout the country. It concludes with an interesting summary, in which valuable suggestions are given, some of which we have often insisted upon. It points out, for instance, that, if the present movement for technical education is to end in the mere multiplication of science and art classes, farmed by incompetent teachers, dependent on grants for their livelihood, it may be that the resulting evil may outweigh the good. If the technical school of the future is to consist of an ill-assorted collection of such classes as are found by experiment to be the most "paying"—from the point of view, not of the education of the boy, but of the remuneration of the teacher, omitting all those harmonising studies which are "merely" educational and not grant-earning—the cause of secondary education will not be advanced, but rather thrown back by the change. What is wanted is more elasticity in method and more intelligence in teaching, and unless these results are achieved very little good can be done.

ELLIOTT'S "SMOKE ANNIHILATOR."

WE were enabled on Wednesday to be present at the trial of a new apparatus for getting rid of the smoke from the chimneys of factories, mansions, and other large buildings, patented by Mr. Samuel Elliott, of Newbury, the owner of the well-known wood moulding manufactory in that town. The "Smoke Annihilator," as it is christened, has now, we understand, been in operation for some weeks at Mr. Elliott's own works, where, according to all accounts, it appears to have been much needed, as the proprietor has been several times fined by the local authorities for creating a nuisance by allowing smoke to escape from the chimney of his boiler furnaces. Testimony as to the efficacy of the remedy applied was borne by no less authority than the Mayor of Newbury, who had himself been instrumental in fining the inventor, and, with other local magnates, was present at the trial. In our next issue we hope to illustrate and describe Mr. Elliott's apparatus; in the meantime, we may state that it appeared to successfully accomplish its purpose.

THE LINEFF ELECTRIC TRAMWAY.

WE had an opportunity of examining the Lineff electrical tramcar at Chiswick on the 25th inst. Mr. Lineff has dispensed with the slot in the roadway which was employed in his former system, and has modified the car and the track on which he experimented some two years ago to exhibit his electromagnetic system of completing the electric circuit. The conductor is laid in a closed conduit a few inches below the level of the road, and lying loose above it are a series of loose strips of galvanised iron. Iron rails, also galvanised, form the top of this conduit, and a powerful electromagnet carried beneath the car picks up these strips, and thus makes connection between the conductor and the rail. We propose to describe the method more fully next week.

THE WEYMERSCH BATTERY.

MESSRS. ALABASTER & GATEHOUSE have made a series of very exhaustive tests on the Weymersch battery. Forty-two cells were run on a batch of incandescent lamps, and thirty-six on an arc light, for 24 hours in each case. There were two $7\frac{1}{2}$in. square zinc plates to each cell, giving $7\frac{1}{4}$ amperes, and corresponding carbon and porous plates. One charge of the depolarising liquid lasted the whole 24 hours, and gave very constant electromotive force. There is very little local action on the zinc, and the cost of materials used is exceedingly small. Though only intended for use where steam power is not available, the Weymersch battery gives results almost comparable with steam engine and dynamo. As Messrs. Alabaster & Gatehouse have posed as enemies of the fraudulent primary battery, a favourable report from them may be taken to mean a great deal.

ELECTRIC LIGHTING AT BATH.

THE cause of electric lighting has been advanced a stage by the arrangements worked out in Bath. On Tuesday evening that historic city was the scene of a unique pageant. The occasion was the inauguration of the electric light, the outcome of a contract which Mr. H. G. Massingham had entered into with the Corporation to light the streets of Bath by electricity for seven years. By nine o'clock the dynamo room was filled with visitors from towns in the West of England and Wales. Precisely at nine o'clock the Mayor of Bath was led up to the Thomson-Houston machine, which was chafing its brushes and grinding its bearings in useless animation. He mounted the steps without any support, and with no outward manifestations of fear. For a moment, resolutely oblivious of the harrowing records of American experience, he seized the switch, and the blaze of light told that the current had done its work. After this the company went in procession through the streets to witness the novel effects. The visitors were able to observe subdued and bilious-looking gas jets down side streets, oil lamps in the tramcars, and candles with street artists on the pavement. Everything contributed to emphasise the contrast, and when, unexpectedly, as the party turned a corner, the moon itself "obliged," Mr. Massingham—who saw in it no possibilities in the way of a dividend—felt that his triumph was complete. On the conclusion of the street trip the guests were entertained at supper by Mr. Massingham in the Grand Pump Room Hotel, which was brilliantly illuminated by incandescent lamps. In the course of the supper a change of engine and dynamo was carried out without producing any appreciable effect on the lights in the hotel.

The business of installation was commenced early in the present year, and the incandescent lights in shops and private houses have been at work since March. The street lighting was inaugurated, as above described, last Tuesday. We hope to give a detailed description of this plant in a later issue.

REMARKS ON THE THEORY OF THE ELECTRIC WELDING PROCESS.

BY PROFESSOR OLIVER J. LODGE.

IN the current columns of the *Electrical Review* Mr. S. A. Varley has adduced an interesting little apparent difficulty in reconciling the doctrine that a rapidly alternating current flows mainly in the outer layers of a conductor with the fact utilised in electric welding that a bar gets thoroughly heated all through.

Now, first of all, we must remark that the thing being heated in the process of welding is not a single bar, but two bars pressed together end to end. Heat is thus primarily developed at the bad joint, no distribution of current other than one across the few points of contact being there possible. This amply accounts for the initial rise of temperature. As soon as the bars are softened by heat, no doubt they touch better, but by that time the temperature is so high that the portion near the joint is a very much worse conductor than the cold portions. Hence the heat continues to be localised where it began. But as soon as the joint is fairly good the whole can be regarded as a single bar with a peripheral distribution of current, and hence it may be thought that, although most of the heat must be generated at the already hot (and therefore highly resisting) place, yet the outside must get more heated than the inside. But remember that it is the great magnetic susceptibility which causes the extreme crowding of current into the skin of an iron bar. Taking its permeability for strong oscillating currents as about 6,000, the skin utilised for conduction in a non-magnetic substance like copper or zinc is 80 times as thick as it is for magnetic soft iron at the same frequency. Now, iron loses its permeability at a little above a red heat, and accordingly the laws of conduction through hot iron are the same as in a non-magnetic material. There is peripheral crowding, but it is not excessive.

But go a step further. Grant excessive peripheral crowding of current in the colder portion, does it follow that the outside will be hotter than the inside? By no means. The outside is subject to rapid air cooling; the inside is completely enclosed. So soon as the loss by cooling is equal to the rate at which heat is supplied in the outer skin, all inward gradient of temperature ceases: the whole section becomes exactly uniform. The next point to consider is the rate at which conduction is likely to equalise the temperature of a bar which is so rapidly supplied with heat in its outer skin as to maintain a falling gradient towards the centre. The heating of a current differs from the heating of a furnace, in that it is really generated inside the metal, instead of having to penetrate by radiation through a non-conducting film of gas and oxide, which, though truly excessively thin, yet constitutes a great obstruction. Heat is generated in the outer layer of the bar, and then flows by conductors into its interior, according to laws for which it is easy to write down equations, and at a pace of which it is not difficult to form a notion without any calculation. Notice that the central portion is but of small bulk, that it is subject to no cooling action, that it has not got to pass on the heat received to some other part of the rod; and then, even allowing that the material is not a good conductor, it will be perceived that an approximate equalisation of temperature from circumference to centre must occur very speedily—in far less time than the $\frac{1}{4}$ or $\frac{1}{2}$ minute during which the

Digitized by Google

bar is kept hot by the welder. If heat were generated at the centre of a bar or globe the gradient of temperature from within outwards, having to warm larger and larger volumes, would be both steep and permanent; but when heat is generated in the outer shell the gradient of temperature from without inwards is never steep and is only temporary.

Lastly, it may be convenient to point out that the hotter the joint locally is, the less heat will be developed in the cooler portions of the bar. This is a consequence of the law of electric induction. The bar forms a portion of a secondary loop round an alternating magnetic circuit, and is thus subjected to a given alternating e.m.f. equal to the rate at which the lines of magnetic force are cutting it. Under these circumstances the rate of production of heat in the bar is directly proportional to its total conductance. A secondary circuit of copper would be heated more rapidly than one of iron or lead. Anything which tends to diminish conductivity diminishes also the rate of heat production. At first the nature of the contact, and at last the hotness of the junction, has this effect: one or other cause keeps down the total conducting power of the welding circuit and causes less heat to be developed in it as a whole than might at first sight be supposed. But, as already said, the different sections of the bar will be heated just in proportion to their resistances, and hence whatever heat is developed is largely concentrated in the highly resisting already hot parts.

All these things are susceptible of being put quantitatively, and their statement makes an interesting problem. Meanwhile, perhaps, enough has been said to indicate that there is no real difficulty in reconciling theory with observation, because they have never really quarrelled. Moreover, it is plain that the considerations to which we have been led regarding the theory of the welding process are very favourable to the scientific character of that process as conducted by alternating currents.

THE BOARD OF TRADE AND ELECTRIC LIGHTING.*

(*Concluded from page 594.*)

Safety Regulations.—These were embodied in the old Orders, and were in great detail, such points as the distance apart of terminals, and the maximum current to be taken from any pair of terminals, being specified. The pressure on distributing mains and service lines was not to exceed 200 volts continuous or 100 alternating; and no portion of any electric line placed above ground, and not enclosed, was to be at a pressure from earth exceeding 200 volts. The St. Austell Licence of 1885 is, I think, the first licence or Order in which separate regulations have been issued; and the same form has been used in the Kensington and Knightsbridge Order of 1889 and the St. James's Licence of 1888, and nearly the same form in the Chelsea Order of 1886. These are more general in character. The limit of low pressure has been raised to 300 volts continuous, while alternating currents are not to be used except with the approval of the Board of Trade, and under such further regulations as may be considered necessary. A very important innovation has also been introduced in these regulations, providing that the undertakers shall cut off any consumer upon whose premises they find that a leakage exists having a resistance to earth of less than 5,000 ohms. This is to some extent a departure from the policy of the Board of Trade to leave the regulation of the circuits on private premises to the insurance companies; but, unfortunately, electricity does not conform to these arbitrary distinctions, and a bad leak on a consumer's premises is just as much a source of danger and difficulty as one on the main outside—in the case of direct supply systems at any rate.

The general regulations for overhead wires, made under section 4 of the Act of 1888, are pretty generally known at the present time, and I need not dwell upon them. As you are aware, they were thoroughly revised by your Council, who have also given their powerful assistance to the Board of Trade in the matter of some new proposed general regulations for undertakers of electrical supply, which, however, are still under discussion. The principal features of the new draft regulations are—(1) The division of the various systems of supply into three classes, viz., low pressure, high pressure, and extra high pressure: low pressure to extend to 300 volts continuous or 150 alternating; high pressure from above this to 3,000 volts, either continuous or alternating—that is, to as high a pressure as we have had practical experience of in distribution systems; extra high pressure, above 3,000 volts. (2) A general provision that where high-pressure conductors or apparatus are exposed in such positions as to be possibly touched by persons, or brought into contact with low-pressure conductors, they shall be entirely enclosed in strong metal casing efficiently connected to earth.

Supply Regulations.—These have been subjected to less alteration than the Safety Regulations. The variation of standard pressure permitted has been reduced, and in the new draft it is proposed, as already stated, to introduce the idea of a pressure to be declared at the consumer's terminals, which is not to vary more than 4 per cent., and the variation of which may be tested for the consumer on his application by the electric inspector. It is also proposed to take advantage of the powers of the transformer system and provide that the consumer supplied from a transformer on his premises shall have the choice of two pressures given him, one about half the other. No doubt many of the regulations that have been made are open to criticism; but I would point out that they are in every case the result of very careful consideration, and that observations on them from many different points of view have been submitted, and given, as far as possible, their due weight. It is not unlikely, therefore, that a criticism, even from a high electrical authority, may be unjust and erroneous, from the critic not being acquainted with all the circumstances and conditions which have guided the Board of Trade; and it should also be borne in mind that the Board are empowered to alter any regulations issued by them, or to repeal them and issue fresh ones, should the progress of electrical discovery and further experience make such a course desirable. And whatever imperfection may become apparent in these regulations, I can confidently affirm—and I feel sure that this proposition will receive the support of those among you who have experience of its methods of procedure—that the Board of Trade has been guided solely by the desire to do the duty imposed upon it by Parliament, and to serve the best interests of producers and consumers alike.

The Standardising Laboratory.—I should now like to say a few words about the standardising laboratory. You are probably aware that the Board of Trade have, in deference to the wishes of the large body now interested in practical applications of electricity, as expressed by a powerful deputation to the President last year, undertaken to provide something in the nature of a testing establishment for instruments intended for the measurement of electrical quantities, analogous to the Standards Department of the Board of Trade for weights and measures of the more gross and material quantities. They have also taken powers under the Weights and Measures Act of last Session to undertake such testing and verification, and to charge fees for it; so that these verifications, whatever their scientific value, will possess a legal value. A general scheme for the scope and working of this laboratory was drawn up very carefully last year by a committee of your Institution, in connection with which I should like to mention especially the hard work done by Dr. Fleming, in a cause which he has given abundant proof that he has at heart. The general idea embodied in this, in which I personally entirely concurred, is that the thing should grow from small beginnings. This, I think, is the English way, and I need only point to the present position of our own Institution as an example of its success. Our more impressionable neighbours on the other side of the Channel like to start these things in a different way. They must have something grand and striking, and of course there is much to be said for this view, if you have the means to carry it out; but it sometimes leads to, as it were, setting up a steam hammer to crack nuts. No doubt the steam hammer can do it very well, but a pair of nut-crackers is cheaper. Now I can promise that there will be nothing grandiose about our laboratory—we are starting with a very ordinary pair of nut-crackers. It is hardly necessary to observe that the small beginnings idea was the part of the scheme most to the taste of the Treasury; in fact, to use an electrical metaphor, my Lords would have liked our electric particle to have acquired its potential of doing work by starting in the legitimate way at an indefinite distance from the charged body (the national purse), and to have been a long time on the road too. However, let us not forget that if we are electricians we are also taxpayers? Now what we hope to do in this laboratory is, first of all, to get the true values of the electrical units, within a very small possible percentage of error. We are not tied to the so-called legal units, which I may remark have no legal value in England; but with the assistance of Lord Rayleigh and the Standardising Committee of the British Association we hope to get even nearer the truth than was arrived at with this set of units. Secondly, having got there, we hope to keep there by well-devised checks and frequent reference to the fundamental measurement. This, as we are at present advised, will be the measurement of current by the quantity of silver deposited from solution in a determined time. Thirdly, so soon as we are satisfied that sufficient accuracy and permanence has been arrived at with our instruments and methods, we shall be ready to receive instruments, either for simple verification in the case of ordinary commercial instruments, at a small charge for each reading, or for thorough testing and certification in the case of instruments submitted as sub-standards. The rules and charges have not yet been drawn up, but it is probable that instruments will be required to be marked with a clear and intelligible scale—whether of degrees, or volts, or amperes, is quite immaterial; the extreme range of the instrument must be given approximately and whether it is intended for alternating or continuous currents or pressure, or for both. The reading given by the instrument on its own scale for each current or pressure asked for will be taken, probably, in all cases both with increasing and with decreasing readings. No extreme accuracy will be guaranteed for these readings, but it is hoped not to exceed an error of ½ per cent. from the true value. Of course, in the case of ordinary commercial instruments, we should give no sort of guarantee that the instrument will remain constant for any time, or under different conditions. Sub-standards will be subjected to long and rigorous testing, including the determination of their variation under different temperature and the permanence of their constants. I am afraid, however, that in most cases there will be some difficulty in giving any guarantee of the constancy of an instrument after it has passed out of our hands. The power for laboratory purposes will be supplied from two batteries of accumulators—one of four very large cells simply to give steady continuous currents up to 2,000 amperes; the other, consisting at first of 100 smaller cells, will be used directly for continuous pressures up to 200 volts, and also to run the machinery. The machinery referred to is two pairs of dynamos, one of each pair being energised by the cells as a motor and driving the one connected to it as a generator. One of these generators will be an alternate-current machine, and the other a high-pressure continuous-current machine. In connection with the alternate-current machine we shall have a set of transformers. In this way we hope to get currents practically as steady as if taken direct from the accumulators, and in the case of alternating currents and pressures any frequency within the limits of practice. The limits we propose to work up to at first are:—Continuous current, 2,000 amperes; continuous pressure, 2,000 volts; alternating current, 500 amperes; alternating pressure, 2,000 volts. The building and alterations necessitated are now nearing completion, and we hope to have the laboratory in working order in about two months' time.

* Paper read by Major Cardew before the Institution of Electrical Engineers on the 17th ult.

THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

(*From our New York Correspondent.*)

(*Concluded from page 595.*)

In his "Note on a New Photometer," Dr. Edward L. Nichols said that methods of photometry which take no cognisance of quality were ill adapted to the study of sources of light which differ widely in temperature, and his instrument has been devised to determine both the character and intensity of an illuminant. Existing types of the spectrophotometer could be made to give good results, but they are expensive and difficult to use. The new "horizontal slit" photometer is really a spectrophotometer in which the polarising device is dispensed with. In it the simple principle of the Bunsen photometer is applied successively to the various regions of the visible spectra of the source of light which are to be compared. A direct vision spectroscope of Browning's form is attached to the usual bar of a Bunsen photometer from which the disc and mirrors have been removed. The optical axis of the collimator is horizontal and at right angles to the photometer bar. The slit is horizontal, and lies in a straight line joining the sources of light set up in the usual manner at the ends of the bar, which is of considerable length, in this case 500 c.m., and should be divided into thousandths. In front of the spectroscope slit are two right-angled prisms of equal size and of the same glass. Their vertical adjacent edges bisect the slit, and light travelling from either end of the photometer bar is totally reflected by them, entering the right and left hand end of the slit in a direction parallel to the optical axis of the collimator tube. The two sets of rays are vertically dispersed by the prisms, and appear in the field of view as two vertical spectra standing side by side. Equal wave lengths are in the same horizontal line, and any desired region may be brought into the centre of the field by an angular movement of the ocular telescope. The telescope moves along the arc of a suitably divided semicircle, to which it may be clamped. Wave lengths, corresponding to the various circle settings, are determined once for all by observation of the more prominent of the Fraunhofer lines. When the instrument is placed at the middle of the photometer bar between lamps identical in intensity and quality, the two spectra are of equal brightness throughout, wave length for wave length, from red to violet. If the two lamps differ in intensity but not in quality, the two spectra will differ in brightness by the same amount from end to end, and a position may be found upon the bar for which they will be identical throughout. Under these circumstances the instrument may be used as a simple photometer, the setting for any wave length whatever giving the candle-power. For the comparison of lights of similar character, the instrument offers certain manifest advantages over the various forms of the Bunsen photometer. Various measurements were presented by the author proving the merits of the instrument.

"Magnetic Data of the Sprague Street Car Motor" was the title of a paper by Mr. H. F. Parshall.

At the opening of the afternoon session, the newly elected President, Professor W. A. Anthony, took the chair, and a paper was read by Mr. Oscar T. Crosby, on "The Limitations of Steam and Electricity in Transportation." The author began by stating these propositions: That it is possible to construct motors capable of doing the required work in transportation; that it is possible to continuously generate electric energy equal to the capacity of any number of such motors; at any desired loss, and any desired distance, it is possible to supply by running contact the necessary current at considerable pressure for the working of such motors. He had seen 75 amperes at 500 volts continuously supplied to a car moving at over 110 miles per hour. With these premises established, the discussion resolved itself into three parts—first, the possibility, without reference to economy, of steam and electric propulsion under given conditions; second, as to the relative cost; and third, as to the relative amount of power required, the comparison being made with the direct application of steam power on the tracks. It was his experience that the adhesion coefficient was not increased to any practical degree by the passage of current from wheel to rail. Since January 1st, 1890, a speed of 86 miles per hour in England and 87 miles per hour in America had been reported. So far as steam supply was concerned, he believed it possible to attain a speed of 150 miles per hour. The train resistance is due to motion through the air, to friction and blows between vehicle and track, and between different parts of the vehicle. He had found that at 100 miles per hour the air pressure was 13lb. to the square foot, which, by proper shaping of the front, could be reduced to 6½lb. The tonnage resistance on a first-class track with good rolling stock was 20lb.

Digitized by Google

per ton, at 125 to 150 miles per hour. With 20 per cent. loss, electricity becomes cheaper than steam at about 70 miles per hour; while at 40 per cent. loss, which is about the lowest with electric propulsion at present, electricity becomes more economical than steam only at 140 miles per hour. The general conclusions arrived at were that—(1) A slow-speed armature on the axle would place the electric motor in the lead at all service speeds. (2) Above 70 miles per hour an electric motor of 90 per cent. efficiency, with gearing of 90 per cent. efficiency, would prove more economical than steam, excepting for infrequent service on long lines. (3) For heavy traffic steam would be more economical up to 100 miles per hour, if the electric motor and the gearing had a combined efficiency as low as 60 per cent. (4) At 100 miles per hour and upwards, neither steam at 90 per cent., nor electric apparatus at 60 per cent. efficiency, is commercially practicable. (5) The economy of electricity through the stationary engine will depend upon the cost of coal. (6) Bad roadways, and large areas exposed to atmospheric influence, as in street railway work, reduce the speed at which electric motors of any efficiency become cheaper than steam. (7) With small locomotive units the electric motor loses less relatively of its advantage. (8) Multiplying the number of motors should be avoided as far possible. (9) Cleanliness and compactness of electric machinery may be of great value in special cases. The possibility of returning to line the energy now wasted in brakes may be of value. Loss due to low efficiency in starting can scarcely be avoided either in steam or electric engines.

The paper by Mr. Hermann Lemp, on "Automatic Electric Welding Machines," was accompanied by practical demonstrations of the working of the apparatus, and was listened to with great interest. The ordinary welding process, he said, required the greatest skill of the smith in heating the metals to the proper temperature at the right spot, and preventing the accumulation of scale. While skill may be successful with metals of high melting points and low heat conductivity, easily fusible metals, and especially good conductors, baffle all attempts as long as an exterior heating source is employed. The electric process has made it possible for less skilled operators to make good welds, and has created an art equally adaptable to all metals and combinations of metals. Sixty-seven metals, alloys, and combinations were named as having been successfully welded, among them wrought and cast copper, lead, tin, zinc, aluminium, silver, platinum, gold, magnesium, steel castings, tool steel, Bessemer steel, cast brass, type metal, German silver, fuse metal, &c. Among the combinations were copper to brass, wrought iron, and German silver, wrought iron to brass, steel, and German silver, tin to lead, &c. The inventor was not satisfied with this advance over ordinary welding methods, but laboured with the problem of producing a machine in which all conditions for successful operations were mechanically controlled to attain uniform results, combined with rapidity, and requiring little attention. This led to the invention of the automatic welding machine, which has proved to be of special importance in connection with easily fused metals, leading to the successful welding of aluminium, silicon, and aluminium bronze, which, even with the electric process, requires considerable skill. Electric welding has been accomplished with continuous and alternating currents; secondary batteries and unipolar machines may and have been used. In certain locations it may be desirable to use the continuous current, but the alternating has been found best adapted by reason of its more economical production at low e.m.f. and large volume. There is, however, another advantage, arising from the fact that self-induction assists materially in heating the exterior of the bar to be welded, thus compensating for the loss by radiation which is apparent in the continuous current process. Two methods of distribution are in use, the direct and indirect. In the former an alternating dynamo is used, having two windings on the armature, one of which furnishes currents rendered continuous by a commutator to excite the field magnets, and is controlled by switch and rheostat; the other, consisting of a single turn of heavy copper cable, furnishes the welding current, which is led through collector and brushes to movable copper clamps arranged to receive and guide the welding objects during the operation. In other forms the field magnet is the movable part, in which case no heavy currents have to be carried through the collector and brushes. No direct welders are built at present for currents above 4,000 amperes. The indirect method of distribution is now almost exclusively used. In its simplest form it consists of one alternating dynamo, self or separately excited, and one welder, which is a transformer, with the necessary clamping and operating appliances. The self-exciting dynamos used are from 1,000 to 20,000 watts output, and may be regulated by means of a reactive coil to give a varying e.m.f. never to exceed 300 volts. The perfection of the work is influenced by the projection of the abutted pieces in the path of the current; the e.m.f. of the welding current; the end pressure applied to force the abutting ends into each other at welding heat; and the interruption of the current at the proper time.

The projection of the abutted pieces varies with their diameter. For copper a projection twice the diameter gives the most economical results, while with steel and iron the projection equals the diameter. For a large class of work, carriage hardware for instance, the surfaces coming in contact have a light scale which must be removed by grinding, or overcome by the e.m.f. of the current. In many cases the cleaning is found more expensive than the extra power to force through the scale. For uniform results the end pressure is found to be the most important factor. It varies with the materials, being approximately 1,800lb. per square inch for steel, 1,200lb. for iron, and 600lb. for copper. The interruption of the current at the completion of the weld is important for all easily fused metals, otherwise a large portion of the conductor on either side as well as the weld itself will be melted and torn asunder before any pressure device could follow and bridge the gap.

THE DEPTFORD CENTRAL ELECTRIC LIGHTING STATION.

The Deptford Station is, as is well known, anything but completed, as far as erection of the plant goes, but in one sense it may be said to have been complete before it was begun, because every detail was planned out with the greatest care and forethought before the actual work was commenced, and a description of this station now will probably give a fairly exact idea of what the finished station will be like, and will be more interesting to our readers, as the Deptford scheme is exciting so much attention at present.

We have already published accounts of the work at Deptford, and may refer the reader to our issues of the 26th October, 1888, and 19th July, 1889. As we have already said, the designs have not been altered since the station was begun, so it is unnecessary to repeat the general description.

The visitor on entering the building is struck with its enormous size. At first one is lost in admiration of the pluck and enterprise shown in setting up business on such a scale, but the feeling is soon qualified by an uneasiness as to whether the pecuniary risk is not unnecessarily great in proportion.

The present position of the Corporation as regards mains may be stated. They have made and put down a mile or so of their own mains, but they are not in use. They have, therefore, to depend on the Fowler-Waring concentric mains. These are too small, and with the load now in use the loss over them amounts to over 1,200 volts. The outer conductor is only lightly insulated, and would not stand this, and the leakage all along the line from it to earth has given considerable trouble to the telephone companies. The Corporation has therefore been obliged to use only the inner conductors of the cables, leaving the outer conductors idle. The action on the telephones due to the use of separate cables is avoided by crossing the leads frequently. Transformers have also been inserted at Deptford to get rid of the earth in the primary circuit.

One engine and dynamo is now doing the Grosvenor Gallery work, and another engine and dynamo are ready for work. The cables now in use are Siemens' concentric for distributing mains at 2,400 volts, and Fowler-Waring for temporary trunk mains. The Ferranti concentric mains are being made, and about a mile has been put down, but they are not in general use yet. They have been officially and otherwise tested, by cutting through the outer insulation with a pick-axe until the outer conducting tube is exposed. It may be safely grasped in the hand, as might be expected. The joints are long cones, so that any leakage would have to pass along a considerable distance to get to the other conductor. No doubt the ozokerit will really unite perfectly. In fact, ozokerit has, we believe, properties analogous to pure rubber, in the facility with which it will unite under pressure. A little warmth would certainly unite it. In this point vulcanised rubber is inferior. It will never repair a leak in its substance, whereas pure rubber, and probably ozokerit, will.

As there is little new to describe, we may devote some space to a critical discussion of the Deptford scheme; not with the object of giving the London Electric Supply Corporation good advice, as we do not know that it has any need of it, but because the success or failure of the Deptford scheme is a matter which concerns not only the Corporation itself, but also, and that perhaps to an even greater pecuniary extent, the whole electric light industry in the kingdom, and, to a considerable degree, even abroad. A great deal of the criticism with which the Deptford scheme has met has been biassed by rival interests. We do not mean that anything unfair has been said, but it is not possible for engineers who are throwing their whole energies into direct current work to be quite unbiassed in discussing alternate distribution. The London Electric Supply Corporation's Provisional Order also came first at the recent Board of Trade inquiry, and the Corporation had thus not only to defend its own particular system, but had to bear the whole brunt of the battle waged against alternating current system in general.

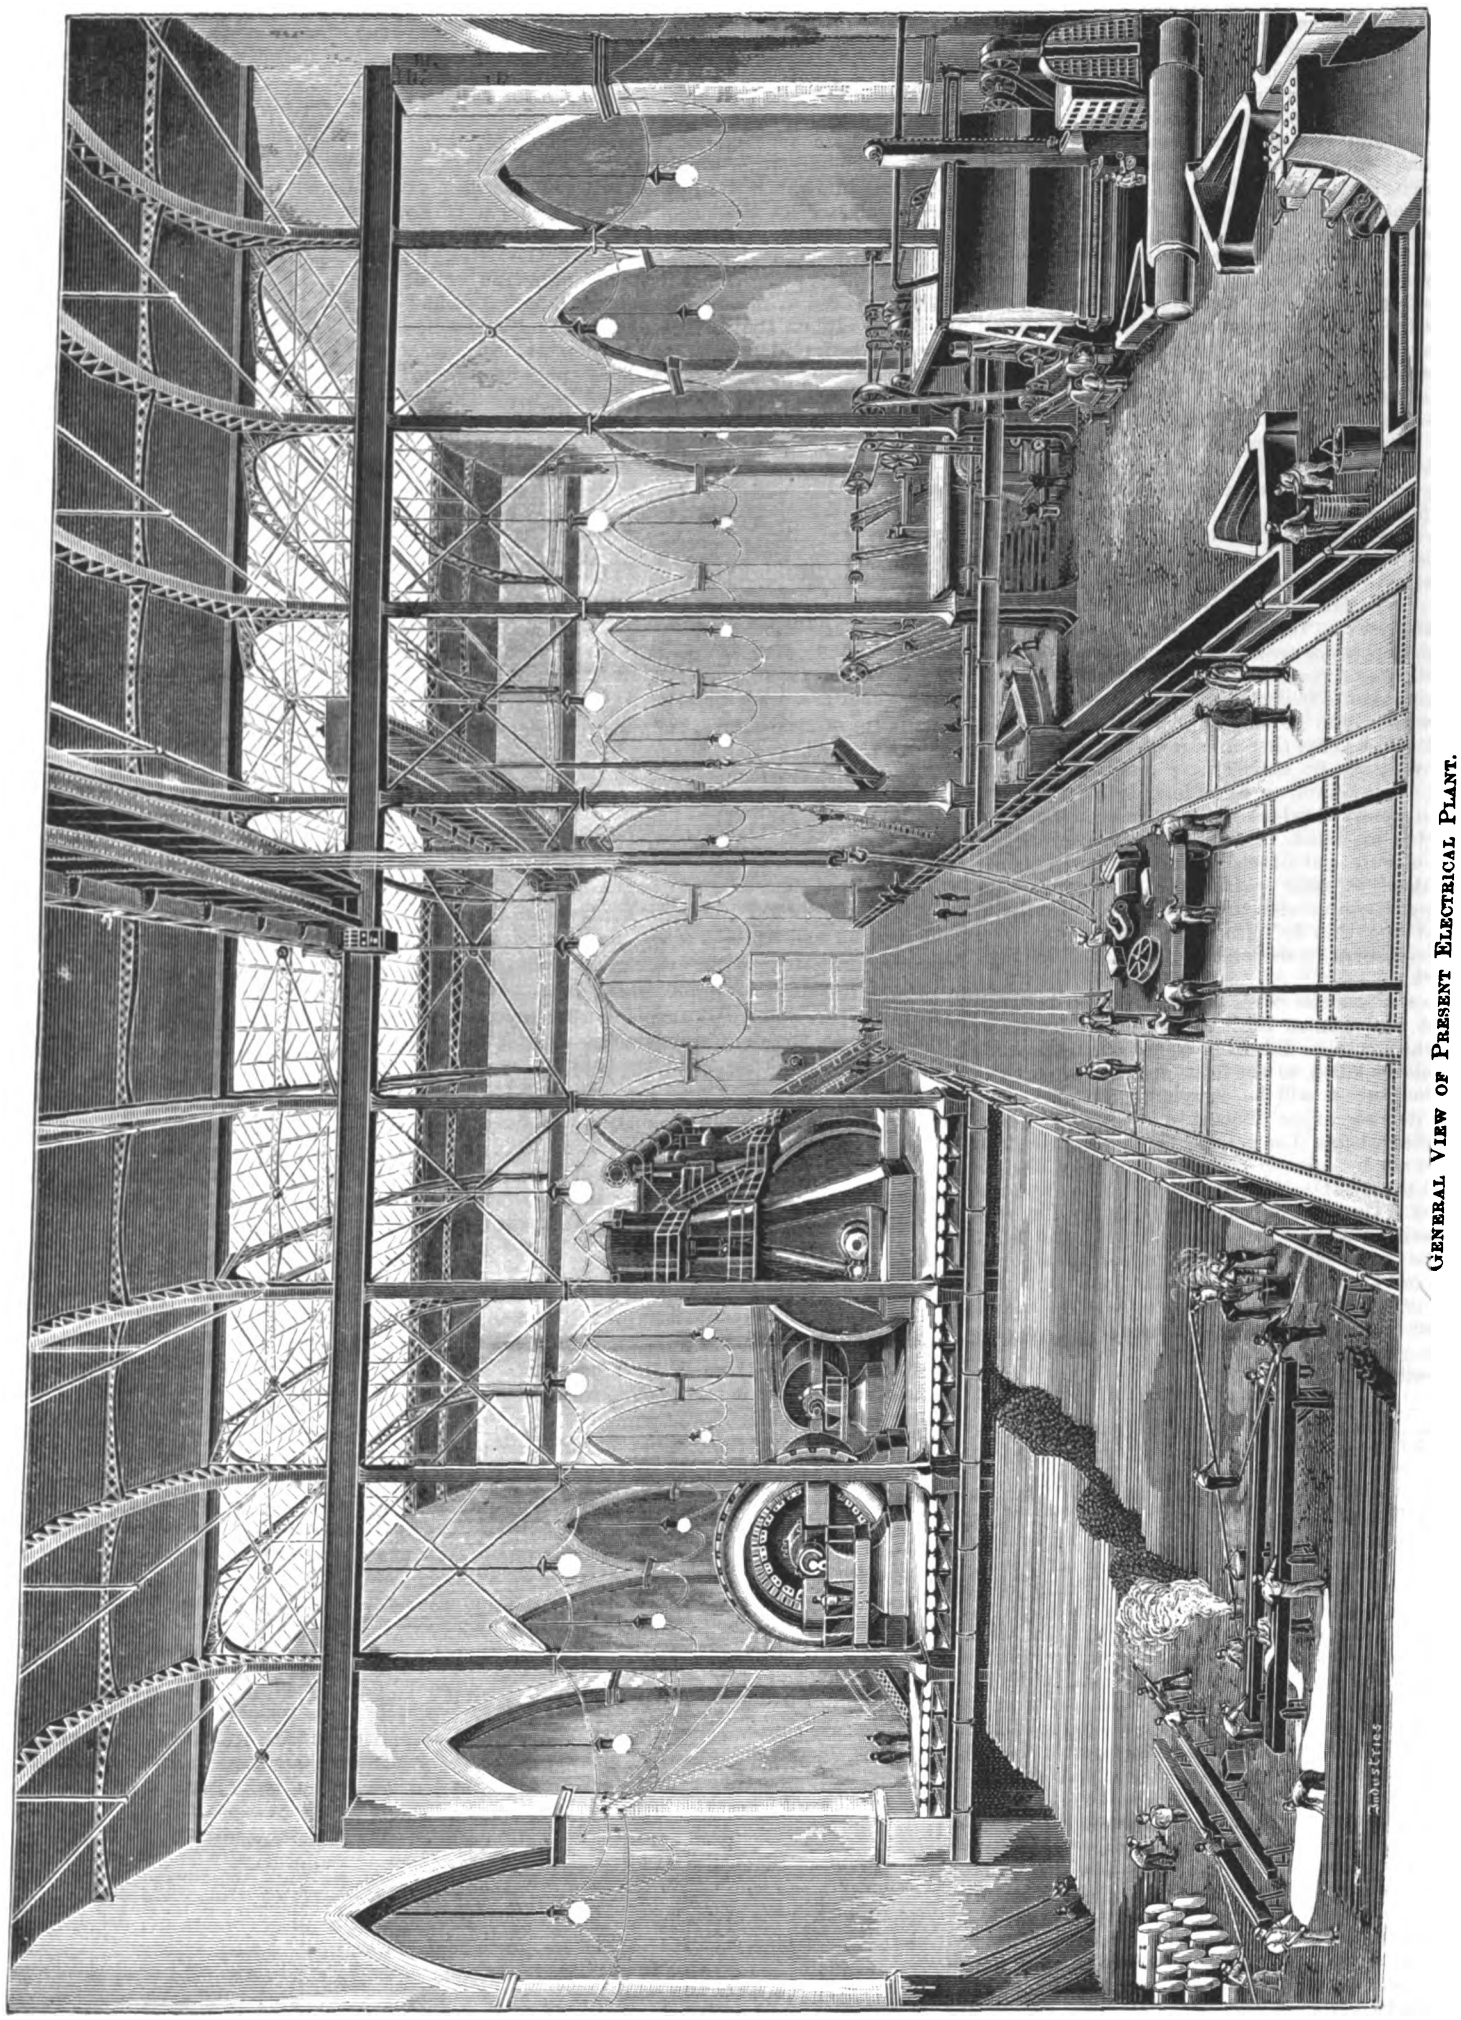
It has been said over and over again that the Deptford scheme is a wild experiment, and is more or less certain to end in a dismal failure which will do incalculable harm to the industry generally. The first novelty is transmitting electrical energy at 10,000 volts. This is simply a question of insulation, but that is no small matter. The whole question of insulation for very high electromotive forces is very obscure. It would seem quite likely that it is not a question of the maximum difference of potential between the two leads—in this case two concentric tubes—but of the rate of fall of potential; that is to say, the difference of potential between the faces of each little element of insulation. For instance, we can easily imagine that indiarubber will stand a stress of say 1,000 volts per millimetre, so that a large sheet one centimetre thick would stand 10,000 volts. In this case all the portions of the rubber have to stand equal stresses. But if the rubber is wrapped round a cylindrical conductor, the inner layers will be subjected to a greater stress than the outer; and if the stress is near the maximum, thickening the coating of insulation can do little good. The rate of fall of potential depends on the diameter of the cylinder, so that the larger the conductor the easier it is to insulate it so as not to break down. On the other hand, the larger the conductor the lower the insulation resistance measured in megohm miles, so that we have the paradox that a small conductor which shows a high insulation resistance may be more likely to break down than a large one with a comparatively low insulation resistance taken in megohm miles.

Then, again, there is the question of insulation conductivity; it may or may not follow that a material which conducts slightly is likely to break down. It is most probable that a dielectric breaks down suddenly, and that a microscopic conduction has nothing to do with this. If that is the case, insulation resistance measurements give no indication as to safety against breakdowns, except in so far as they localise an incipient fault.

These speculations may be considered somewhat crude and unsatisfactory. They are brought forward, however, merely as suggestions, as it does not seem as if these questions had ever been studied. We may find that a material which does not easily develop local faults, and is therefore best for telegraphic purposes, is apt to break down suddenly under a high electromotive force on account of a totally different order of properties. We may also find tubular conductors more easily insulated than solid rods of same cross-section.

Returning to the Deptford trunk mains, there seems to be no reason why 10,000 volts is not practicable, especially with a conductor an inch in diameter; but great difficulty may be expected in the joints, even when coned, and especially if expansion and contraction has any chance of "working" the joints. We would again suggest that the difficulty may, perhaps, not be in making the joint to give a high insulation resistance, but in arranging it so that the fall of potential over the insulation is always gradual. The problem is, in fact, analogous to designing a static electric machine so that it has no corners to form discharge points. Ozokerit is tougher and more elastic than paraffin wax, and does not seem to develop minute cracks on solidifying.

It must be borne in mind that even if the mains should prove incapable of standing 10,000 volts, which seems hardly likely, the only result will be increased capital expenditure for working at 5,000. The cost of leads would, of course, be serious, and the Corporation shareholders will have lost some money from their capital account, but it will make no difference to the public at large. The money will simply be written off; competition will prevent its interest being charged on the consumers. The lead question is, then, not so important from our point of view as might at first sight appear.



Some trouble has already arisen from the action of the alternate current on the various telephone circuits with the temporary mains as already mentioned. Another difficulty may be expected with the permanent mains, with one end earthed, and at first sight it appears very serious. There are, however, several ways of arranging such circuits, so as to have neither leakage effects nor inductive influence on the telephones.

The enormous size of the dynamos has caused a great deal of comment. In one way the dynamos are experimental, as nothing of anything like the proportions has ever been made before. In making a very large dynamo after experience confined to small ones, there are two

THE DEPTFORD CENTRAL ELECTRIC LIGHTING STATION.

(For description see opposite page.)

General View of Present Electrical Plant.

Digitized by Google

ways a designer is likely to come to grief. The purely electrical part of the calculations are as accurate when applied to a large, as to a small machine. The mechanical stresses can be got out with equal certainty. But there is uncertainty about Foucault currents which generally cannot be even approximately estimated, because of the irregularity of the masses in which they are induced; and there is still greater uncertainty about ventilation. In Mr. Ferranti's large machines, however, the pole pieces, and the armature conductors themselves, are small—in fact, much smaller than in many machines which have already been made—so there is no room for errors as regards Foucault currents, and the machine is so proportioned that there is no chance of the armature heating at full load. In fact, alternate machines with strip armatures are always limited as to output by the mechanical strength of the armature, or the drop of electromotive force due to armature reactions, and not by the heating of the armature. The size of the dynamos and the general design of the station unfortunately gives trouble as to running in parallel. The large dynamos would, of course, have some tendency to keep in step, but whether they can be commercially run in parallel is another matter. The introduction of the high electromotive force into the dynamos, though it saves some expense, demands special insulation. Though this has been carried out very thoroughly, it would have been simpler to have made it unnecessary by transforming up. The pole pieces have to be covered in with ebonite caps.

The use of ebonite for protecting the pole pieces seems a little risky. Ten thousand volts is probably quite enough to produce ozone. Ozone acts very readily on indiarubber, and it seems likely that the ebonite, which contains about 50 per cent. of sulphur, will soon be coated with a film of sulphurous, and perhaps sulphonic, acid. Not only, therefore, may the ebonite be itself destroyed, but its surface may gradually become conductive. This action, or something similar, has, we believe, been observed where ebonite has been used for statical electric machines. Perhaps some varnish might protect the ebonite, but linseed oil is acted on by ozone, and copal itself is easily oxidisable. Perhaps a thin coating of pyroxylin varnish, thick enough to protect the ebonite, but too thin to burn easily, might do. The question may be of considerable importance in high tension work.

Mr. Edison's "quarter of an inch of ebonite between the current and human life" is, we think, nonsense, because if the armature did short circuit on to the fields no one would be killed, as the fields are already earthed.

When the station will be completely at work on a large scale it is somewhat difficult to say. It has been remarked that when a man reaches fifty he realises that things take much longer than is expected. But there is little doubt that the Deptford Station will, in the long run, be a success. The work is engineered by Mr. Ferranti, with the assistance of his partner, Mr. Sparks, and of Mr. Kolle. The Corporation also owes much to the vigorous policy of Lord Crawford. If there is any one who, with practical commonsense, careful forethought as to minutest details, and thorough knowledge of his subject, can successfully begin and complete this work, we believe it is Mr. Ferranti.

THE CHEMICAL SOCIETY.

On the 19th inst., at the last meeting of the Chemical Society for the session, a paper was read by Mr. Mond, who, in conjunction with Drs. Langer and Quincke, has studied the "Action of Carbonic Oxide on Nickel." When carbonic oxide is passed over the heated nickel it is absorbed with the formation of a black powder containing 11 per cent. of nickel, of which the whole cannot be removed by acids. A small quantity of nickel appears to be able to decompose an almost unlimited amount of carbonic oxide. There has also been obtained a colourless volatile liquid containing nickel, the composition of which corresponds to the formula $Ni(CO)_4$. This remarkable substance has a specific gravity of 1·3185 at 17° C., and boils at 43° C.; it is soluble in alcohol, benzene, and chloroform, and is not acted on by dilute acids and alkalies. At 60° C. its vapour explodes. Its vapour density at 50° C., determined by Victor Meyer's method, is 6·01, instead of 5·9, the number demanded by theory, a fact of special interest, as this is the first substance from which it has been possible to determine the vapour density of nickel. This value corresponds to an atomic weight of 58. The nickel obtained from it has been deposited as a mirror on glass tubes, and proved to be exceptionally pure. This affords an excellent source of the metal for the determination of its atomic weight, which was done, the values obtained being 58·58 and 58·64, as against 58·52, the generally accepted number. From this it is plain that the nickel which we have been accustomed to regard as pure is really so; and that the statements of Kruss and Schmidt to the effect that nickel, hitherto thought to be an element, actually contains two bodies —(1) true nickel, and (2) a new element (*gnomium*)— are due to misconception.

In the discussion which followed, Professor Ramsay commented on the extraordinary fact that a compound of nickel of this description should be *colourless*. Mr. Howard pointed out that a knowledge of such a substance might furnish a key to the action of carbonic oxide in many metallurgical operations, too often obscured by the convenient term "catalysis." Mr. Page reminded the meeting of the compound of carbonic oxide with potassium which was formed in the preparation of that metal, and its similarity to this substance in its explosive tendency. The structure of such a body was fraught with interest. The president (Dr. Russell) inquired whether the freedom of the nickel from cobalt had been proved by means of the spectroscope, to which Mr. Mond replied that it had not, but its absence had been demonstrated by the ordinary tests. It was a remarkable thing that no similar body could be obtained from cobalt, and, in fact, a method of separation might possibly be based on this fact.

Notes.

PHOSPHATES IN ALGERIA.

Deposits of phosphate of lime have been discovered in the West of Oran, but the distance from the sea is great, and there are no good roads. It is therefore unlikely that they will be turned to good account for a good many years yet. There are other deposits near Souk Ahras, in the department of Constantine, but these have not been much utilised hitherto, as the colonists have not yet learnt the value of chemical manures.

TEXTILES IN ROUMANIA.

Consul-General Sanderson, of Galatz, reports that cotton twist is almost entirely imported from England, and that the most of the T-cloths and shirtings are also English; but German and Swiss productions are gradually ousting Manchester cotton prints. Of lighter goods the bulk is obtained from Germany and Switzerland. Sacking and jute carpets are still in large demand from Great Britain. In woollen goods Bradford maintains its position; the chief opposition is from Germany. The nearest suppliers have a considerable advantage over us, owing to their being able to meet a change of demand or fashion more rapidly and having cheaper transport. Austria, for example, has a great advantage, and both the Germans and Austrians establish branch houses in Roumania, while we have only an occasional agent. English circulars are of little use.

PUBLIC WORKS IN FRANCE.

From Consular reports from the Boulogne and Calais district we learn that the virtual completion of the new harbour and large floating dock at Calais has not yet attracted trade to the port. The floating dock is completed, as are also the warehouses, hydraulic cranes, apparatus for lighting with electricity, lines of rails, &c.; all that is wanting now are ships to fill it; these have not yet arrived. So far, it has only afforded accommodation to the few vessels which formerly used the old floating dock; this latter will continue to be used for vessels with petroleum, as also for small vessels. The dry dock is not yet ready for use, the caissons and pumping machinery not being completed. Quays have been levelled, roads made, bridges built over the new canals and lines of rail—indeed, an immense amount of work has been done, and very thoroughly too, but there are many things still to be completed; for instance, the entrance from the old tidal harbour has to be rounded off, and the old and new quays united. A scheme was started some time ago to improve Boulogne Harbour, but beyond some dredging little has been done.

RAMIE CULTIVATION IN ALGERIA.

Great hopes have been founded in Algeria on the successful cultivation of the ramie. This subject has engaged the attention both of the cultivator and the manufacturer, but it cannot be said that from their united point of view the question has been definitely settled. There appears to be no great difficulty about the cultivation of the plant. Experiments have been made at Algiers, Boufarik, Staoueli, Bône, Perrégaux, and St. Denis du Sig, and wherever it has been planted it has succeeded—at least, in land capable of irrigation—and it has yielded three and sometimes four "cuts" per annum. The first year is devoted to planting and preparing the soil, without any return; the second may be expected to yield half a crop: the third, three-quarters; and by the fourth it should be in full bearing. It is planted out in rows 50 centimetres apart, and at distances of 25 centimetres from each other in the lines, thus giving 80,000 plants per hectare. In the fourth year the plant is expected to produce twelve useful shoots, each of which will weigh about 12 grammes. Allowing four "cuts" per annum, and 75 per cent. for loss after drying and cleaning, there should be produced in the fourth year 46,000 kilogs. of stalks, yielding 11,500 kilogs. of fibre. One hectare, therefore, should produce: First year, nil; second year, 5,752 kilogs.; third year, 8,625 kilogs.; fourth year, 11,500 kilogs. The fibre will cost the producer 10fr. per 100 kilogs.; add to this 8fr. per 100 kilogs. for decortication, 7fr. for transport, and we have a total cost of 25fr. per 100 kilogs. for the cleaned fibre, landed at its destination. It is stated that this produce will never fail to command a price of 35fr. per 100 kilogs., so that the cultivator may expect a profit of 10fr. per 100 kilogs., or 1,150fr. per hectare, a return which can hardly be expected from any other kind of culture—even that of the vine.

TELEPHONES AND ELECTRIC TRAMWAYS.

The Telephone Company and the Weston-super-Mare Tramway Company had a skirmish before a Select Committee of the House of Commons last week. The Tramway Company had Messrs. Taylor and Graham, and Messrs Pember, Moulton, and Pollock appeared for the Telephone Company. The Telephone Company applied for a clause to bind the Tramway Company not to disturb existing or future telephone lines. The Tramway Company objected to this, as it would necessitate an insulated return, instead of the rails. They offered to put up metallic returns to the existing telephone circuits if the Telephone Company agreed to do so in erecting future lines. The Telephone Company wanted to continue their use of the earth return in existing lines, and to secure it for future lines without disturbance. The Tramway Company called Mr. S. Sellon, their engineer, who gave evidence as to the cost of insulated returns for tramways and telephones, and Mr. J. Swinburne, who gave electrical evidence. The Telephone Company called Sir W. Thomson, who held that it was not fair for the Telephone Company to be debarred from free use of the earth return in future. Sir Frederick Bramwell and Dr. Hopkinson were ready to corroborate his evidence, but the Committee discouraged further testimony. The Committee finally inserted a clause whose meaning is enigmatical. Apparently they have been not only eager to prevent the telephones being disturbed by the tramways; but they have also taken measures to guard the tramways from being disorganised by the intrusion of telephone currents. It is to be earnestly hoped that this Bill may come before a strong Committee in the House of Lords, so that a clause doing justice to both sides can be inserted which may become a good precedent. The matter is of enormous importance to tramway and telephone companies.

PREPARATION OF PICRIC ACID.

A process has recently been patented in Germany for the production of picric acid from crude phenol. It is based upon the following observations:—(1) Phenolsulphonic acids are much more easily nitrated than phenol itself. (2) The sulphonic acids of crystalline phenol are more readily formed than the corresponding compounds of cresol, &c. (3) The uncrystallisable constituents of crude phenol may be first nitrated and then removed, (*a*) by the use of the calculated quantity of acid, (*b*) by regulating the temperature. The residual pure phenol is then nitrated and treated in the usual manner. Following on the above observations two processes have been worked out. In the first, the crude phenol is treated with a quantity of sulphuric acid equivalent to the crystallised phenol present; the resulting sulphonic acid is dissolved in water, and decanted from oily impurities, and the solution treated with nitric acid. Should any cresol be present it will be unattacked, and may be separated by treating the picric acid with sulphuric acid, and afterwards washing with water. In the second process the crude phenol is treated with a large excess of sulphuric acid. The sulphonic acids are dissolved in water, and treated with sufficient nitric acid to nitrate the cresol compounds. On cooling, the nitro-cresol separates as an oil, and may be removed. This process may be varied by treating the mixed sulphonic acids with an excess of nitric acid. If the resulting compounds be then treated at 90°–100° C. with water containing 12 per cent. sulphuric acid, the trinitrocresol will separate as an oil from the picric acid.

Patent Record.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

9th June, 1890.

8864. Breakell, T. ..... Grinding machinery.
8865. Jones, B. ..... Buffers.
8866. Hepenstal, G. ..... Wheel tyres.
8867. Beardmore, W. ..... Armour plates.
8870. Haigh, W. C. ..... Washing machines.
8873. Daw & Daw ..... Valves for rock drills and pumps.
8877. Rollinson, T. ..... Looms.
8885. Woodville, G. ..... Brakes.
8887. Abercrombie, D. ..... Adjusting bearings.
8903. Barraclough, F. ..... Flying machines.
8904. Krell, O. ..... Hydraulic lifts.
8906. Jenin, O. ..... Propulsion of vessels.
8909. Woodall, H. ..... Charging gas retorts.
8910. Heathorn, T. B. ..... Steering and propelling boats.
8913. Wells & Cunnington... Hot air engines.
8918. Tellier, C. ..... Production of motive power.

10th June, 1890.

8924. Cockroft & Farmer ... Sewing machines.
8925. Allison, H. J. ..... Refrigerating apparatus (*Wood*).
8926. De Castilho, S. A. ..... Boat releasing gear.
8930. D'Iszoro, L. S. ..... Charging gas retorts.
8937. Poole, G. A. ..... Steam engines.
8940. Ashlin, H. C. ..... Oil-carrying vessels.
8947. Thompson, W. P. ..... Utilising wave power (*Doire & Rifenburg*).
8948. Everson, G. H. ..... Cold rolling tubes.
8949. Oemler, G. L. (of the Firm of Leipziger Strikmaschinen Fabrik) ..... Knitting machines.
8952. King, J. T. ..... Hot blast stoves (*Kennedy*).
8954. Harrop, J. ..... Furnaces for heating metal bars.
8961. Thorpe, R. H. ..... Regulating hydraulic power.
8963. Taylor, W. H. O. ..... Valve gear.
8969. Lindsey, C. C. ..... Cloth-cutting machine.
8972. Schermerhorn, G. W.... Folding boats.
8974. Newton, H. E. ..... Printing machinery (*Hoe & Co.*).
8975. Timmis, I. A. ..... Railway signals.
8981. Jensen, P. ..... Pneumatic ordnance (*Pneumatic Dynamite Gun Company*).
8983. English, T. ..... Working ordnance by compressed air.
8984. Michelin & La Société Michelin et Cie. ..... Wheel tyres.
8985. Lake, F. C. ..... Machines for sewing thatch.
8986. Morecroft, G. T. ..... Power traction ploughs.
8987. Thirion, A. R. ..... Steam boilers.
8990. Lake, H. H. ..... Typewriters (*Hammond*).
8991. Lake, H. H. ..... Iron and steel (*Brown*).
8996. Wade & Cherry ..... Lubricating shafts.

11th June, 1890.

9003. Gell, W. J. ..... Disengaging gear for boats.
9010. McPhun, J. P. ..... Mortising machine.
9016. Morrison & Harper ... Steam engines, &c.
9018. Scott, R. ..... Lace machines.
9019. Shaw, E. ..... Hoisting machinery.
9020. Smith, F. E. ..... Rack pulley.
9025. Barsby, W. ..... Sewing machines.
9026. Roberts & Wheater ... Brakes.
9028. Brooks, S. H. ..... Spinning machinery (*Clarté*).
9035. Bayly, J. P. ..... Compound engines (*Rickie*).
9040. Bayly, J. P. ..... Windmill (*Ball & Ingram*).
9043. Bayly, J. P. ..... Plough (*Dodd*).
9045. Fisher, C. U. ..... Sugar cane mills (*Leblanc*).
9046. Haddan, H. J. ..... Air brakes (*Griffin*).
9051. Luke, J. ..... Paper-making machinery.
9055. Galloway & Beckwith Steam boilers.

12th June, 1890.

9067. Lucas, Lucas, & Loosley Crank drawer.
9069. Wrigley, M. H. ..... Rotary engines.
9071. Winter, T. ..... Yarn-sizing machines.
9077. Simpson, W. H. ..... Ring spinning.
9084. Moore-Thompson, A. ... Staff apparatus for controlling traffic on single-line railways.
9087. Masey, J. T. ..... Steam valve.
9092. Tozer & Stanton ..... Tramway wheels.
9094. Livesey, Sen., Livesey, & Livesey, Jun. ..... Looms.
9097. Freiber, C. ..... Feeding steam generators.
9098. Miller, J. (of the Firm of Smith Brothers & Co.). ..... Lubricating apparatus.
9099. Thomas, J. L. ..... Grist mills.
9102. Glover, L. ..... Looms.
9105. Mills, B. J. B. ..... Steam tow boats (*McDougall*).
9113. Afzelius, C. J. M. ..... Breechloading guns.
9117. Heintzenberg, J. ..... Looms.
9123. Dauber, A. ..... Iron and steel.
9126. Turner, E. R. ..... Roller mills.
9127. Donnithorne, E. G. M. Engines and pumps.
9131. Renouf, P. L. ..... Self-adjusting anti-friction bearings.
9132. Ball & Renouf ..... Tyres for wheels

13th June, 1890.

9134. Adams, R. B. F. ..... Locomotive regulators.
9137 9139. Lever, Holland, & Todd ..... Boiler furnaces.
9144. Bamford, S. B. ..... Grinding mills.
9149. Southall, C. H. ..... Boot machinery.
9153. Ubrig, E. ..... Moulding machines.
9156. Mintoft & Mintoft ..... Reaping machines.
9171. Smith, H. J. ..... Castings.
9173. Kern, F. A. ..... Bolting machines.
9174. Rickaby, A. A. ..... Packing for pistons.
9180. Waddle, H. W. ..... Ventilating fans.
9181. The Lucigen Light Company, Ld., & Jarmain ..... Oil flame furnace.
9186. Grimes, W. ..... Steam boilers.
9188. Wallace, J. ..... Marine governors.
9191. Sandino, A. ..... Boot machine.

14th June, 1890.

9201. Werner, J. R. ..... Marine governors.
9202. Werner, J. R. ..... Metallic packing.
9204. Waddington, J. ..... Looms.
9208. Teasdale-Buckell, G. T. Printing in colours.
9210. Casebourne, C. B. ..... Boiler cleaning tools.
9213. Brunton & Statter..... Valves for steam engines.
9215. Casebourne, C. B. ..... Boiler cleaning tools.
9220. Griffiths, W. B. ..... Sewing machines.
9221. Harmer, J. ..... Railway signals.
9223. Bradbury, A ..... Tentering machines.
9226. Strauss, J. ..... Lubricator for slide valves.
9229. Richardson, J. ..... Sand moulds.
9232. Gledhill, A. ..... Economiser speed-wheel engine.
9241. Mudd, W. R. ..... Boot burnishing machines.
9242. Thompson, W. P. ..... Machinery for tapping nuts (*Cook*).
9243. McClements, J. A. ..... Rollers for mangles, &c.
9249. Abell, G. C. ..... Propelling and steering vehicles.
9256. Baldock, W. H. ..... Winding yarns.

ELECTRICITY.

9th June, 1890.

8872. Suter, F. ..... Electrical lamp holders.
8892. Muirhead & Wright ... Insulating electrical conductors.

10th June, 1890.

8933. Felt, G. H. ..... Electro-deposition.
8959. Thomson, Sir W. ..... Mariner's compass.
8964. Kennedy, R. ..... Electromotors.
8988. Lake, H. H. ..... Magnetic separator (*Ball & Norton*).

11th June, 1890.

9030. Freedman, C. H. ..... Primary battery.
9061. De Ferranti & Wright Electric meters.

12th June, 1890.

9089. Henrie, Pückert, & Toennies ..... Arc lamps.
9101. Verity & Sons ..... Push switch.
9124. Aubert, J. J. A. ..... Electric counter.
9125. Kingsbury, J. E. ..... Telephonic apparatus (*Western Electric Company*).
9130. Heap & Sharp ..... Regulation of currents.

13th June, 1890.

9138. Bigland & Burns..... Arc lamps.
9163-4-5. Newton & Hawkins Switch.
9166. Newton, F. M. ..... Switches.
9197. Alexander, P. P. ..... Electrical fuses.

14th June, 1890.

9212. Statter & Brunton..... Electromotors for elevating.
9246. Ronczewski, J. ..... Electromagnetic separator.

CHEMISTRY.

9th June, 1890.

8884. MacFarlane, J. W. ..... Extracting gold.
8895-6. Read Holliday & Sons, Ld., & Holliday ..... Azo colours.
8900. Butterfield, J. C. ..... Sulphurised ores.
8901. Davidson & Davis ..... Treatment of alkali waste.
8908. Jordan, F. G. ..... Extracting gold.
8914. Crossley & Jones..... Ferric oxides.
8915. Guttmann, O. ..... Nitric acid.
8916. Ellershausen, F. ..... Extraction of lead.
8922. Peters, T. ..... Application of iron residues.

10th June, 1890.

8929. Cowper-Coles, S. O..... Coating metallic surfaces with alloys.
8942. Leith, J. ..... Sulphuretted hydrogen, sulphide of ammonium, and alkali.
8989. Lake, H. H. ..... Treating copper (*Cummins*).
8992. Lash & Johnson ..... Reduction of ore.

11th June, 1890.

9001. Willcox, B. ..... Colouring matters (*Farbenfabriken vormals Friedrich Bayer & Co.*).

12th June, 1890.

9080. Dawson & Hirsch ..... Phenolether and oxydiphenyl.
9112. Ellershausen, F. ..... Caustic soda.
9115. Bowman & Anderson ... Extracting precious metals.
9129. Lake, H. H ..... Artificial manure (*Nenninger*).

13th June, 1890.

9182. Western, C. R. ..... Extracting gold.
9183. Tichborne, Darley, Purcell, & Geoghegan ... Collection of carbonic acid gas.
9198. Wise, W. L. ..... Treatment of waste potassium salts (*Chemische Fabrik Buckau Actiengesellschaft*).
9200. MacIvor, R. W. E. ..... Ultramarine.

14th June, 1890.

9203. Millbourn, A. R. ..... Recovery of waste products.
9247. Edwards, E. ..... Desilverising lead (*Honold*).
9257. Wohle, S. ..... Aluminium.
9258. Imray, O. ..... Colouring matters (*Marburg*).

MISCELLANEOUS.

9th June, 1890.

8876. Hart, F. B. ..... Compensating signal wires.
8886. Garton, R. ..... Preserving and storing grass.
8905. Loftus, A. J. ..... Lamps for signals.
8919. Wilson, D. ..... Cement.

10th June, 1890.

8931. Parker, R. ..... Belt fastener.
8943. Thompson, W. P. ..... Artificial fuel (*Paternoster*).
8993. Daguzau, V. L. ..... Cement.

11th June, 1890.

9021. Rothwell, J. ..... Humidifying apparatus.
9060. Chabrand, L. V. ..... Ship's telegraph.

12th June, 1890.

9090. Moennich, P. ..... Automatic temperature regulators.

13th June, 1890.

9135. Craig, J. ..... Manufacture of paper.
9190. Gibb & Pierjus..... Manhole covers.
9195. James, T. S. ..... Cold dry air producers.
9199. Bowing, J. ..... Artificial fuel.

14th June, 1890.

9234. Mitton, T. E. ..... Heat regulator.

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given, give notice at the Patent Office, in the prescribed form of such opposition.

Year 1889.

6458. Hoho.
9904. Burn.
9949. Morrison.
10038. Wedlake.
10359. Maxim.
10538. Watson & Watson.
10879. Kreiss.
11063. Wills (*Armani*).
11349. Addison & Lloyd.
11393. Parker.
11445. Leadbeater & Leadbeater.
11528. Beyer & Hagen.
11582. Morgan.
11640. Bruce.
11667. Abel, Dewar, & Anderson.
11832. Dolby.
11844. Sleeman.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

Driving Pulleys.—*H. Lea, Birmingham.*—This pulley is designed for use on machines running at a high velocity, and where a good gripping surface for the belt is required, such as the small driving pulleys of dynamos. The body of the pulley is metallic and formed with a flange upon one side of its rim, whilst a loose flange is made to fit over the other side of the rim. Between these two flanges are wound round the pulley strips of leather with their edges at right angles to the axis of the pulley. When the surface of the pulley has been covered in this way by leather, bolts are passed through the loose and fixed rim and through the leather strips, and the whole bolted up. The leather is thus squeezed tightly between the flanges, and so held in place. Claims: (1) Covering metallic pulleys with leather or other like material in such a manner as to present the edge of the material to the surface of the driving belt for the purpose described; (2) the combination of the shroud—the metallic ring—and the screw bolts and nuts with the rings or strips of leather or other like material for the purpose described.—No. 12312. August 2nd, 1889. 8*d.*

Packing for Piston Rods, &c.—*A. M. Grant, Kilmarnock.*—The packing is metallic, combined, if desired, with the ordinary fibrous packing. It consists of a number of rings made of phosphor-bronze, whose inner surfaces are lined with some soft metal such as Babbits metal. The rings employed are of two sections; those that are placed against the ends of the glands are beveled, and their beveled surface faced with the soft metal, so that when the glands are tightened up the rings are forced against the piston rod, &c.; those rings between the end rings differ in section only by having square edges. The joints of the rings are alternately covered by outer rings of triangular form, one of the flat surfaces covering the joint. The other alternate joints are made by providing the rings with outer flanges upon the adjacent sides. These flanges thus make a broad joint, and are kept closed together by coiled springs. These springs surround each packing ring, and exert a pressure upon the sloping sides of the flanges and the similar sides of the triangular outer rings. As the packing rings are in segments, the force exerted by the coiled springs keeps them in close contact with the rod. Three claims are made.—No. 1213. January 23rd, 1890. 8*d.*

Friction Gearing.—*G. F. Evans, Somerville, U.S.A.*—To increase the friction of the driving and driven pulleys in machinery the inventor interposes between their faces a number of endless belts. The driven pulley is made with flanges, which may be removable. On the surface of this pulley are placed, side by side, three, four, or more endless leather belts, which are in length greater than the periphery of the pulley, but smaller than that of the flanges. The belts consequently hang loosely upon the pulley, yet cannot come off because of the edges. The driving pulley is brought to bear against the surface of one side of the belt, and the pulley bears against the other; thus the belt forms a friction-producing medium for the two. Claims: (1) The mechanism for transmission of power between two lines of shafting, composed of two shafts, two pulleys thereon, one being flanged, and a series of endless bands, which loosely encircle the flanged pulley and are adapted to travel independently between and be gripped by the pulleys; (2) (3) (4) approximately the same as claim (1).—No. 6139. April 22nd, 1890. 6*d.*

Propelling Vessels.—*J. S. Morton, New York, U.S.A.*—A new motor is the basis of this invention. A number of vessels, in shape a cone with a hemispherical base, are placed at the bow and stern of the vessel, with the apex of their conical ends protruding from the sides. In the apex of each vessel is a small aperture, through which water is forced or spurted, and the reactionary force of this water against the surrounding water propels the boat. Four or more of these vessels are placed at the stern, four at the bow with their axes longitudinal, and one upon each side of the forward part of the boat. They are all connected by pipes to a pair of double-acting force pumps, which are worked in any suitable manner by a motor. Water is sucked by the pumps from beneath the vessel, and forced by them through the pipes to one set of the vessels according to the direction in which the ship has to be moved. If the ship has to go ahead, the water is forced from the apertures of the vessels at the stern and *vice versâ*. The vessels at the side in forward part of the ship are used to assist the rudder in steering. Instead of making the pumps and conical vessels separately, they may be combined, and the plungers of the pump connected to the motor by suitable rods and levers. Six claims are made.—No. 6050. April 22nd, 1890. 8*d.*

Pumps.—*H. R. Cussons, Kingston-upon-Hull, Yorkshire.*—In this pumping apparatus the inventor makes use of a quantity of water previously raised to assist in raising more. The illustrations represent:—Fig. 1, a vertical section of the apparatus; Fig. 2 and 3, details of the same. As illustrated the pumping

FIG. 1

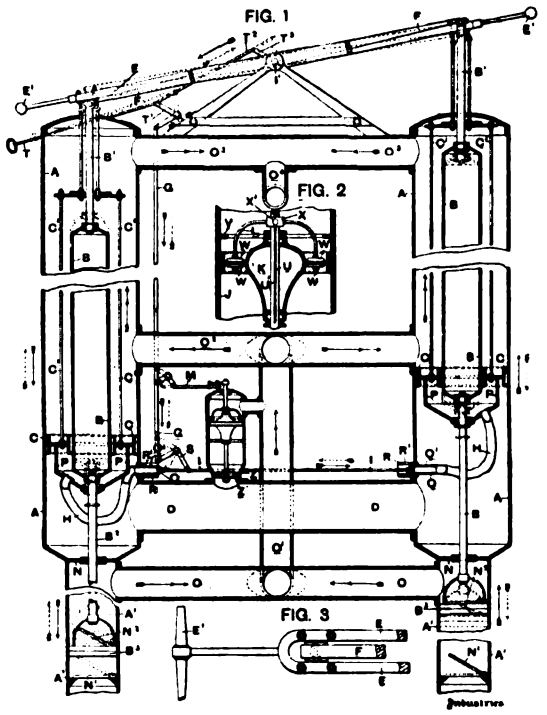

FIG. 2

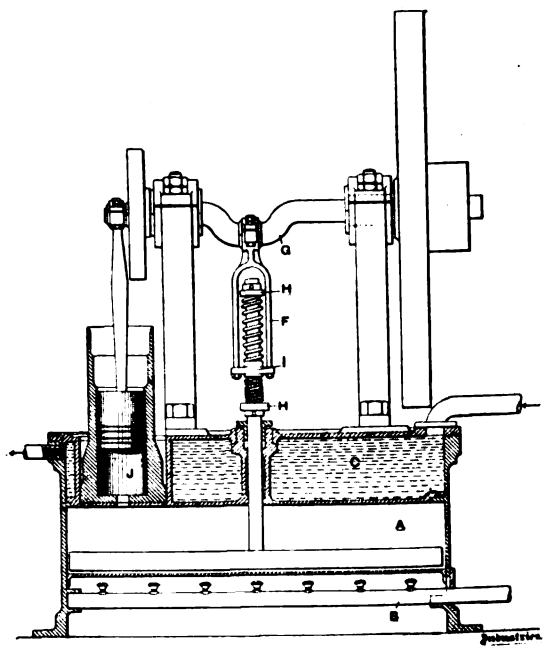
FIG. 3

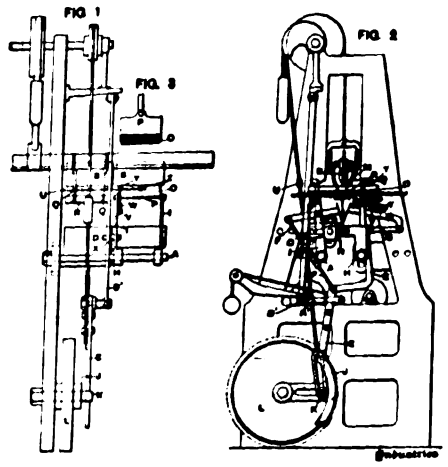


machine is constructed to be worked by hand, the levers E and F being provided for that purpose, the one working within the other as shown in Fig. 3. To each end of the lever F is secured a pump bucket B^3, which works in a barrel A^1 attached to the bottom of the main barrel A. The piston rod of the bucket B^3 passes through the bucket C of the main barrel, and it is enlarged into a hollow cylinder to constitute a piston for a purpose to be explained. The main buckets C are secured to the ends of the levers E. When the hand levers E and F are rocked it will be seen that the buckets in the pump barrels partake of a reciprocating vertical motion, and water is raised through the main valves N^1 and forced through and delivered from the apparatus in the direction of the double-headed arrows. Thus the buckets B^3 first raise the water and deliver it through the pipes O O^1 O^2 to the top part of the main barrels. It is then forced upwards by the buckets C to the pipes O^3 and delivery pipe O^4. To assist in raising the water as described the inventor admits water from the pipe O^1 to the pipe D and the under surfaces of the buckets C. The water is admitted to the pipe D through a float valve Z, part of which is illustrated in Fig. 2. In addition water is admitted and exhausted to and from the chamber P in the lower part of the bucket C, so forcing the hollow shaft B upwards to assist in pumping. The water is admitted from the pipe D to the chamber P through a flexible pipe H and valve Q. Upon the down-stroke of the buckets the valve Q exhausts the water from P and discharges it to the atmosphere. Claims: (1) The improvements in apparatus for pumping, raising, and forcing liquids as set forth and shown; (2) the method of and means employed for working the pumping apparatus referred to in the preceding claim by utilising a predetermined quantity or head of water as set forth; (4) the combination with the hereinbefore described pumping or liquid raising and forcing apparatus of a hollow pump spear or air vessel B, cap or plunger C, beams E F, and means for alternately filling and expelling water into and out of the chamber in the cap C, as and for the purposes set forth.—No. 4459. March 21st, 1890. 8*d.*

Drilling Hard Rock.—*E. Edwards, London.* (*O. Terp, Breslau, Germany*).—In order to drill deep holes in hard rock, and to obtain specimen cores from the holes, diamond rock drills have hitherto been used, and the well-known diamond drill system has been found to be both effective and reliable, but at the same time so expensive that it cannot be used under all circumstances. The present invention consists in the application of metal tubes to the above work. The tubes are made of soft metal, and work in conjunction with granular emery or other hard material. They are revolved upon their axes, and the emery or other substance fed to the working end of the tube. By these means holes can be drilled through hard rock easily and evenly, the cores so produced showing correctly the strata passed through. Instead of a tube of soft metal a hollow or solid cylinder of emery may be used with like results. When a metal tube is employed it is usually made of copper, zinc, tin, or soft iron. The method of working is the same as that when the diamond drill is employed. As very little emery need be used, and the tube is very slightly worn, the cost of working is small. Claims: (1) The apparatus for drilling deep holes in hard rock, consisting of a tube of soft metal, such as copper or soft iron, in combination with emery powder or other hard grinding material, which, by rotation of the tube, bores an annular hole, leaving a central core which can be withdrawn with the tube; (2) in drilling apparatus of the kind described in claim (1), the use of a hollow or solid cylinder of emery as described.—No. 122. January 3rd, 1890. 6*d.*

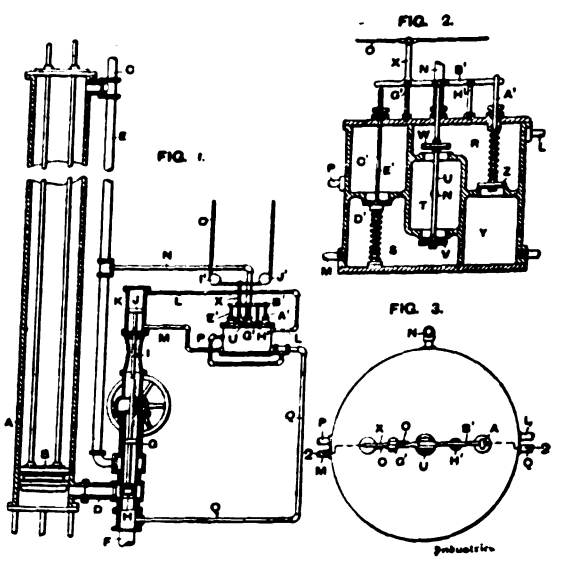
Transmitting Power by Chains.—*Avon Babo, Washington, U.S.A.*—By the employment of this invention reversible motions can be imparted to a wheeled vehicle from a chain running continuously in one direction along the track of the vehicle. This system is particularly adapted for use on cable traction railways where there is but one cable working in a street. When the car is running in the same direction as the cable, the former is rigidly secured to the latter, but when the motions are opposite there is brought into action a reversing device which transmits the motion of the chain to the wheels, and causes the car to travel in the opposite direction. Upon one of the axles of the car there is mounted a grooved wheel of such diameter as to extend through the slot into the conduit. This wheel is fitted loosely upon the axle, but may be secured to it at any time by a suitably arranged clutch. Immediately before and behind the grooved wheel, and in the same vertical plane, are two small sheaves mounted upon a frame suspended from the under part of the car. The cable passes over these sheaves and under the grooved wheel, the former keeping the cable up to and in contact with the latter. The frame upon which the sheaves are mounted can be raised and lowered at will so as to bring more or less of the cable in contact with the grooved wheel. When driving in the direction of the motion of the cable, the large grooved wheel is disconnected from its axle, and the sheaves are raised until the cable is bound between them and the grooved wheel. The grooved wheel is thus held stationary, constituting a grip for the cable whilst its axle revolves freely. To reverse the motion the wheel is secured to its axle by the clutch, and the sheaves are slightly lowered, so that the wheel is revolved by the motion of the cable, and the car is driven in the reverse direction. Six claims are made.—No. 678. January 14th, 1890. 8*d.*

Working Guns on Railways.—*T. English, Hawley, Dartford.*—This is a method of working and transporting guns on railways. The gun is preferably of the disappearing class, and it is mounted on a wheeled carriage, but the ordinary road wheels are replaced by flange wheels mounted at a width apart to suit the railway gauge. In addition to the gun carriage there is a four-wheeled truck similarly adapted to the railway, and having a hook which can be lowered by hand and made to engage with the trail eye of the gun carriage. When the hook has been so engaged it is re-raised, lifting the trail and securing the truck to the gun carriage ready for transportation. At the place where the gun is to be worked there is provided a strong and heavy foundation plate, having a pivot projecting up from it, and a circular path formed between the rails to the same gauge. The axle-tree of the gun carriage is brought directly over this pivot, and a shoe, which is rigidly attached to the trail brackets of the carriage, is made to engage upon the pivot. There is also provided outside the rails level circular segment plates on which the trail of the carriage slides. When in place the gun carriage is detached from its truck, and the gun revolved about the pivot, its wheels travelling upon the circular path whilst the trail slides over the segment plates. Claims: (1) For transporting a gun along a railway, the use of a four-wheeled truck with hook engaging the trail of the gun carriage as described; (2) for working a gun on a railway, the use of a foundation plate with pivot and circular faces or treads for traversing the gun as described.—No. 4825. March 27th, 1890. 6*d.*



Hot Air Engines.—*C. Wells, London.*—The air of this engine is heated by atmospheric burners consuming gas, and a more effectual and rapid heating of the air is obtained by making the stroke of the displacer shorter than that of the crank and causing the displacer to come into contact with the hot and cold plates of its vessel. To make the stroke of the displacer shorter than that

of the crank, the rod of the displacer is connected to the crank G by a forked connecting rod F. The fork F is jointed to the displacer rod by a loose collar I, which slides upon the rod between the springs H. By the use of these springs, the difference in the strokes of the displacer and crank is compensated for by the compression of the springs, so causing the displacer to come into contact with the plates at the ends of its strokes. The bottom end plate of the displacer chamber A is heated by the gas burners B, and the upper end plate is cooled by a circulation of water in the vessel C. The air, after having been heated in the chamber A, passes to the motor cylinder J, whose piston works the crank G. Claim: The combination with cylinder piston crank and displacer of displacer connecting rod as the latter is described with reference to the illustration.—No. 12999. August 17th, 1889. 6*d.*



Digitized by Google

HACKLING FLAX, &c.—*J. Erskine, Belfast, Ireland.*—These improvements are to dispense with the hand process of "ending" the fibrous material in hackling machines. There is employed in connection with the flax holder a nipping device which nips the fibre at a distance below the ordinary holder and removes the short ends as the fibre is raised and lowered by the holder. The illustrations represent Fig. 1 a longitudinal sectional view of the nipping or "ending" device and tumbling hackle, Fig. 2 an end elevation of the same, and Fig. 3 a hackling comb. The fibre M suspended from the ordinary holder B is gripped between a pair of nippers C D. One of these nippers C is stationary, and the other D is made to open and close upon the other by the lever E actuated by a bowl K in the disc L. Pivoted above the nipping device are levers F, which carry at one end the plates T and are

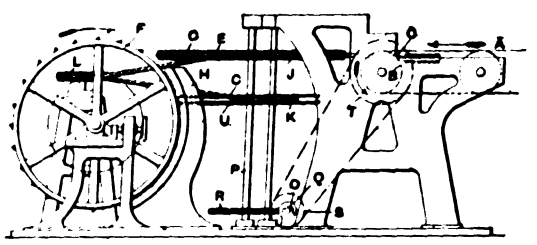
combined at the other end with the lever E. The action of this part of the device is as follows:—When the holder B is making a down-stroke the nipping device is opened and the fibre falls down between the nippers. Upon the holder making its up-stroke the nippers are closed by the bowl K pressing against the lever E, and the ends are removed from the fibre as it is drawn upwards. As the holder makes its down-stroke and the nippers are opened, the plates T are lowered by their levers and remove the ends from the face of the nippers. Between the nippers C D and the holder B are hackling combs O. The combs O have imparted to them a horizontal reciprocating motion, and are thus made to close over the fibre in its upward movement. India-rubber-faced pressers R are also arranged between the nippers and holder to press the fibre for "breaking." Claims: (1) The use and employment of a fixed nipping device for effecting the "ending" of the flax or fibre, operating and operated by means such as described and illustrated; (2) the use and employment of a finishing hackle either before or after the "ending" operation has been performed as described, such finishing hackle being employed in combination with the fixed nipping device; (3) the use and employment of a finishing hackle either before or after the "ending" operation has been performed, as described and illustrated.—No. 7695. May 8th, 1889. 11*d.*

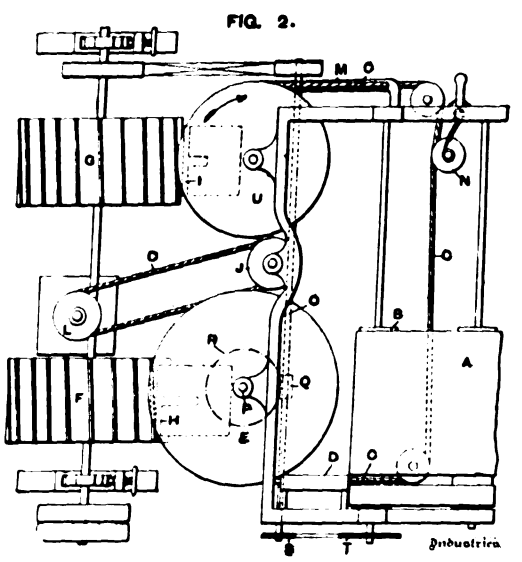
VALVES OF LIFTS AND ELEVATORS.—*W. P. Gibson, London.*—The improvements relate to the auxiliary valves for controlling the movements of the main valve in elevator mechanism. In the accompanying illustrations Fig. 1 is a vertical section of an elevator of the vertical type equipped with the improved auxiliary mechanism, Fig. 2 is a vertical section upon the auxiliary valve, and Fig. 3 a plan of the same. The hydraulic elevator has the usual power cylinder A and piston B, provided with the usual supply, discharge, and circulating pipes C D E. The main valve H has a vertical motion in the barrel C, and is controlled by the piston J in the cylinder K. Fluid under

pressure is admitted to the cylinder K by the auxiliary valve shown enlarged in Figs. 2 and 3. At the junction of the pipes D and E with the barrel G the outer casing is formed into an annular chamber and the barrel is perforated. The auxiliary valve casing is divided into five compartments; the compartment T communicates to the pressure fluid supply, R S communicate with the top and bottom of the cylinder K, and the compartments Y C¹ with the discharge pipe F. The operation of the auxiliary valve mechanism is as follows:—The parts are shown in their normal positions. To cause the downward movement of the main valve H, to permit the circulation of water from the upper te the lower end of the cylinder A, the attendant in the car draws the hand-rope O upwards around the pulley I¹. The lever X will then depress the valve D¹ and raise the valves V W, thus putting the chamber S in communication with the discharge pipe F through the pipe Q, and the supply chamber T in communication with the chamber R, so that the piston J is forced downwards. This downward motion of the piston J continues until the communication is formed between the top and bottom of the cylinder A. When the motion of the car is to be reversed the rope O is drawn upon in the opposite direction and the lever X moved in a contrary way, so closing the valves previously opened and opening those that were shut. The piston J is raised and the pressure fluid exhausted from A through D and F. To hold the piston J and valve H in any position it is only necessary to release the hand-rope; the valves V W are then both open, and the working fluid is admitted to both sides of the piston J. Three claims are made.—No. 20,959. December 31st, 1889. 8*d.*

RAMIE MACHINERY.—*M. J. Renaut, Paris, France.*—The improved machinery which forms the subject of this invention is for breaking and decorticating fibrous vegetable substances, and more particularly ramie, in a green state. Only the decorticating part of the machinery is here shown, Fig. 1 being an elevation and Fig. 2 a plan. The breaking machine consists of a pair of fluted crushing rollers to which the ramie is fed upon an endless band or apron. As the stalks leave the rollers they pass between a pair of circular rotary brushes for the purpose of removing the pellicle which covers the fibre and the pith which forms the inside of them. The broken stalks are then placed by an attendant upon a second apron A, which conducts them to the decorticating machine illustrated. They are next put with their heels across an endless rope C, and are kept there by a guide D until the moment when the rest of the stalk falls off the apron A. The rope C engages in the groove of a large pulley E, tightly

FIG. 1.





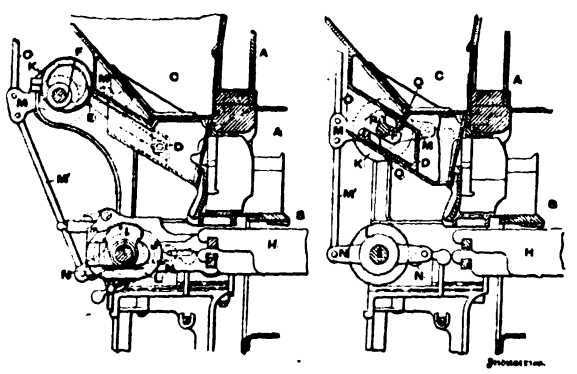


FIG. 2.

locking therein the stalks that it carries, and it brings them to a drum F fitted with blades and turning opposite a concave wooden block H so that the stalks pass between the drum and the concave block. By the friction of these the epidermis or pellicle which covers the fibre is removed and the ligneous part which was disaggregated by the breaking machine expelled. This first drum effects the complete decortication of three-fourths of the length of the stalks, but the heels held in the groove of the pulley have not been acted upon by the blades. The rope then leaves the large pulley E, and, still carrying the stalks, enters the groove of a small pulley J, about which it makes a half-turn, and the decorticated part of the stalks which hangs down is seized below by the rope on its entrance into the groove of a second large pulley U placed on a lower plane than the pulley E. The decorticated part of the stalks held in the groove of the second large pulley U draws the heels before the second drum G, which, like the drum F, has blades, and turns opposite a concave wooden block I. After the passage of the heels between the drum G and curved block I the decortication of the stalks is complete. On leaving the second drum the stalks present themselves across the rope in perfect parallelism and collect on a fork M, between the arms or prongs of which the rope passes to return by guide pulleys to the first large pulley E. For the purpose of keeping the rope of the machine tight a spring-mounted pulley N is brought to bear upon it. Claims: (1) The combination with a decorticating machine of several or a number of breaking machines which feed the decorticating machine by means of an endless apron common to all the machines as described; (2) in a breaking machine a regulating or controlling board for the purpose of feeding the ramie to the machine; (3) in a decorticating machine such as described, the arrangement or means described for tightening the cord while allowing it a sufficient amount of flexibility or "give"; (4) the decorticating machine constructed and working substantially as described and illustrated.—No. 12448. August 6th, 1889. 8*d.*

FEEDING FUEL TO FURNACES.—*J. J. & T. Vicars & J. Vicars, Jun.*—Reference is made to self-stoking furnaces in which fuel is fed to grate-bars by means of reciprocating plungers, and the fuel caused to travel through the furnace by means of grate bars carried forward in a body from the front towards the rear of the furnace and moved back in detachments, or one at a time. The mechanisms for feeding the coal to the bars, and moving it forward

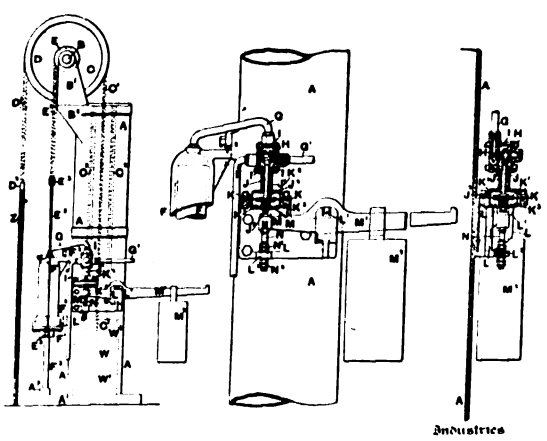

FIG. 1. FIG. 2.

on the bars, have hitherto been worked together; by the present invention they are worked independently, so that the rates at which they act may be better regulated. Fig. 1 is a vertical longitudinal section of the apparatus, A represents the furnace end of an internally fired boiler, B is the furnace, C is the fuel hopper, D are the reciprocating plungers for feeding the fuel to the furnace bars, and E is an eccentric and rod for giving reciprocating motion to one of the plungers. As many eccentrics and rods are used as there are plungers to be driven. H are the movable fire-bars, F the shaft for driving the plungers, and I the shaft for driving the bars. The above parts are of usual construction. To drive the motor shafts there are mounted on them the ratchet wheels K and L, and into the teeth of these engage the pawls M and N. The pawls are coupled together by the rod M¹, and a reciprocating motion given to them by a rod O connected to a suitable motor. As the feed plungers D and fire-bars H are actuated by means of separately operated driving shafts the speed of either portion of the apparatus may be varied without affecting the other portion. Fig. 2 is a vertical longitudinal section of a modification of part of the invention. Equivalent parts are denoted by the same letters as in Fig. 1. The fire-bar driving gear is the same as that shown in Fig. 1, whilst reciprocating motion is given to the plungers D by means of tappets P secured to the shaft F. Claim: In apparatus for feeding fuel to and in furnaces the combination of reciprocating plungers and movable fire-bars with separate driving shafts substantially in the manner and for the purposes set forth.—No. 10945. July 8th, 1889. 6*d.*

BOILER FURNACES.—*T. White & W. Carson, Govan.*—In a former specification, No. 6889 of 1887, the inventors described a damper regulating and actuating device for steam boiler furnaces; the present patent is for improvements in it. The damper is raised and lowered as the pressure of steam falls or rises. Fig. 1 of the illustrations shows an elevation of the complete apparatus, Fig. 2 is a sectional side elevation, and Fig. 3 a sectional elevation at right angles to Fig. 1. A is a hollow open-ended cylinder, which supports the whole of the mechanism, and encloses the counter-weights W W¹ W² of the damper Z. The weights W W¹ W² are connected to the damper by a chain passing over the pulley C, and they are in excess of the weight of the damper, so that the latter has a tendency to rise. A plunger F¹ of a ram cylinder F is connected by a frame and chain to a second pulley E upon the shaft of the first pulley C. By the connections it will be seen that as the plunger is forced out of its cylinder downwards the damper Z is lowered and *vice versâ*. Steam from the steam generator or water under pressure, is admitted by a D valve H to work the ram. The valve H is enclosed in a steam chest I, and it is coupled by a rod J to a diaphragm K¹. Communication is made between the steam chest I and the upper surface of the diaphragm, so that steam admitted from the generator to the valve-chest exerts its force upon the surface of the diaphragm. A lever M¹ is pivoted to a bracket on the side of the cylinder A, and its short arm made to

FIG. 3. FIG. 2. FIG. 1.

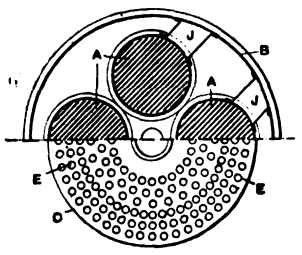
bear upon the under surface of the diaphragm with a force produced by the weight M² suspended from its longer arm. The action of the ram and valve fittings is as follows:—When the pressure of the steam in the boiler rises above the desired normal pressure, it acts on the diaphragm K¹ with a greater pressure than that due to the weight M² on its reacting lever M¹, and so presses down the diaphragm and opens the valve H of the inlet port I³ to the cylinder F, and presses out its piston or ram F¹ and so closes the damper Z proportionately to the outward

Digitized by Google

motion of its ram or piston. Immediately the pressure in the boiler *falls* again towards or below its normal pressure, the reacting weight M^2 and lever M^1 raise the diaphragm K^1 and spindle J of the valve H, so as to close the inlet port I^3 to the cylinder F, and open the exhaust port to the outer atmosphere through the valve, and allow the piston or plunger F^1 to rise again, and the damper Z to open, by the action of its counterweights W W^1. Claims: (1) The construction or arrangement and combination of the parts of a damper actuating and regulating apparatus for steam boiler furnaces, with a slide or equivalent valve connected to a disc or diaphragm within a close pressure chamber, and having a valve-chest and ports and a steel yard or other sensitive acting weighted lever, substantially as and for the purposes described in reference to the illustrations; (2) the fitting and use of a slide or equivalent valve connected to a disc or diaphragm within a close pressure chamber, and having a valve-chest and ports, substantially as and for the purposes described in reference to the illustrations.—No. 8600. May 23rd, 1889. 8*d*.

Vertical Boilers.—*G. Cawley, London.*—In this new form of vertical boiler greater strength and evaporative efficiency is gained, and economical working is ensured in boilers of larger size than those at present found practicable. The accompanying illustrations show—Fig. 1, a vertical section of the boiler, and Fig. 2, a horizontal section, half upon the line S T and half upon the line C C, looking upwards. The boiler has the appearance of a cylindrical vessel pinched in or reduced in diameter about midway of its length. The top and bottom parts thus formed are chambered out, the lower chamber A constituting the fire-box and the upper the uptake. A chamber H is formed around the boiler by neclosing its reduced portion. Communication is formed between this chamber H and the crown of the fire-box by short oblique tubes M; similar tubes are also used for the passage of the products of combustion from the chamber H to the uptake. It will thus be seen that in working the heated products of combustion

FIG. 2.



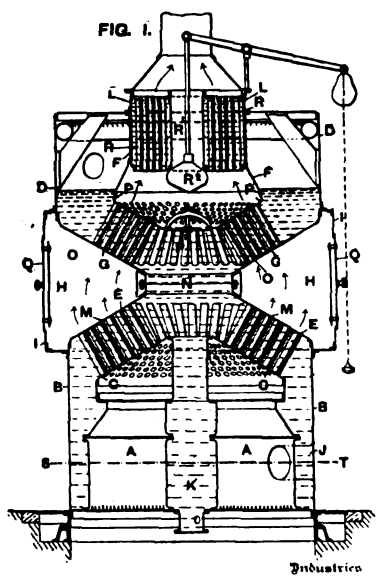


FIG. 1.

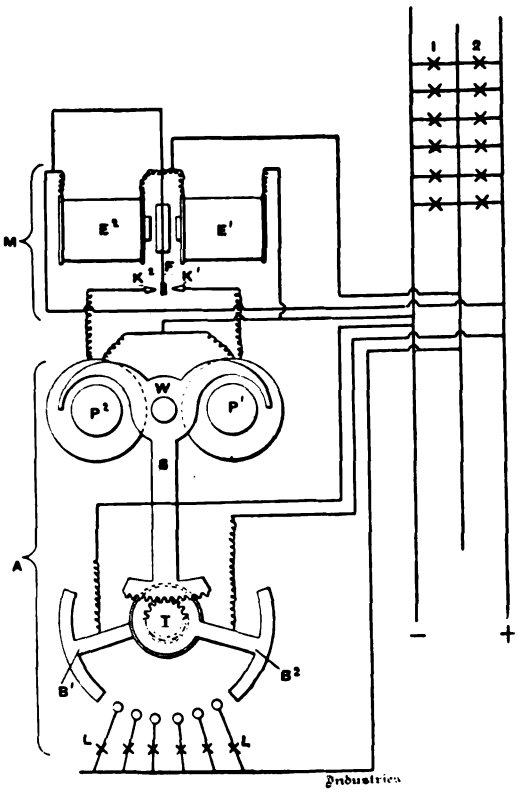
play first upon the inner shell of the boiler, next upon the outer shell, and then again upon the inner shell, as is indicated by the arrows in Fig. 1. A feed-water heater L, fitted with vertical heating tubes, is arranged in the upper part of the uptake, the heating effect being regulated by the valve R^2. To increase the resistance to collapse the cylindrical parts may be fitted with Adamson's rings or any other device. Claims: (1) In a vertical steam boiler, the combination and arrangement of a fire-box having its upper part of a conical shape, a lower shell surrounding the fire-box, and having its upper part formed to the frustum of a cone, and terminating in a short tube or opening, tubes connecting the coned top of the fire-box with the frustum of the lower shell, an upper outer shell terminated below by an inverted frustum of a cone and a short tube or opening connected to the tube or opening of the frustum of the lower shell, an inner tube in the upper part of the boiler having its lower end formed to the inverted frustum of a cone, tubes connecting the frusta of the shell and of the inner tube of the upper part of the boiler, and a plate or plates connecting the inner tube and the shell of the upper part of the boiler so as to enclose the steam space, as described and illustrated; (2) in a vertical steam boiler having the combination and arrangement of parts set forth in the preceding claiming clause, the construction, combination, and arrangement of two or more fire-boxes opening into a combustion chamber immediately below the conical top C as described and illustrated; (3) in vertical steam boilers a feed-water heater consisting of a vessel having tubes through which the hot gases from the boiler pass on their way to the chimney, constructed and arranged in the boiler as described; (4) the arrangement and combination of parts constituting the boiler described and shown in Figs. 1 and 2; and (5) the arrangement of a slight modification.—No. 10540. June 29th, 1889. 8*d*.

Separating Water from Steam.—*A. G. Brown, Bolton.*—This apparatus is for use in separating water from steam as the steam is passing away from a generator, so that the steam is practically dry before it is employed. It consists of a cylindrical chamber, having fitted in its upper part tangentially disposed inlet ways, these ways being prolonged helically within the cylinder. Concentric with the cylindrical chamber there is a large outlet pipe, which enters the chamber at the top and reaches nearly to its bottom. The action in the apparatus is as follows:—Steam from the generator enters the cylindrical chamber through the tangential ways, and has a centrifugal descending motion imparted to it. By this motion any water contained in the steam falls to the bottom of the chamber, and flows past a balanced valve back to the generator. The steam passes downwards until it reaches the lower edge of the outlet pipe, when it reascends and passes off to be employed. Claims: (1) Apparatus for separating water from steam, consisting of a chamber or vessel having two or more tangentially disposed inlet ways, a central uptake, and a balanced or weighted discharge valve as described; (2) apparatus for separating water from steam, consisting of a chamber or vessel having two or more tangentially disposed inlet ways, formed with spiral passages leading downwards, and a balanced or weighted discharge valve; (3) the combination of apparatus under the invention for separating water from steam with a steam generator as described.—No. 11600. July 20th, 1889. 6*d*.



Steam Boilers.—*D. T. Lawson, Wellsville, Ohio, U.S.A.*—In the specification of a former patent is described a process of preventing steam boiler explosions by retarding or prolonging the flow of steam from the water space to the steam space. This is done by means of a diaphragm or partition separating horizontally the top part of the boiler from the lower part at a point just above the water level. The theory by which the use of such a diaphragm is suggested is this—that the explosions in boilers are caused by the reduction of the pressure in the boiler by the sudden consumption of steam, and the consequent rapid evolution of more steam whose momentum is sufficient to burst the boiler. One of the causes which produce this sudden reduction of steam pressure is the sudden opening of the throttle valve to admit steam to the cylinder of an engine at starting, followed by the almost instantaneous closing of the steam ports. In the specification referred to communication between the two spaces in the boiler above and below the diaphragm is made through an adjustable valve. As this valve, however, requires very nice adjustment, the advantage of the invention could only be attained by skilled engineers. To make the invention more universally employable the inventor makes the communication between the spaces automatically adjustable. In the diaphragm are formed several openings, and over each opening is arranged a check valve opening upwardly and held down by a weight or spring. The aggregate size of these openings is considerably less than the size of the steam outlet from the steam space, so that steam will pass from the lower space to the upper somewhat slower than it will escape from the upper through the steam outlet. Another advantage of the valves so arranged is that they trap sedimentary matters that are thrown up through the valves on to the top of the diaphragm. The sediment can then be drawn off from the boiler by pipes suitably arranged. In addition to the check valve openings the diaphragm is pierced by a number of small holes which always remain open. Claims: (1) The steam boiler having its steam space separated from the water space by a horizontal diaphragm provided with openings in the same and combined with upwardly opening check valves arranged above the diaphragm as described; (2) the combination, with a steam boiler, of a horizontal diaphragm separating the steam space from the water space, and provided with upwardly opening check valves and gathering troughs for sediment and blow-out pipes extending through the boiler from the level of the troughs.—No. 11726. July 23rd, 1889. 8*d*.

Steam Engine Cylinders.—*L. St. Lawrence Pendred, Colchester.*—It is well known that when steam is exhausted from a cylinder the metal of the cylinder becomes cooled, and causes a portion of the steam admitted in the next stroke to condense. In order to reduce this condensation the inventor proceeds as follows:—An engine is made with one or more single-acting cylinders, and steam is supplied to these cylinders by separate pipes. One pipe conveys steam to one end of the cylinder for heating it, and the other conveys steam to the other side of the piston for working the engine. The end of the cylinder containing the heating steam is always in communication with the boiler. As the piston moves in the cylinder during the exhaust stroke, the heating steam follows it up and raises the temperature of the metal. The working steam will then find during the next stroke the metal at the same heat as itself instead of cooler. In applying the invention to compound engines, two pistons of different diameters are fixed to one rod and worked in tandem cylinders opened to one another. The heating steam is introduced between the two pistons, while the working steam is admitted first to the small cylinder and then exhausted to the larger in a manner which will be readily understood. Claim: Heating the metal of steam engine cylinders and preventing or diminishing evaporation in them by maintaining steam pressure in them as described. No. 12134. July 31st, 1889. 8*d*.

ELECTRICITY.

Fixing Electric Lamps.—*H. D. Ryder & H. E. Dopson, London.*—A convenient appliance is described in this specification for placing incandescent lamps into their places or for removing them, without the use of ladders or steps of any sort. It consists of a holder secured to the end of a wooden rod of convenient length to reach the different heights at which the lamps are placed. The holder is formed in the shape of a cup, whose internal diameter is approximately that of the external diameter of the lamp about one-third up. The inner edge of this cup is padded with a soft material such as rubber. To hold the lamp firmly in this cup, three spring fingers are secured to its edge, and project upwards so as to grasp the part of the lamp not entering the cup. The lamp is placed in the holder with the crown innermost, so that the stem remains free for insertion into suitable sockets permanently fixed in place. When the appliance is to be used for putting lamps into or taking them from suspended sockets, which can swing to and fro, or be easily lifted upwards, there is placed upon the rod just below the holder a tubular slide. To the slide are jointed, in the manner of scissors, two curved levers, which pass up upon opposite sides of the holder, and have their ends bent over the top of the holder. The lower ends of these levers are secured to a bow-shaped spring, which normally keeps the ends apart, but when pulled downwards by a wire attached to its centre, the ends of the levers are brought towards each other. The upper ends of the levers are made to seize the socket of the lamp and hold it firmly, whilst the holder seizes the lamp and removes it from the socket. Claims: (1) A friction clip-holder for electric incandescent lamps carried at the end of a rod as described, to enable such lamps to be readily put up or taken down; (2) the construction of the friction clip-holder in the manner described; (3) the construction of apparatus for putting up or taking down electric incandescent lamps as described.—No. 11296. July 13th, 1889. 8*d*.

Regulating Electric Potential.—*Siemens Bros. & Co., Ld., London.*—The accompanying diagram illustrates apparatus for the purpose of equalising the potential in the supply of two sets of lamps 1 and 2, notwithstanding that several of the one or of the other set may be cut out of the circuit. The apparatus consists of two main parts, what may be termed a meter M and a regulator A. The meter M consists of two electromagnets E^1 and E^2, with a spring armature F between their poles, which armature, according as it is attracted by the one or the other, makes contact at K^1 or K^2, and thereby closes the circuit for the one or the other of two relay electromagnets P^1 or P^2. Between the poles of these magnets is pivoted at W a three-armed iron lever S. Two of the arms are curved, so as to partly encircle the two poles P^1 P^2; the third arm terminates in a toothed segment, which gears with a pinion T. To the pinion are attached two contact arcs B^1 B^2, the one or the other of which is brought by the partial revolution of the pinion T to make contact introducing one, two, or more of a set of resistances, which may be lamps L The two main leads + and −, and the intermediate lead for the two sets of lamps 1 and 2 being connected as shown to the magnet E^1 E^2, P^1 P^2, and to the arcs B^1 B^2 and resistances L, when

the potential for the one set of lamps, say the set 1, exceeds that for the other set 2, the armature F makes contact at K^1, the magnet P^1 is excited, causing the lever S to move and the pinion T to turn so as to bring the arc B^1 over one, two, or more of the resistances L, which are thus introduced in the circuit of the lamps 1, making up for those of the lamps of the set 1 that may have been cut out of circuit. In like manner, should the potential for the set of lamps 2 be in excess, the regulating apparatus operates so as to introduce one, two, or more of the resistances L into the circuit of the lamps 2. When there are more than two sets of lamps, several of the above-described apparatus have to be used. Claim: Apparatus for automatically regulating the potential in the conductors for two or more groups of electrical lamps, consisting of the combination of a measuring and regulating apparatus, of which the former serves to compare the potentials existing in the said groups, and on the occurrence of any difference between such potentials, causes the regulating apparatus to be actuated so as, by means of a contact arm or other equivalent device, to include one or more resistances in the one group or the other, whereby the potentials in the two groups will be equalised as described.—No. 10699. July 2nd, 1889. 8*d*.

Copies of the British specifications may be obtained on application to H. Reader Lack, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every* 10*d*. *or fraction of* 10*d*. *Remittances exceeding one shilling must be made by Post Office Order.*

PREFACE.

When the future historian—in the calm seclusion of his study, and at a period sufficiently removed from the present to enable him to pronounce an impartial judgment—comes to give proportional values to the leading elements which have mainly constituted the material progress of the nineteenth century, he will, we believe, allot to the work of the engineer a highly important position. We use the term "engineer" in its widest sense, as we are thinking of the engineer's work as lying in no restricted technical groove, but rather in that extended domain where it has acted as a potent agent in bringing about social progress and international amity. The mechanical skill and daring enterprise of engineers have virtually reduced the surface of the earth and have brought the inhabitants of its various countries closer together. The latest and—as an isolated feature of engineering skill—the greatest example of such work is the Forth Bridge, to be opened by H.R.H. the Prince of Wales on the 4th March. The progress made with this magnificent structure has always been an attractive subject to place before our readers, and through the kindly assistance afforded us by the Engineers and Contractors, and their able lieutenants, we have been enabled very fully to describe and illustrate it from time to time. We have thought, however, that now the Bridge is finished, a complete illustrated description would be of interest to both technical and general readers, and with this object we have prepared the **Industries'** Special Number on the Forth Bridge.

The descriptive matter has been taken from the writings of several prominent members of the Engineers and Contractors' Staffs, and is therefore authentic. To the eminent Engineers and Contractors, and to each member of their respective staffs, we beg to offer our grateful thanks for their uniform kindness and courtesy. They have successfully brought to completion a gigantic piece of work which renders the nation indebted to them.

LIST OF AUTHORITIES CONSULTED IN THE PREPARATION OF OUR DESCRIPTION OF THE FORTH BRIDGE.

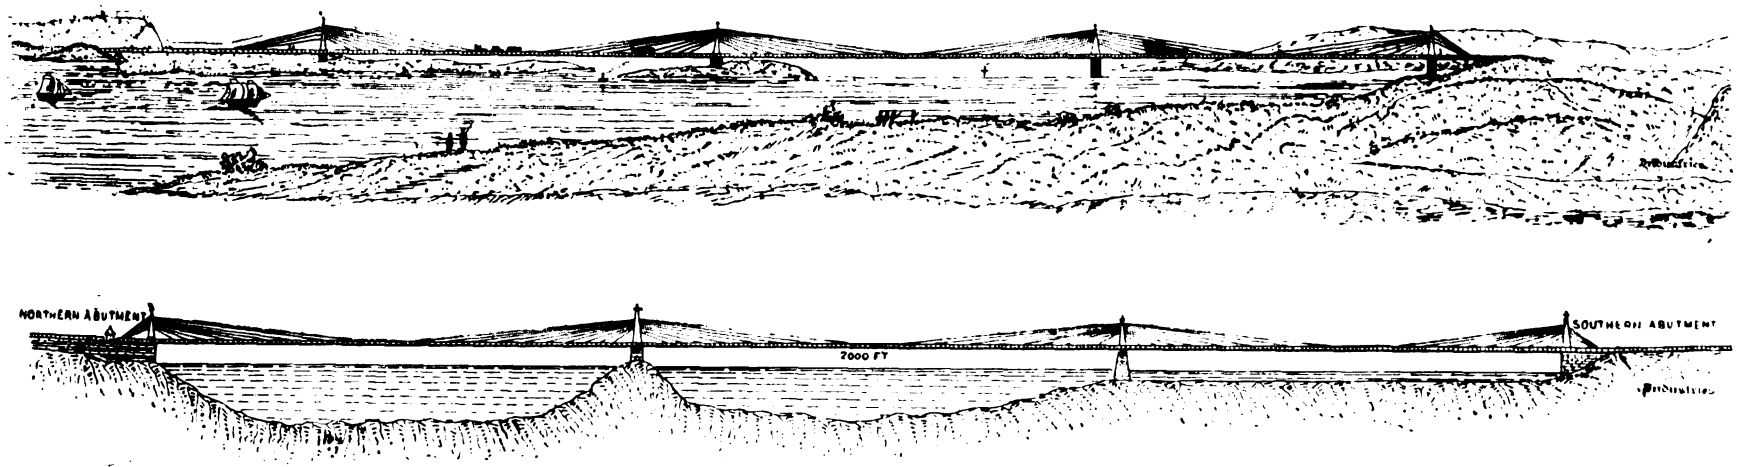
CONCLUSION	52

EARLY DESIGNS.

No novelty attaches to the idea of throwing a bridge across the Firth of Forth. As far back as the early part of the last century a proposal to construct a bridge carrying the main road to the North across the estuary was mooted; and again, at the commencement of the present century, an Edinburgh surveyor designed a suspension bridge on the same site, and with the same span, as the one whose successful completion marks so important an epoch in the annals of engineering. The drawings of this early proposal are still extant (See Figs. 2, 3, and 4), and show coaches and four being driven across the structure, whose total weight did not exceed 200 tons of iron!—the suspension parts being of wire ropes. The project fell into abeyance until about the year 1860, when the North British Railway Company experimented with the bed of the river opposite Charlestown. This point is some six miles west of the site of the present structure; and, though the Forth here widens out to some 2½ miles, the greater shallowness of the water compared with that between North and South Queensferry afforded grounds for hoping that a suitable route had been discovered. Four central spans, each 500ft., were proposed; the remaining ones being from 200ft. downwards. The sanction of Parliament was obtained, and land lines in connection were duly designed. The bed of the Forth proved, however, so unsuitable for founding piers—the soft soil being exceedingly unreliable and treacherous—that after a brief trial this route was definitively abandoned. A ferry scheme between Port Edgar and North Queensferry was next proposed, on much the same lines as that now plying between Granton and Burntisland further down the Forth. Details were even worked out, and the difficulty of transferring the trains to the boats, and again of disembarkation, was to be met by providing pontoons at the ends of the piers to rise and fall with the tide. This scheme, however, fell into abeyance. We now pass to Sir Thomas Bouch's proposed suspension bridge (See Figs. 5 and 6). This structure was to have occupied the exact site of the present one. Each large span was to have been 1,600ft. The main towers were designed to be 550ft. in height, and a clear headway of 150ft. at high water spring tides was provided for. In 1873 the Forth Bridge Railway Company was formed, and in the same year obtained the necessary legislative sanction for this structure, the estimate for which was placed at about £1,250,000. Although this type of bridge was not one generally considered applicable for the passage of railway trains, no positive objection was taken to it. The contract was let, workshops erected, brick yards laid out, and a commencement made. A small brick pier on the island of Inch Garvie in mid-channel, still standing, marks the inception of an undertaking destined so shortly to abandonment. How little thought Sir Thomas Bouch and the party accompanying him, that fresh breezy day, when they sailed from South Queensferry to Inch Garvie, and there laid the foundation stone of the projected work, that a terrible disaster was impending, which should cause the cessation of all their designs, and that finally the Forth Bridge should be accomplished on other lines and by other hands! Operations were suspended owing to the fall of the Tay Bridge during the destructive gale that raged in December, 1879; and an Abandonment Bill was consequently promoted in the Session of 1881.



INCEPTION OF THE PRESENT UNDERTAKING.

At this stage the North British, Great Northern, North Eastern, and Midland Railway Companies, being interested in securing direct communication to the North of Scotland, which should enable them to compete with the West Coast Companies for traffic on equal, if not more favourable terms, and wishing to save an enterprise so advantageous, instructed their respective consulting engineers, Sir John (then Mr.) Fowler, Mr. Harrison (since deceased), and Mr. Barlow, to fully investigate and report on the whole undertaking. On the 4th May, 1881, the above-named engineers submitted their joint report, unanimously agreeing that the steel bridge (See Figs. 7, 8, and 9, subsequently adapted to Figs. 10 and 11) on the cantilever and central girder system, designed by Sir John Fowler and Mr. Benjamin Baker, was not only the least expensive, but the best suited for the situation. The Abandonment Bill, which had passed the House of Commons, was accordingly withdrawn, and in 1882, the necessary plans having been deposited, an Act was obtained authorising the construction of a continuous girder bridge across the Firth of Forth from North to South Queensferry, having two spans of 1,710ft., two of 675ft., fourteen of 168ft., and six of 50ft.; a clear headway of 150ft. at high water spring tides being allowed; the engineers for the work being Sir John Fowler, K.C.M.G., and Mr. Benjamin Baker.

THE CANTILEVER SYSTEM.

Pausing now to consider briefly the principle on which the bridge has been built, we are led to examine the word "cantilever"—a scientific term, now rapidly becoming popularised through its intimate connection with the Forth Bridge. A cantilever may be defined as a bracket, those composing the Forth Bridge being double brackets—*i.e.*, like two ordinary jib cranes placed back to back. The connection between the ends of each set of double brackets is made by a central girder. No novelty attaches to this principle; as a matter of fact, it is a pre-historic arrangement. In the earliest Egyptian and Indian temples will be found the stone corbel and lintel combination, which illustrate this mode of construction, whilst in the oldest, as also in the most modern, wooden bridges will be seen practically the same thing in timber. Skeleton bridges on the same principle have for ages past been thrown by savages across rivers, a very interesting example having been found on the route of the Canadian

Pacific Railway. A bridge built in Thibet some 230 years ago forms another interesting illustration of the principle under discussion. Lieutenant Davis, R.N., who formed part of the embassy to the Court of the Teshoo Lama in Thibet, sketched this bridge in 1783, and published an illustrated account of it in London in 1800. The book was a popular one, and was translated and republished in German. It contains probably the first published description of a "cantilever and central girder" bridge. "The bridge of Wandipore is of singular lightness and beauty in appearance. The clear span measures 112ft.; it consists of three parts, two sides, and a centre, nearly equal to each other; the sides, having a considerable slope, raise the elevation of the centre platform, which is horizontal, some feet above the floor of the galleries. A quadruple row of timbers, their ends being set in the masonry of the bank and the pier, supports the sides; the centre part is laid from side to side." "Making allowance," says Mr. Baker, "for difference of material, this work may faintly be looked upon as the prototype of the Forth Bridge."

Passing on to more modern times, we find the cantilever and central girder system in constant application in designs by engineers. Thus, in 1850 Mr. Edwin Clark touched on the principle; Sir John Fowler, in 1845, experimented with a large wooden model; whilst Mr. Barton in 1855, Mr. Latham in 1858, and Professor Ritter, of Hanover, in 1862, all drew attention to the principle, and wrote concerning it. In 1859 Mr. W. H. Barlow, and again, in 1864, Mr. Sedley, took out patents in connection with bridges of this class; whilst a further patent in 1865 by Mr. E. W. Young had reference to the same subject. The Forth Bridge is by no means the first proposal of Sir John Fowler and Mr. Baker on the cantilever principle. In 1864 these engineers designed a proposed Severn Bridge on this system. The struc-

ture was to be built in steel, a span of 1,000ft.—subsequently, however, reduced to 600ft.—being provided. The Act was obtained, and the contract duly let, when financial difficulties supervened, and the bridge fell into abeyance. Similarly in 1871, and again in 1873, they designed bridges on this system for crossing the Severn and the Tees respectively—the one to be 800ft. span, the other 650ft. span; whilst, in his well-known book, "Long-span Bridges," a work republished in Philadelphia, and translated into German and Dutch, and published in the *Transactions of the Austrian and Dutch Engineers*, Mr. Baker in 1867 enforced the economical advantages of the continuous girder of varying depths. In 1876 two of the designs for the proposed New York and Long Island Bridge—viz., those by the Delaware Bridge Company and by Colonel Flad—were on this system. In 1876 a railway bridge of 148ft. span, across the Warthen, near Posen, was erected on the cantilever and central girder principle. From the foregoing remarks it will be seen that no novel or untried principle is claimed in the construction of the Forth Bridge. Turning now to applications of the cantilever principle since the inception of the gigantic undertaking at Queensferry, we note the almost universal adoption of the system, a fact abundantly speaking for itself. On the Canadian Pacific Railway numerous bridges are designed on the cantilever principle. The cantilever bridge at Niagara Falls, designed by Mr. Charles C. Schneider, has a span of 470ft., and is composed of two cantilevers The central girder is 120ft. long, the shore ends of the cantilevers being held down by anchorage piers of masonry. Work was commenced at the site on April 15th, 1883, and the structure was opened for traffic on December 20th of the same year. This bridge, the total length of which from centre to centre of anchorage piers is 910ft. 3in., carries the Michigan Central Railway across the Niagara River, about two miles below the celebrated Falls, and about 300ft. above the Railroad Suspension Bridge. The steel cantilever railway bridge across the St. John's River, at St. John, province of New Brunswick, Canada, was completed in 1886:—Messrs. J. & T. Abbott being the engineers. The total length of the bridge is 813ft., the centre span being 477ft. The shore arms of the cantilevers are of unequal length, being 143ft. and 191ft. respectively. The centre span is 143ft. 6in. This work was carried out by the Dominion Bridge Company, Montreal.

The "Jubilee" Bridge, carrying the East Indian Railway across the River Hooghly, is another example of a cantilever bridge. The structure, which is built for a double line of railway (5ft. 6in. gauge), has a centre double cantilever 360ft. long, the two main side spans being each 420ft. long, giving a total length of 1,200ft. for the bridge. The total weight of steel employed is 3,900 tons. The greatest height of the cantilever is 52ft., the girders being 30ft. 8in. apart from centre to centre. The side spans are 47ft. deep in the middle, and the girders 30ft. 8in. apart from centre to centre. Work was commenced on the site in 1882–3, the actual bridge construction not being begun till March 2nd, 1884, when the first caisson was launched. The structure was completed in December, 1886. The total cost of the bridge, including the approach viaducts, was £261,000.

The bridge over the River Indus, at Sukkur, is another example of the cantilever type, and was designed since the commencement of the Forth Bridge. The Sukkur Bridge carries the N.W. State Railway of India over the Indus, which at that point is divided by the island of Bukkur into two channels. The Sukkur channel is crossed by three spans, 278ft., 238ft., and 95ft. respectively; whilst the second, or Rori channel, is cleared by one single cantilever span of 820ft. The maximum height of the bridge is 169ft., the central girder being 206ft. span. The circumstances of this channel—viz., a depth at low water of about 80ft., with a rise of 16ft., and a current in flood of some nine miles an hour—rendered desirable the adoption of cantilevers and the overhang method of building, with consequent dispensation of all staging. The bridge was completed in the middle of 1889. Sir A. M. Rendel was the engineer. A feature of interest was its erection in this country in 1886–7 at the works of the builders, Messrs. Westwood, Baillie, & Co., of Poplar, previous to being despatched. A huge temporary staging, employing some 2,300 loads of timber, was required for this purpose.

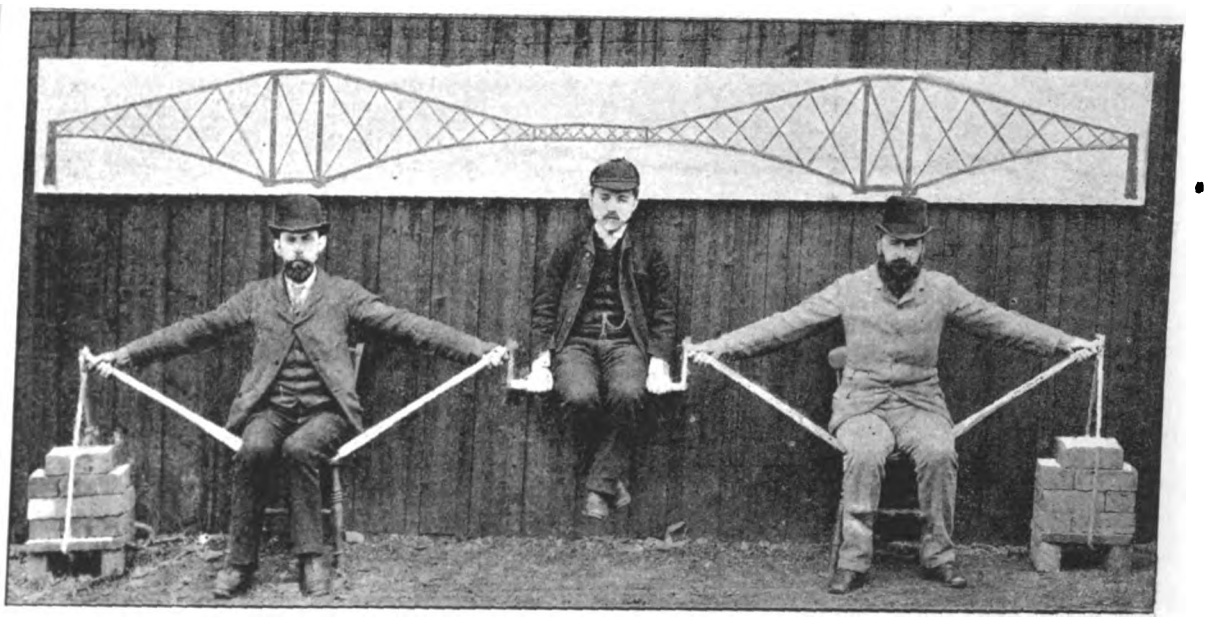

FIG. 12.—THE HUMAN CANTILEVER. SEE PAGE 6.

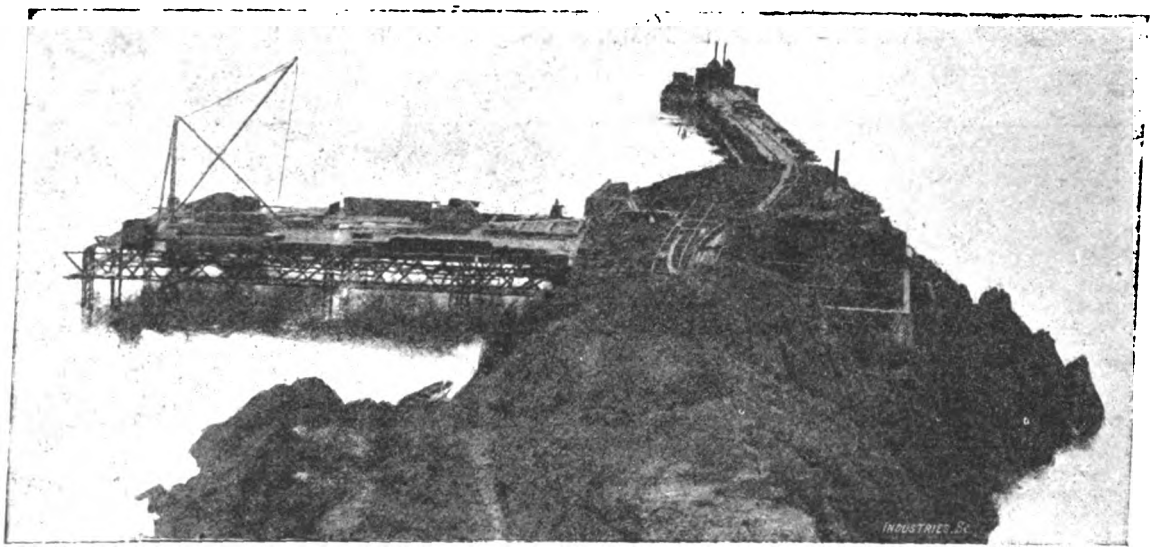

Fig. 13.—INCH GARVIE, JULY, 1883. SEE PAGE 8.

Passing on to proposed bridges in which it is intended to have recourse to the cantilever principle, we may briefly note the designs for a bridge at New York, with a span of 2,800 feet, by Mr. Lindenthal, with whom is associated in this enterprise Mr. B. Baker. The Channel Bridge, a stupendous undertaking recently mooted by Messrs. Schneider & Co., of Creusot, and M. H. Hersent, with Sir John Fowler, K.C.M.G., and Mr. B. Baker as consulting engineers, is designed with cantilever spans. This gigantic proposal to connect England and France by a bridge 24½ miles in length is estimated to require one million tons of steel, and to involve an expenditure exceeding £34,000,000. The main spans are 1,640ft. and 984ft., the lesser ones 830ft. and 328ft., a clear headway of 150ft. at high water being provided for. The piers, 120 in number, founded in a maximum depth of some 30 fathoms, present features of considerable difficulty. The project has been gone into with great consideration and elaboration, and

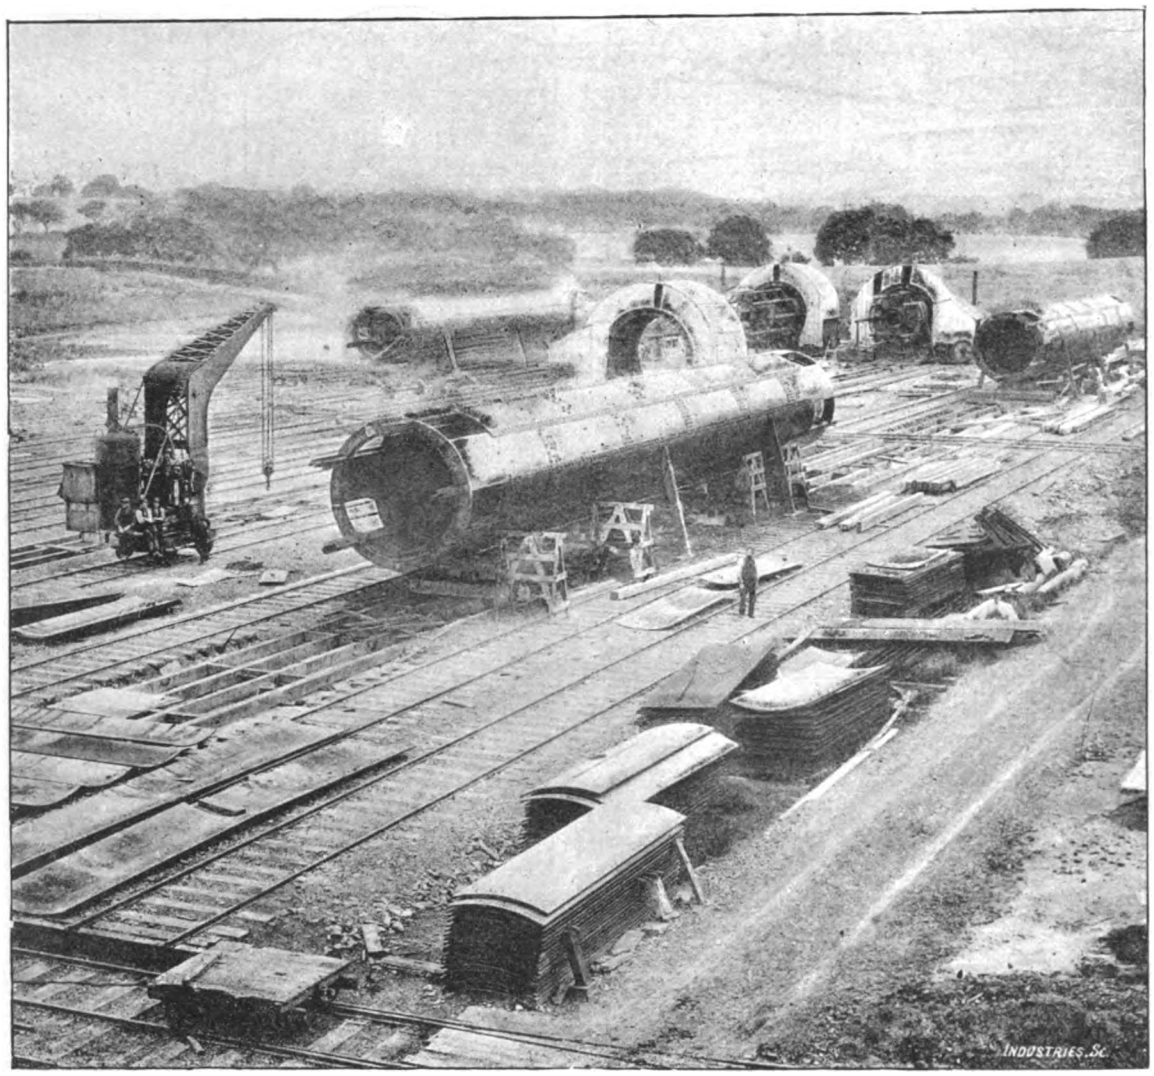

FIG. 14.—THE DRILL ROADS, AUGUST, 1884. SEE PAGE 8.

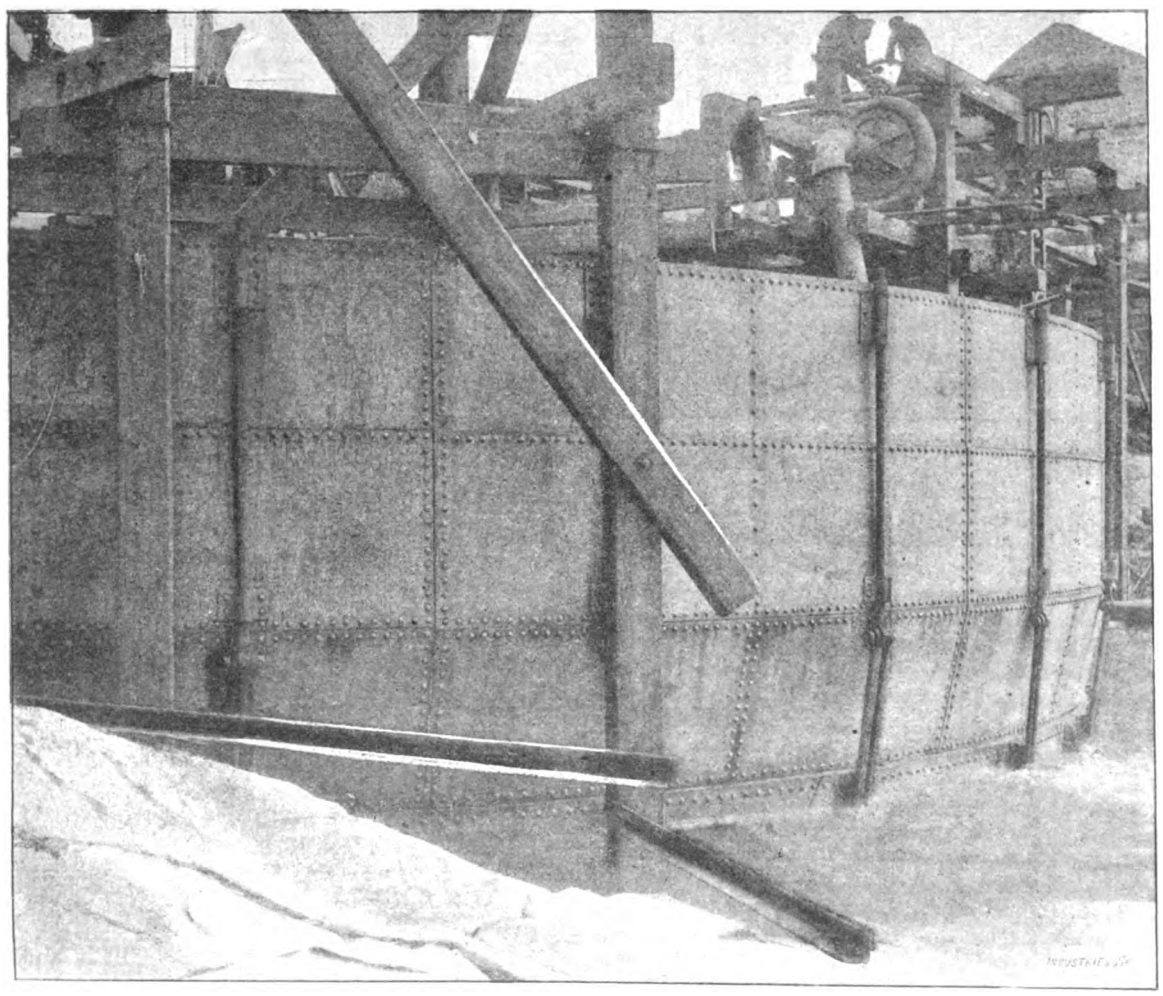

FIG. 15.—INCH GARVIE NORTH-EAST CAISSON AT LOW WATER, MARCH, 1884. SEE PAGE 9.

was prominently brought forward at the recent meeting of the Iron and Steel Institute in Paris.

ILLUSTRATIONS OF THE CANTILEVER PRINCIPLE.

"You, who have seen," remarked Mr. Baker in his lecture before the Literary Institute in Edinburgh in November last, "the three great steel piers spring out of the ground, and spread their branches right and left, will know that Nature has herself bridged many streams on the same principle that we have bridged the Forth. You have only to imagine two trees on opposite banks of a stream, and a third tree on an islet in the middle, extending their branches until they are mutually interlaced, and you have the natural cantilever bridge." What is known as the "Human Cantilever"—viz., a living representation of the principle introduced in the Forth Bridge—is now so fully popularised as to need but passing notice. The simile is best described by quoting Mr. Baker's own words. When lecturing before the Royal Institution, on May 20th, 1887, he first made his illustration of the living cantilever public, and said:—"Owing to the arched form of the underside of the bridge many persons hold the mistaken notion that the principle of construction is analogous to that of an arch. In preparing for this lecture the other day, I had to consider how best to make a general audience appreciate the true nature and direction of the stresses on the Forth Bridge, and, after consultation with some of our engineers on the spot, a living model of the structure was arranged as follows:—Two men, sitting on chairs, extended their arms, and supported the same by grasping sticks butting against the chairs. This represented the two double cantilevers. The central girder was represented by a short stick slung from one arm of each man, and the anchorages by ropes extending from the other arms to a couple of piles of bricks. When the stresses are brought on this system by a load on the central girder, the men's arms and the anchorage ropes come into tension, and the sticks and chair legs into compression. In the Forth Bridge you have to imagine the chairs placed a third of a mile apart, and the men's heads to be 360ft. from the ground Their arms are represented by huge steel lattice members, and the sticks or props by steel tubes 12ft. in diameter and 1¼in. thick." (See Fig. 12.) Further similes have been applied to the principle involved in the Forth Bridge. Two men, endeavouring to shake hands across a stream a little too wide, form a connection by grasping each end of a walking-stick. The men form the cantilever, the walking-stick the central girder.

LEADING DIMENSIONS OF THE BRIDGE.

The length of the structure is 8,296ft., or 376ft. over 1½ miles. The south abutment consists of four elliptical arches, each 57ft. span and 19ft. rise. It is built of rock-faced granite, with dressed granite parapet and strong corners, and carries the Forth Bridge Railway over the existing North British line. The viaduct spans, each 168ft. from centre to centre of piers, bring us to the south cantilever end pier. A side span of 675ft. carries the bridge to the Queensferry main piers, spaced 155ft. centres in the line of the structure and 120ft. centres apart at right angles to that line. The main span to Inch Garvie is 1,710ft., a similar distance separating the north shore from Inch Garvie—the spans over both north and south channels being identical. The Inch Garvie main piers are spaced 270ft. by 120ft. from centre to centre. The Fife main piers are spaced similarly to those at Queensferry. A half-span, corresponding to that on the south, brings us to the north cantilever end pier, and the bridge finishes in five viaduct spans similar to those already described, and three masonry arches of granite, 50ft. span. The clear headway under the centre of the bridge is 150ft. above high water, and the highest part of the bridge is 361ft. above the same datum. In the centre of each main span is a central girder of 350ft. span. From the base of the deepest pier to the top of the cantilevers the

Digitized by Google

total height is 450ft. (See Figs. 10 and 11.) The ratio of the size of the Forth Bridge to that of the other largest railway bridges was shown by a simile of Mr. Baker's, in his paper before the British Association in 1882. This now famous comparison took a powerful hold on the popular imagination, and it is not too much to say that scarcely a popular article relating to the bridge has since appeared in which some reference is not made to Mr. Baker's happy illustration of the magnitude of the giant structure. We append the words he then used:—"On glancing through the last volume of 'Reports of the British Association,' with a view to obtain a notion as to the ordinary length of papers in Section G, I incidentally obtained a notion also for illustrating in popular, but perfectly accurate, terms the size of the Forth Bridge as compared with the largest bridge in this country. In the report of the Anthropometric Committee it was stated that the average stature of a new-born infant is 19·34in., whilst the average height of the Guardsmen sent out to Egypt has been officially given at 5ft. 10½in. The figures have a ratio of 1 to 3·65; and, singularly enough, as the largest railway bridge in this country, the Britannia Bridge, has a span of 465ft., and the Forth Bridge a span of 1,710ft., the ratio there also is 1 to 3·65. Hence, to enable any one to appreciate the size of the Forth Bridge, we have merely to suggest the following simple rule-of-three sum:—As a Grenadier Guardsman is to a new-born infant, so is the Forth Bridge to the largest railway bridge yet built in this country. Bridges a few feet larger in span than the Britannia have been built elsewhere, but they are baby bridges after all."

COMMENCEMENT OF THE PRESENT UNDERTAKING.

In the autumn of 1882 tenders were invited for the Forth Bridge, and from the applications sent in two were selected, and on December 21st, 1882, the contract with the combined firm of Messrs. Tancred, Arrol, & Co., was signed, the members of this firm being Sir Thomas Selby Tancred, Bart., Mr. William Arrol, Mr. Travers Hartley Falkiner, and Mr. Joseph Phillips.

The Forth Bridge Railway Company, though supported by four leading railway companies, is a separate undertaking. The shares possess an absolute and perpetual guarantee of 4 per cent. per annum, as from July 1st, 1882, by the Midland, Great Northern, North Eastern, and North British companies, and debenture stock interest is also guaranteed by the same companies, the payments under the guarantee, if any, to be made in the following proportions:—Midland, 32½ per cent.; Great Northern, 18¾ per cent.; North Eastern, 18¾ per cent.; and North British, 30 per cent. After payment to the several companies of the amounts advanced under their guarantees, all surplus revenue is to go to the North British Company. The directors of the company at the present time are Lord Colville, K.T., and Lord Hindlip, representing the Great Northern Railway; Mr. J. D. Dent and Sir Matthew White Ridley, Bart., representing the North Eastern Company; Mr. W. U. Heygate and Mr. M. W. Thompson, representing the Midland Company; the Marquis of Tweeddale and Lord Elgin, representing the North British Railway Company; and Mr. S. Brunton and Mr. J. H. Renton, appointed by the shareholders—Mr. G. B. Wieland being secretary. Owing to the absence of Lord Hindlip Mr. F. W. Fison occupies his seat on the board.

PROGRESS DURING 1883.

Active operations were commenced on the site early in this year. The first thing to be done was the setting out of the centre line, and subsequent determination of the positions of the piers on the ground. A special observatory was erected at Port Edgar, to the west of the bridge, and, by means of a 12in. theodolite and standard measuring rods, 12ft. in length, the utmost accuracy was sought. We do not propose, in the limits of this account, to enter into any minute details of the setting out, a work of no small anxiety, when the responsibility thereby entailed is considered, and of no slight difficulty in a locality rugged and precipitous, and with all the accompanying hindrances of exposure to weather on the banks of a Firth notoriously squally, and frequently so hazy that the best instruments procurable would fail to detect marks and posts painted as conspicuously as possible at only a few yards distance. Every device in the shape of shelters, wind screens, and heavily loaded plumb-lines was adopted to avoid delay in windy weather.

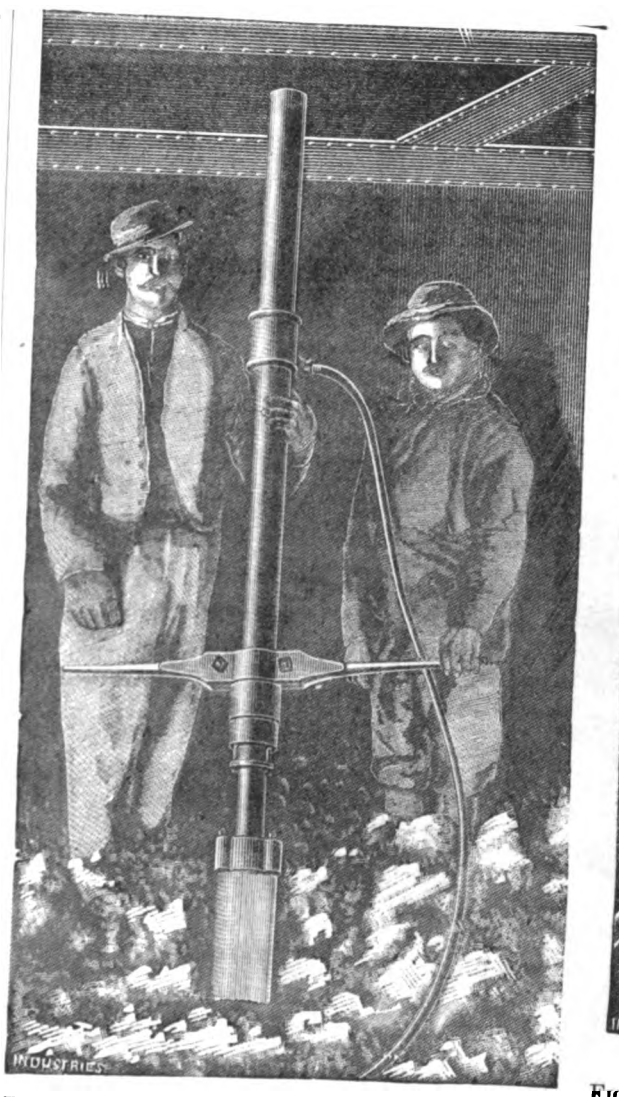

FIG. 16.—HYDRAULIC DIGGER. SEE PAGES 10, 15, 19.

FIG. 17.—ROCK DRILL USED FOR THE FOUNDATIONS OF THE PIERS. SEE PAGES 15, 18, AND 19.

SETTING OUT.—The following interesting account of the setting out, and the method adopted of finally checking by direct measurement the results arrived at by triangulation, appeared in the *Times* newspaper of October 10th, 1883:—

"To fix the position of the piers of a bridge, having two clear spans of 1,700ft., and two of 700ft., across a channel 200ft. in depth, is not so simple a problem as may appear to some persons. In the case of the Forth, the banks are more or less precipitous and the country undulating, so that it was difficult to get a base line for a trigonometrical measurement. At the request of Mr. Fowler, the Ordnance Department kindly sent a party of sappers to recover the old stations used in the Ordnance Survey of Scotland, and to take the necessary additional observations to determine the width across the Firth of Forth. The calculated result differed about 1ft. from that obtained by Messrs. Fowler and Baker's engineers, which is not much, perhaps, in a difficult measurement of over a mile across deep water, but enough to make it desirable that it should be set right. Mr. Baker held the view that it was possible to measure the 1,700ft. span to the eighth of an inch if necessary, and last week the measurement was made without any difficulty whatever. A length of 1,700ft. was first measured, with what may be termed absolute exactitude, along a straight piece of the North British Railway, and posts of a certain height were firmly fixed at each end. A steel pianoforte wire was then hung from these posts, with a sag or droop of 24ft. at the centre, and marks were fixed at each end of the wire to indicate the 1,700ft. length. The wire was then coiled on a roller and taken on board a steam launch, from which it was laid, like a submarine telegraph cable, across the channel of the Forth. It was then hauled up above the surface of the water, till it hung with the original droop of 24ft., when, assuming the temperature to be the same, the marks put on the pianoforte wire should indicate the required span of 1,700ft. This process was repeated several times, and the wire taken ashore to the railway, to test whether it had stretched, but all the observations were in exact accord. The sensitiveness of this simple mode of measuring the span with a wire weighing only 8lb. in all was quite astonishing. Thus, when Mr. Baker slacked out the wire only ¼in. in the 1,700ft., Sir Thomas Tancred, one of the contractors, who was in a boat in the centre of the Forth, at once signalled there was too much droop in the wire. At another time he signalled that it was too high, but a reference to the thermometer showed that the temperature had fallen two degrees, so that the wire proved itself a most delicate indicator of changes of temperature. The officers and crew of Her Majesty's ship 'Lord Warden,' the ironclad guardship anchored immediately above the site of the bridge, have always taken much interest in the works, and while the measurement was being made they very kindly manned their boats and regulated the traffic past the spot. Engineers and contractors engaged in carrying out a giant bridge across a stormy estuary, and reaching to a height twice as great as that of the topgallant masts of the 'Lord Warden,' could desire no better neighbours than Captain Kennedy and his well-disciplined and willing crew of 300 bluejackets."

The base line, measured along a straight siding connecting the Forth Bridge works with South Queensferry Station, had a total length of 4,013·2ft. The triangulation was then proceeded with by means of a 7in. theodolite made by Messrs. Negretti & Zambra, a 12in. transit theodolite, divided to 10 seconds, by Messrs. Cooke & Sons, of York, being

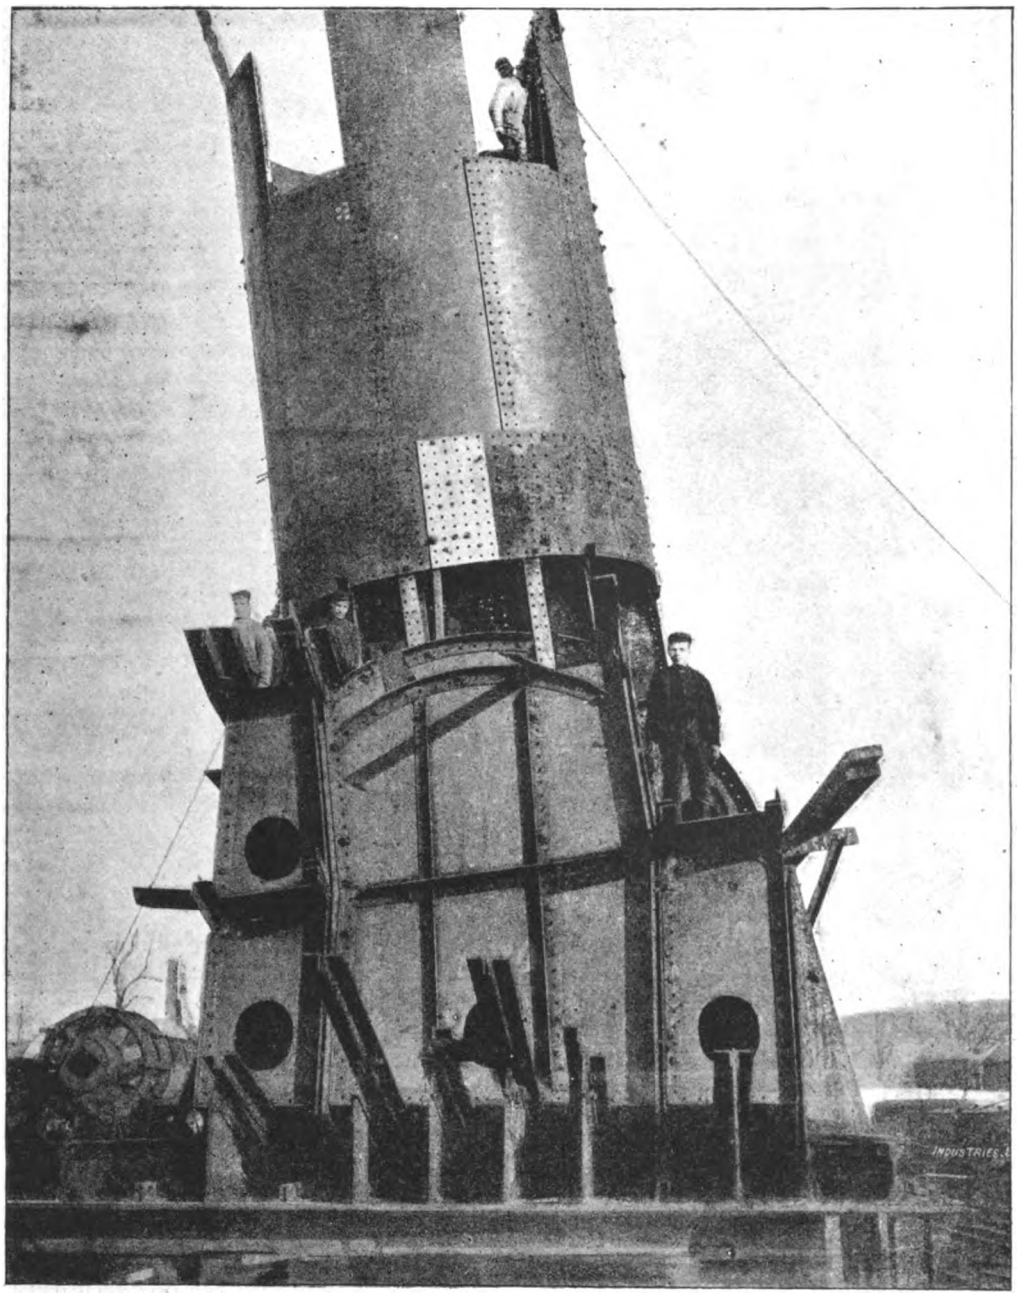

FIG. 18.—ONE OF THE SKEWBACKS, FEBRUARY, 1885. SEE PAGES 11, 13, AND 22.

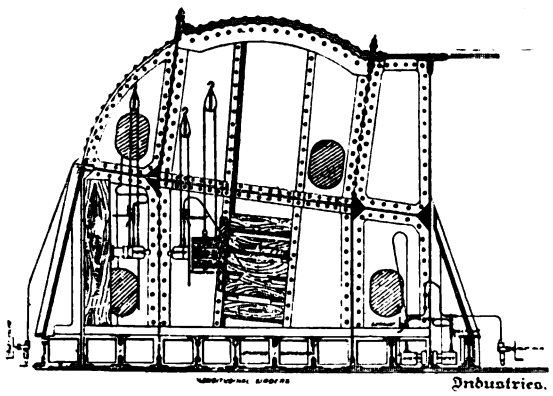

FIG. 19.—SECTION OF SKEWBACK. SEE PAGES 11, 13, 22, AND 24.

subsequently procured and used for the work. The 12ft. standard rods already referred to were of white pine, and 3in. square, the ends being of brass for 6in., with steel faces cast in. One end was rounded, the other forming an obtuse angle; both ends had screws for adjustment, and the latter one also a hardwood wedge, held in position by a split pin. The stations were marked by white poles, with three or four black rings some 2in. deep painted on each, such arrangement being found to be most easily distinguished. A 20in. reversible level, tripod type, by Messrs. Cooke & Sons, York, was employed for the main levels. With this instrument placed on the island of Inch Garvie, levels on the south or north shore, at some 2,000ft. distance, could be read with accuracy. It may be here noted that the principal theodolites and levels had cross-lines scored on glass diaphragms, an arrangement which showed them sharp and clear, with the further additional important advantage of being comparatively practically indestructible. The greatest nicety being required, copper bolts, with centre punched marks, were employed as bench marks, in lieu of the ordinary crosses or arrows cut on stone or baulks of timber. The usual steel bands and steel tapes were employed, care being taken to allow for changes of temperature, &c.

TEMPORARY WORKS, 1883.—Passing on to consider the temporary works erected during the first year of active operations on the south shore, the sheds which were erected when Sir Thomas Bouch's scheme was commenced, and had remained since the abandonment of that project untouched, were forthwith overhauled, and prepared for the reception of further machinery, an additional shed being added at a slightly higher elevation to the south. Twenty acres of ground around these sheds at the summit on the Hawes Brae, and to the south of the road leading from South Queensferry to Edinburgh, were enclosed, and substantial brick offices for the engineers and contractors' staffs were forthwith erected on this site. The equipment of the workshops was at once commenced, and gas furnaces, engines, and a large hydraulic accumulator, capable of working the whole of the hydraulic cranes, bending presses, &c., at a pressure of 1,000lb. to the square inch, were put in hand. Before the close of the year numerous hydraulic cranes, several drilling machines (See Figs. 101–107, &c.), the hydraulic bending machine (See Figs. 94 and 95), and two large travelling cranes, in addition to a large quantity of other plant, were in operation. The drill roads (See Fig. 14), on which the skewbacks were subsequently fitted and the tubes drilled, were laid down, and the temporary wooden jetty, on the east of the bridge, was built for some 1,800ft. from the south side, and the spurs to the viaduct piers added. An inclined plane of timber, connecting the jetty with the workshops above, was also completed in this year. Numerous cement stores, general stores, cottages for workmen, a large canteen and reading-room were also built, and the nucleus of the large fleet of steam barges, tugs, and launches subsequently employed was formed. On Inch Garvie (See Fig. 13) a large wrought iron landing-stage was erected, and a viaduct of the same material, connecting the island with a detached rock, Craig Sparry, to the west, completed. Air compressers were erected, and hydraulic accumulator plant was also laid down. On the north shore the temporary works erected during 1883 comprised two timber landing-stages, numerous cottages, workshops, and stores. Air-compressing machinery was also laid down, to work the drills employed in clearing away the rock for the foundations of the main piers.

COMMENCEMENT OF PERMANENT WORK.—Turning now to the permanent work executed in this year, and examining that carried out on the south shore first, good progress was made with the viaduct piers. Nos. 1 to 6 inclusive were successfully founded, and the masonry carried up to heights ranging from 2ft. to 32ft. above foundation. A commencement was made with the cofferdam of No. 7, and that for the south cantilever pier was in hand. The foundation of No. 1 viaduct pier was on boulder clay and above high water mark. No. 2, also above high water, was on hard freestone. Nos. 3, 4, and 5, also on hard freestone, were between high and low water, and were performed by tidal work; whilst Nos. 6 and 7 were founded in timber cofferdams of the usual construction. The viaduct piers were 25ft. by 8ft. at the top, and 50ft. by 20ft. at the base. The batter was 1 in 32, with a radius of curvature of 320ft. "The masonry of the viaduct piers and cantilever end piers consists of an Aberdeen granite facing, averaging a little over 2ft. in thickness, of rock-faced work, backed up with cement concrete or with rubble masonry set in cement, and bonded, about every 12ft. in height, with courses of large stones carried across the entire area of the piers." The first of the Queensferry caissons was commenced this year, being built up on the beach at South Queensferry, a little to the east of the bridge, on launchways. At Inch Garvie the excavation of the rock for the foundations for the north-west and north-east piers was commenced, and by the end of the year that for the latter was completed and progress with the caissons well advanced.

On the north side all four main piers were in hand before the close of 1883. The south-west pier was well advanced, and nearly ready for the caisson. A large amount of excavation had been done on the south-east, whilst a commencement had been made with the north-east. The north-west pier, situated above high water mark, was well advanced this year, the masonry being begun; the first wrought iron bond belt, 18in. deep by $\frac{3}{4}$in. thick, riveted up in position; and the 48 holding-down bolts, $2\frac{1}{2}$in. diameter and 24ft. long, being fixed in position and partially built in. The holding-down bolts are of steel, and fasten the bed-plates and superstructure of the main span to the piers. A cast iron anchor plate is placed at the root of each bolt. Progress was also made with the north cantilever pier, and the north approach viaduct piers and the north abutment.

The former, founded on whinstone rock benched out had been built by the end of this year some 16ft. above foundations, whilst the four viaduct piers had all been founded on whinstone rock, and the masonry carried up to heights ranging from 8ft. to 34ft. above foundation level—viz., to the same level above O.D.—and the height at which the viaduct girders were to be built on them preparatory

Digitized by Google

to the "lift and build" process by which they were elevated to their final position, the piers being built up under them as they rose.

During this year the whole of the holding-down bolts (576 in number) were delivered at South Queensferry. These bolts were made at Landore, in Wales, and had a tenile strength of 30 tons per square inch, with an elongation of 20 per cent. in a length of 8in. The whole of the screwing was done on them in a special screw-cutting machine at the bridge works. Upwards of 1,000 tons of steel plates and bars were delivered up to the end of the year under consideration at South Queensferry, and a commencement made with the construction of the internal tees and angles in the large tubes. The bed-plates for the North Queensferry north-west main pier were also delivered, and planed. Some 70,000 cubic feet of granite were delivered, of which 38,000 cubic feet were set, and about 5,000 cubic yards of concrete were put down during this year.

PROGRESS DURING 1884.

The temporary work executed during this year at South Queensferry comprised the completion of the timber jetty, 2,200ft. in length by 50ft. wide, and fixed about 7ft. above high water; the erection at the head of this staging of three powerful air-compressers, with engines and boilers, for supplying air to the four Queensferry caissons; and the construction of about half of the staging between the south viaduct piers, on which the viaduct spans were subsequently to be built, previous to the commencement of lifting operations. The question of water supply was carefully considered during this year, and before its close storage reservoirs, one at the Dalmeny Oil Works, and the other on a piece of rising ground to the south of the drill roads, were in operation. Amongst a large amount of plant added to the workshops may be more especially mentioned two machines for cutting the key-holes in the bed-plates; also a special tool for riveting them by hydraulic pressure; whilst a third seven-ton travelling crane was added to the drill roads. Additions were made both to No. 1 and No. 2 workshops, and the drill roads were likewise added to; besides an immense amount of other necessary temporary work imperative for the execution of so vast an undertaking.

On Inch Garvie progress with the wrought iron staging on the south-east portion of the island was steadily continued during this year, and additions to the main landing platforms were also carried out. The old castle on the summit of the rock was roofed in and modernised, affording accommodation for the workmen. Various minor shops, sheds, and smithies were also erected.

On the north side a landing stage was made at Carlinose, and those portions of the old coastguard station which were left standing were adopted for offices and dwelling-houses. The new coastguard station on the cliff above the former one was erected, as its predecessor stood on the centre line of the bridge, and on the spot now occupied by the Fife north main piers. Numerous minor sheds, &c., were erected on the north side during this year, and stone-crushing machinery to prepare material for concrete was set to work at Carlinose.

Passing on to the permanent work executed during this year, and commencing as usual at the southern side, and with the viaduct piers, the cofferdam for the last viaduct pier (No. 9) was completed by the end of the year, and the remaining piers carried up to the final level of the first stage—27·00 O.D.—viz., the height at which the viaduct spans were erected on them previous to the commencement of lifting.

A commencement with the erection of the viaduct span was made in the autumn of this year, staging for the erection of the five southernmost spans between pier and pier at level 27·00 O.D. having been previously fixed. The viaduct girders, it may here be explained, were 168ft. spans centre to centre of piers. The girders, which were continuous over two spans, have a depth of 22ft. 6in., and are 16ft. apart from centre to centre. They are of the lattice type, the permanent way being laid on the top. The weight of each span is about 200 tons, and the camber given was 1½in. The troughs for permanent way, floor plates, and wind fence are identical with those for the internal viaduct subsequently described.

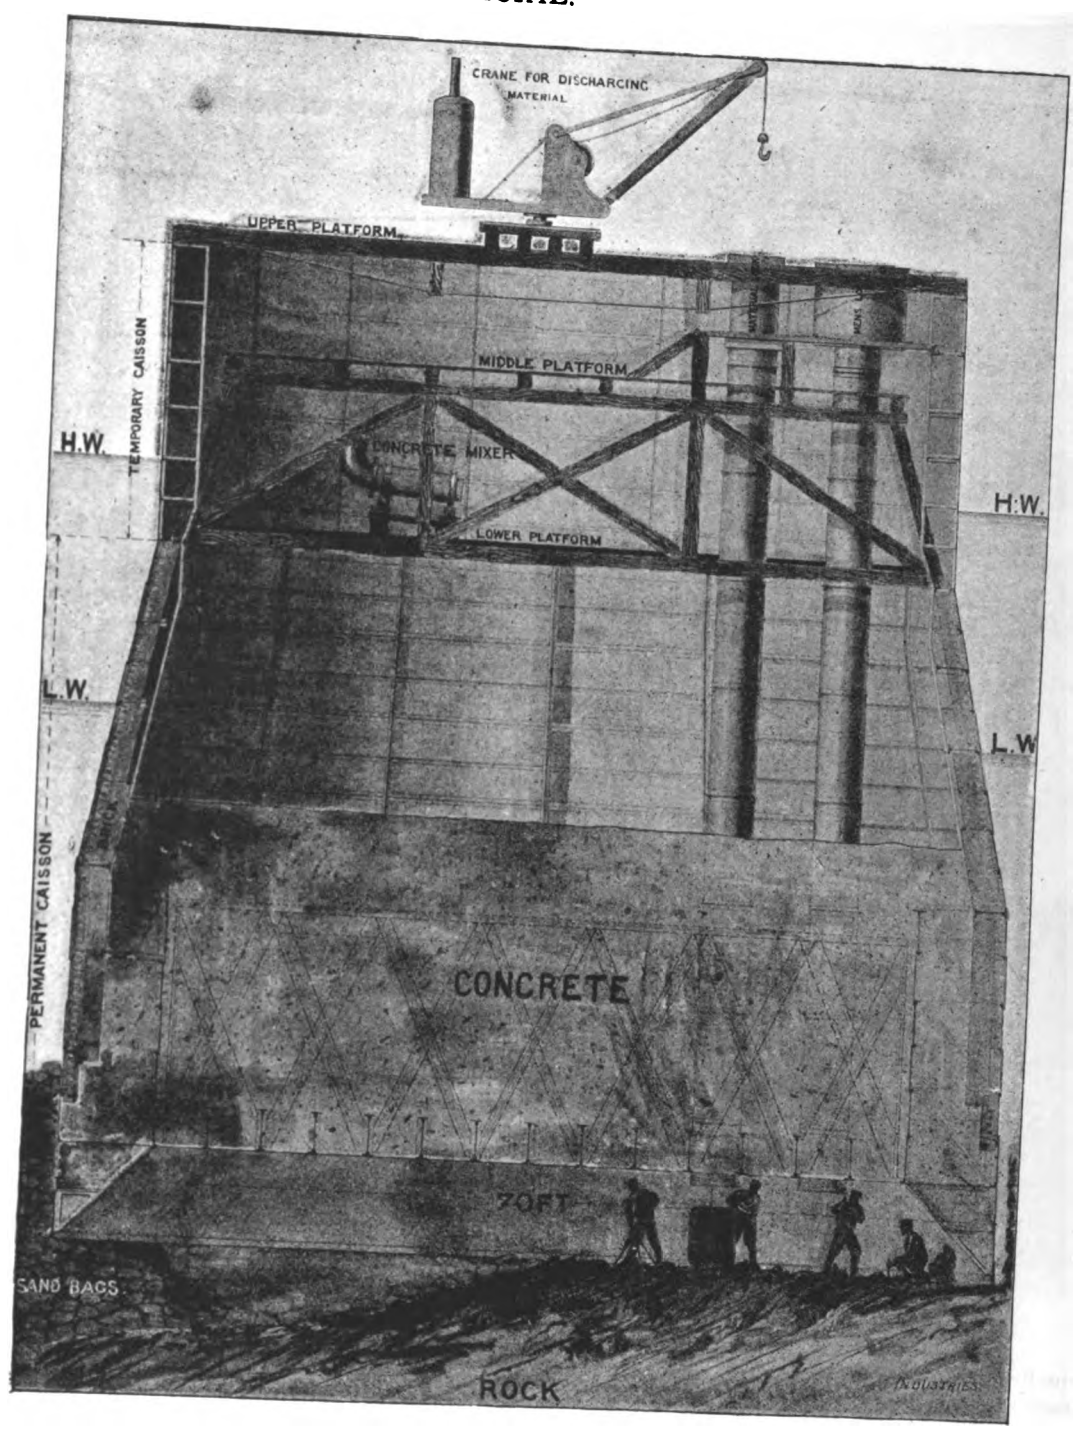

FIG. 20.—INCH GARVIE DEEP CAISSON, 1885. SEE PAGES 13, 15, AND 18.

The steel used throughout in the viaduct spans is mild steel, having a tensile strength of 30 to 33 tons per square inch, with an elongation in 8in. of 20 per cent., the customary requirements as to bend-tests being fulfilled. It is interesting to note that, originally designed for iron, they were constructed of steel to amended drawings, at the request of the contractors, with a view to economy.

Leaving now the south cantilever end pier, the cofferdam, begun in 1883, was completed during 1884. It "was necessarily a very substantial structure, being a quarter of a mile from the shore. It measured 126ft. by 75ft. over all, and had a double row of whole timber piles, with 4ft. of puddle between, and internal struts, chain cable ties, and external raking struts, and piles of great solidity and strength. A highly satisfactory bottom on boulder clay of rock-like hardness was found at a depth of 35ft. below high water." The cofferdam was very successfully constructed, being absolutely dry. The masonry was raised to the coping during this year.

At Inch Garvie the north-east main pier (See Fig. 15) was successfully founded, and the masonry completed. This pier was founded by means of a half-tide cofferdam of wrought iron segments, well shown in the illustration, a good deal of tidal work having to be done on this pier, as well as on the north-west one, before the cofferdams could be placed in position. In his paper, before the British Association at Montreal, in 1884, Mr. Baker thus alludes to this work:—

"At Inch Garvie delay and trouble were experienced in carrying out the shallow piers. Some of the work could only proceed at low water of spring tides, and it generally happened to blow hard just at that long-waited-for moment. Tidal work, and even half-tide work, are proverbially slow and worrying; but we were all determined that, as the rock varied in quality, no foundation should be put in until the bottom had been laid dry. By perseverance and patience this has hitherto been accomplished, and we have the satisfaction of knowing that both the rock foundation and masonry are unexceptionable in strength and solidity. In our shallow rock foundations at the Forth we had much the same problem to deal with as Stephenson encountered thirty years ago when building the fine bridge across the St Lawrence at this city, and our contractors dealt with it in much the same way."

The foundations of all four main piers on Inch Garvie are on whinstone rock. The main piers themselves, the first of which, on Inch Garvie, was completed this year, are thus described by Mr. Baker in his paper just quoted, and as the account is

Digitized by Google

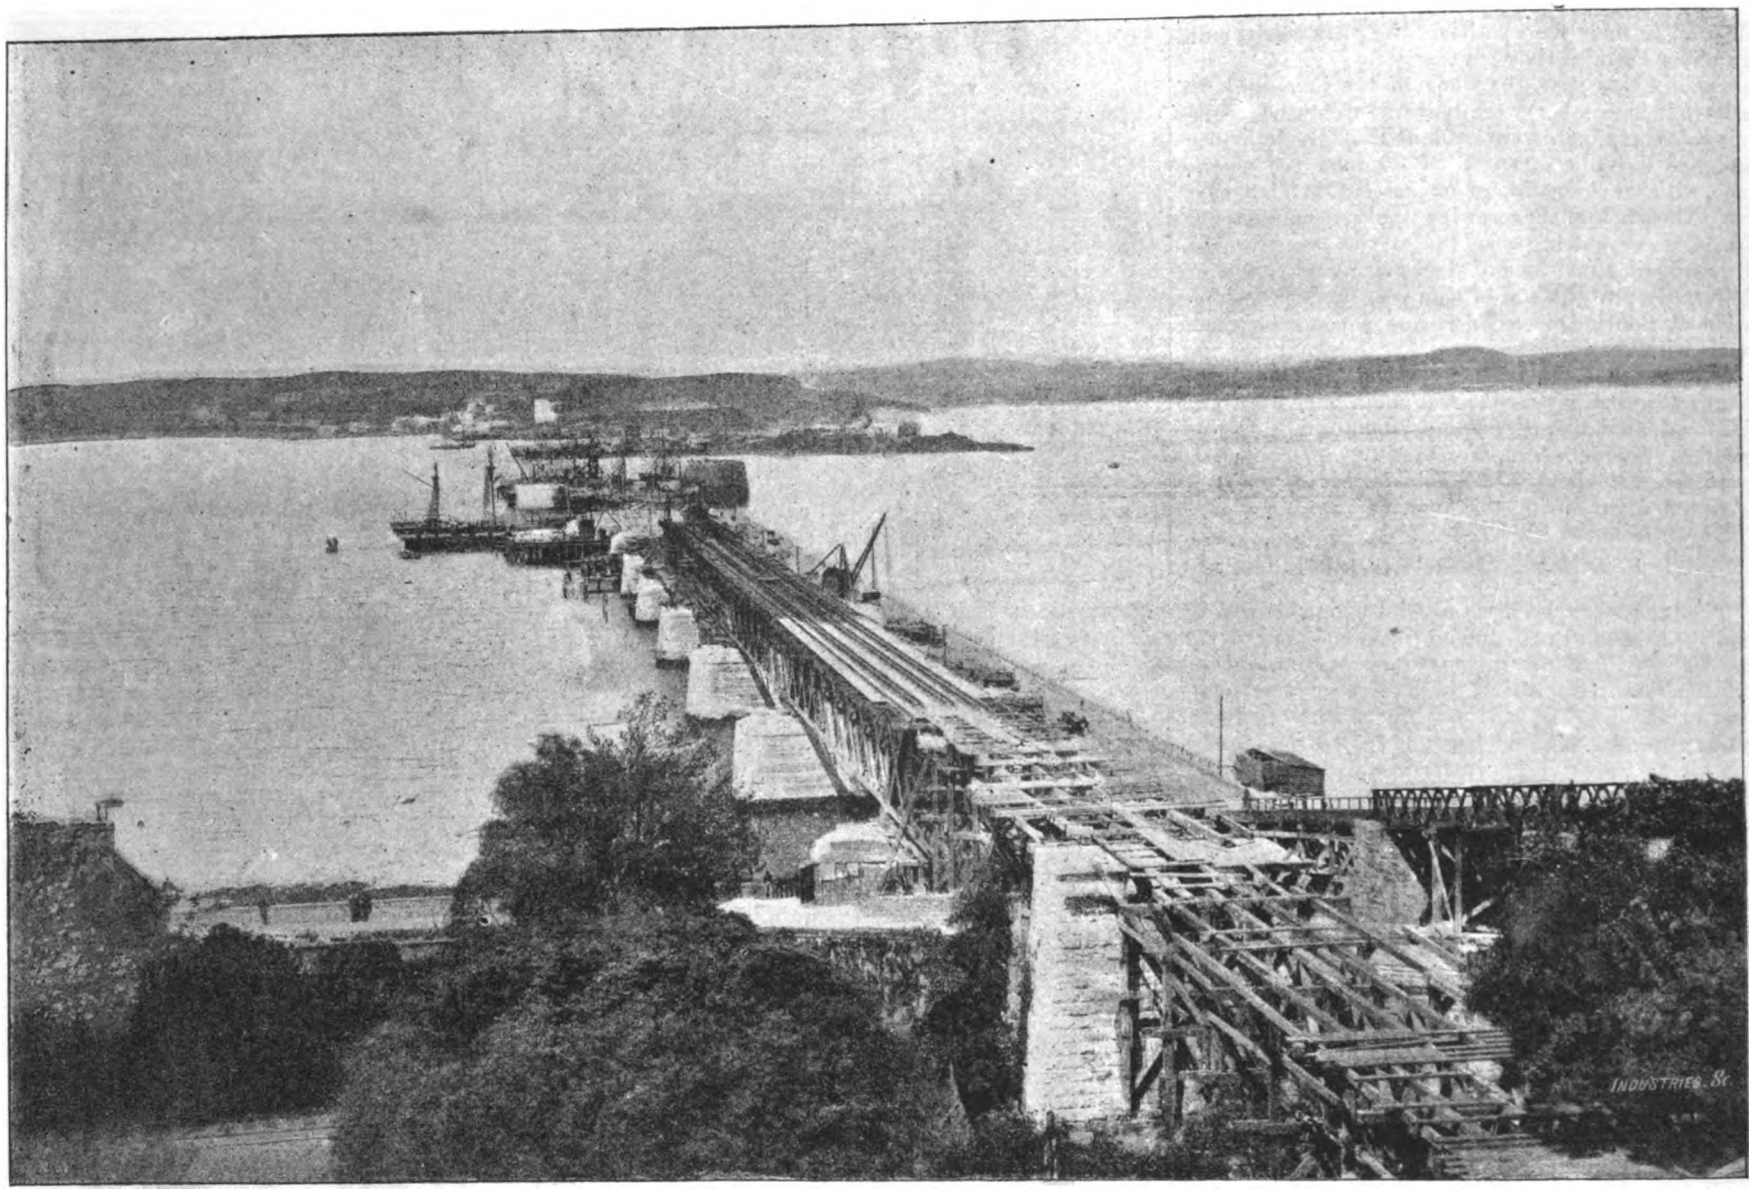

FIG. 21.—VIEW FROM SOUTH SHORE LOOKING NORTH, JUNE 9TH, 1885. SEE PAGE 13.

equally applicable to all the main piers it is now given *in extenso*:—"Above low water, the cylindrical piers, which are 49ft. in diameter at the top, 55ft. at the bottom, and 36ft. high, consist of the strongest masonry, the hearting being flat-bedded Arbroath stone, with both horizontal and vertical bond, and the facing Aberdeen granite, the whole set in two to one cement mortar, and built in the dry, within temporary wrought iron caissons. In the shallow piers, where the rock is stepped, the masonry is carried down to the rock itself, and wrought iron hoops, 36in. by 1¼in., bind the bases of the piers. At the top of all the piers, 18in. by 1½in. hoops, and midway down 18in. by ¾in. hoops, are also built in, and it is believed that these cylindrical masses of masonry are as completely monolithic as can be attained or desired. In each cylindrical pier there are 48 steel bolts, 2½in. in diameter and 24ft. long, to hold down the bed-plates and superstructure of the main spans."

The half-tide caisson for the north-west pier on Inch Garvie was successfully fixed in 1884, and pumped on for the first time in October of that year, and before the close of the year the masonry foundations were well advanced.

On the north side during this year progress had been made with the main piers, the south-west, north-east, and north-west being completed so far as the masonry was concerned, whilst the lower bed-plates of the two latter piers were riveted. Timber staging was erected between the north viaduct piers, and three spans were partially erected before the close of the year, at the level from which lifting commenced.

During 1884 the caissons both for the Queensferry and Inch Garvie piers were pressed forward. The whole of the Queensferry caissons were launched this year, and towed into position, their respective progress being as follows:—The south-west caisson had been sunk to its final depth —62·00 O.D.—through boulder clay, with a bed of mud overlying. This boulder clay, which afforded an excellent foundation, was of so hard a nature that special appliances were devised for dealing with it in the shape of hydraulic spades, the following account of which is taken from Mr. Andrew S. Biggart's paper, read in 1885 before the Institution of Engineers and Shipbuilders in Scotland:—

"Mr. Arrol visited the air-chamber, to see what could be done to hasten the work, and one result was his invention of a hydraulic spade. It consists of a wrought iron cylinder, having a brass casting screwed on to the one end through a stuffing box, on which the shaft of the spade passes, while to the other end is similarly fixed a cap capable of having screwed into it short wrought iron pipes, to vary the length of the spade as required. The spade proper is forged on one end of the shaft or piston rod, while to the other the piston, with the necessary cap leather, is securely fixed. A cock is screwed into the lower casting, communicating with both ends of the cylinder, and to it high pressure water is led through a small flexible hose. Another hose is employed to carry off the exhaust water. When working each spade is served by three men, and the action required is very similar to that in the ordinary hand tool of that name. A working face about 15in. deep is necessary, above which two men (one on either side of the spade) stand, while a third man is stationed immediately behind. (See Fig. 16; also *Industries*, Vol. IV., page 400.) The two men lift the whole machine by a cross-handle, and place the point of the spade on the ground a few inches behind the working face. The third man now opens the cock, and this allows the water to enter the top, which causes an upward movement of the cylinder, until the pipe screwed into the upper end bears against the roof of the chamber and that immediately over a rivet head to prevent it from slipping. The upward movement of the cylinder being thus effectually arrested, the spade is forced into the ground till the piston reaches the end of its stroke, and then, upon reversing the cock, the cylinder falls and sets free its upper end. The clay in front of the spade, being loosened, is finally brought away by the men taking advantage of the leverage of the cylinder which pushes the material off before the spade. What with difficulty was before taken away in pieces about the size of one's hand, was by this spade dug out in lumps so large that they had usually to be re-cut before they could with ease be lifted into the buckets. The whole of the ground within the chamber was accessible to the spade, even to that portion underneath the sloping part of the shoe of the caisson, where it was often held to its work at an angle of about 60 degrees."

Returning to the progress made in 1884 with the Queensferry caissons, by the close of that year that on the south-east was being sunk through the upper layer of mud over the boulder clay, being loaded with some 3,600 tons of concrete. The north-east pier caisson had been successfully launched and towed out to its permanent site, 3,400 tons of concrete having being filled into it, whilst the fourth and last caisson for Queensferry—viz., the north-west—was launched and towed into position.

Progress in the workshops had been steadily maintained during this year, some 5,000 tons of plates and bars having been delivered, of which about 2,000 had been duly manipulated and were ready for erection. The Fife bed-plates, both upper and lower, were finished, and those for Queensferry

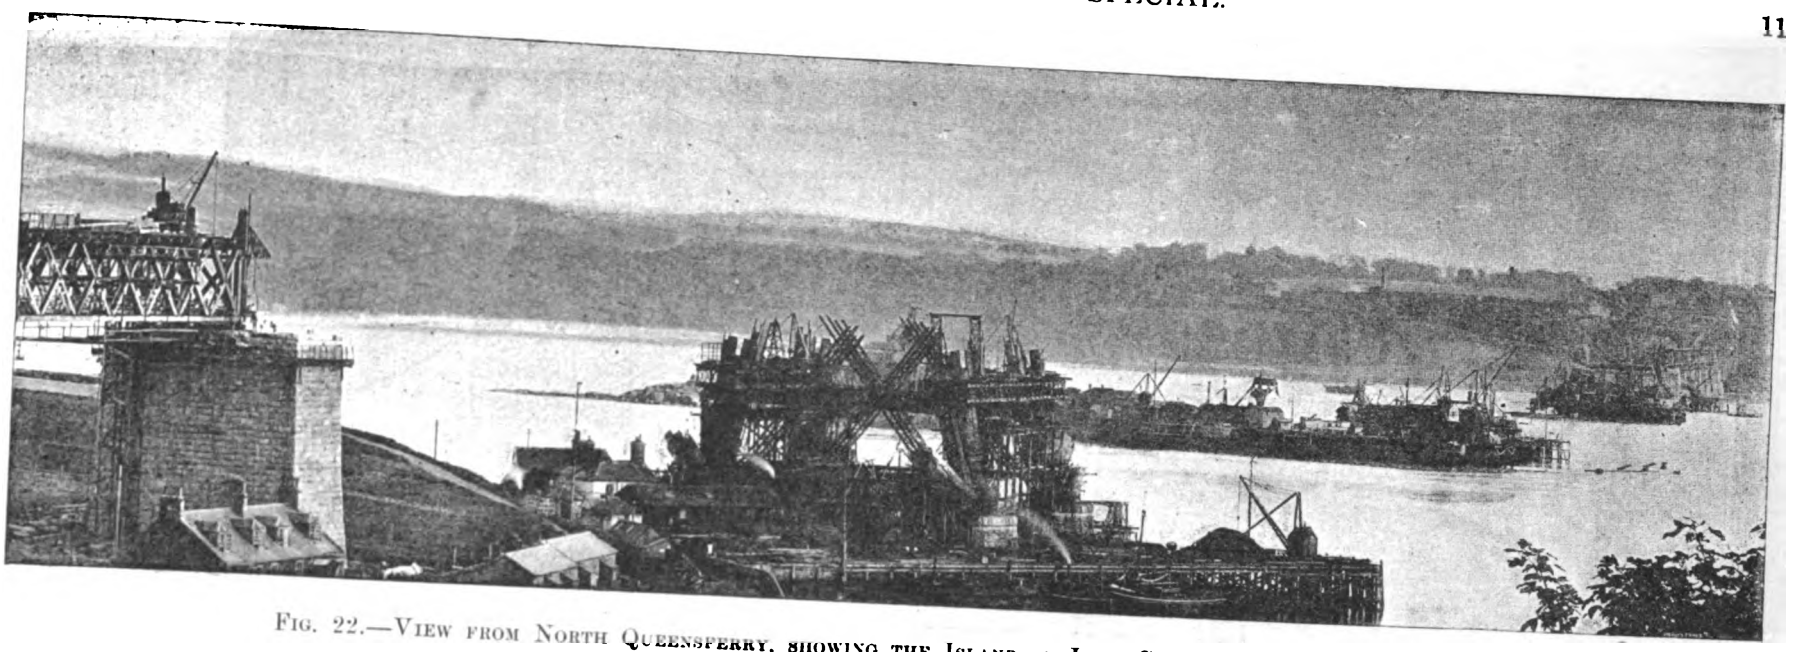

FIG. 22.—VIEW FROM NORTH QUEENSFERRY, SHOWING THE ISLAND OF INCH GARVIE, 1886. SEE PAGE 22.

FIG. 23.—VIEW OF THE WORKS FROM SOUTH QUEENSFERRY, 1886. SEE PAGE 22.

were in hand. A commencement had also been made with the skewbacks (of which more hereafter). (Figs. 18 and 19.) Over 200,000 cubic feet of granite were delivered up to the close of 1884, of which about 150,000 cubic feet were set, whilst some 32,000 cubic yards of concrete and masonry, requiring 8,500 tons of cement, were built. The number of men employed on the undertaking at the close of this year was about 1,900.

PROGRESS DURING 1885.

The close of the year 1885 may be said to finish what may be called the "foundations" or first period of the bridge, the succeeding years, 1886–9, being principally devoted to steel work and erection. The construction of the bridge thus naturally divides itself into two epochs, and we propose at the close of our description of progress in this year (1885) to devote some attention to a general account of the caissons and compressed air work, and generally to conclude our remarks on the first period, in addition to those made in sketching out the progress made year by year, before passing to the second and final part of our description.

Proceeding with the temporary works executed in 1885, and commencing as usual at the south shore, a large additional portion of land was acquired for erecting yards, storing purposes, &c., to the west of the existing shops, and two temporary bridges were thrown across the North British Railway to form connections with the rest of the works. Much interest on the part of visitors attached to these small temporary bridges, on account of the girders being from a portion of the old Tay Bridge. Further additions and extensions were also made in this year to the offices and drill roads, whilst a new drawing loft was erected, and the equipment of plant for dealing with the steel work was largely augmented.

At Inch Garvie further progress was made with the iron staging around the sites of the southern caissons, and additional hydraulic plant was laid down.

On the north shore operations as regards temporary plant were chiefly confined to the erection of timber staging between the main piers, for the subsequent putting together of the steel tubes and bracing.

The permanent work executed at South Queensferry during 1885 on the viaduct piers consisted of the founding and building of No. 9 up to the level 27·00 O.D., so that the first stage in the masonry—*i.e.*, that at which the viaduct girders were built and lifting commenced—was completed during this year for all the south approach viaduct piers. Further progress was made this year with the timber staging between the piers at level 27·00 O.D., and by the close of the autumn seven spans had been erected at this level, and were ready for lifting. A detailed account of the method of lifting the viaduct spans will be found on page 13.

Passing now to the main piers, the chief feature of this year's operations was the unfortunate accident to the caisson for the north-west main pier, which proved a source of much anxiety and trouble to engineers and contractors alike. This caisson, the last one of the group, was floated into position on the 4th of December, 1884, and some 4,000 tons of concrete filled into it, so that, but for an hour or two at high water, it rested on the bed of the Forth. Unhappily, on the night of January 1st, 1885, from causes never clearly ascertained, the caisson tilted over northwards, and settled down into the mud, with the lower end of its upper edge 5ft. below low water mark. Mr. Baker, in lecturing before the Royal Institution on May 20th, 1887, thus describes the accident, and the methods finally adopted in raising the caisson:—"With one of our caissons we unfortunately had an accident and loss of life, which, although it had nothing to do with the sinking of the caisson, as in the Neva Bridge, was indirectly due to the same cause—viz., the softness of the mud bottom. On New Year's Day, 1885, the north-west Queensferry caisson, which had been towed into position and weighted with about 4,000 tons of concrete, stuck in the mud, and, instead of rising with the tide, remained fixed, so that the water flowing over the edge filled the interior. The influx of water caused the caisson to sink further in the mud, especially at the outer edge, and to slide forward and tilt. The contractors determined to raise the skin of the caisson until it came above water level, and then pump out and float the caisson back into position. About three months were occupied in doing this, but when pumping had proceeded a to certain extent the caisson collapsed, owing to the heavy external pressure of the water, and two men were killed. It was necessary then to consider very carefully what had better be done, as the torn caisson was difficult to deal with. Consequently it was determined to case it in 'tubbing' of whole baulks of timber, strutted with ring girders and rakers. This was a very tedious work, as every baulk had to be fitted water-tight to its neighbours by divers. Finally, on October 19th, 1885, or between nine and ten months after the first accident, the caisson, to the relief of every one, was

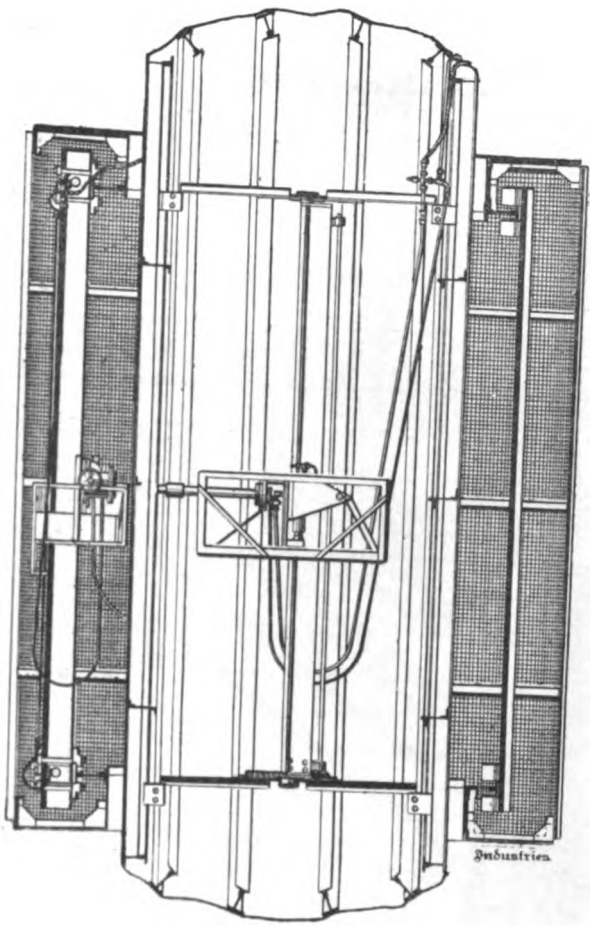
FIGS. 27 AND 28. SEE PAGE 24.



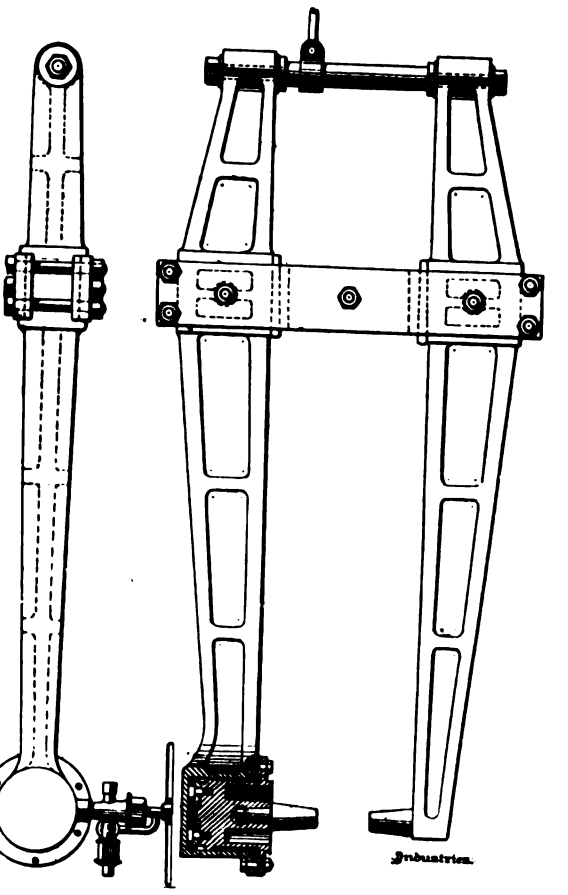
floated into position—this, the last of the main piers, being completed in March, 1886, or almost exactly two years after the first caisson was floated out."

Returning to the three other main piers, excellent progress was made during 1885, for by its close both south-east and south-west had been successfully founded, the masonry pier built and finished, and the lower bed-plates (of which more hereafter) fixed. Similar progress had been made with the north east pier, except that the lower bed-plate on it had not been put in position.

Passing on to Inch Garvie, and examining the permanent work executed there during the year in question, the north-west main pier was founded in a half-tide caisson, and the masonry completed; whilst on both north-east and north-west main piers the lower bed-plates (subsequently described) were fixed. The caisson for the south-east main pier was launched at the commencement of the year, and sunk to its final depth—54·75 O.D. to the cutting edge; the caisson was filled with concrete, and the masonry pier above it built before the close of the year. (See Fig. 20.) The caisson for the south-west main pier (the last built) was launched on May 29th, 1885, reaching its final depth—63·08 O.D. to the cutting edge—on October 2nd in the same year. Concreting and the superincumbent masonry pier were practically completed by the close of this year. A detailed account of the methods of sinking the caissons will be given further on.

On the Fife shore the south-east main pier was successfully founded and built by the close of this year. The foundations of this pier, formed inside a cofferdam of iron segments, occasioned much labour and trouble. The lower bed-plates of both south-east and south-west main piers were duly fixed this year, leaving all this group ready for the erection of the superstructure. Further progress was made with the north abutment, and the erection of the viaduct spans was completed; lifting commenced on August 25th, 1885, and a height of 10ft. was gained and built up before operations at this point were suspended for the winter.

Although the superstructure is dealt with in its entirety in the succeeding part, it may here be stated that during 1885 the two horizontal tubes between the north and south main piers on the Fife



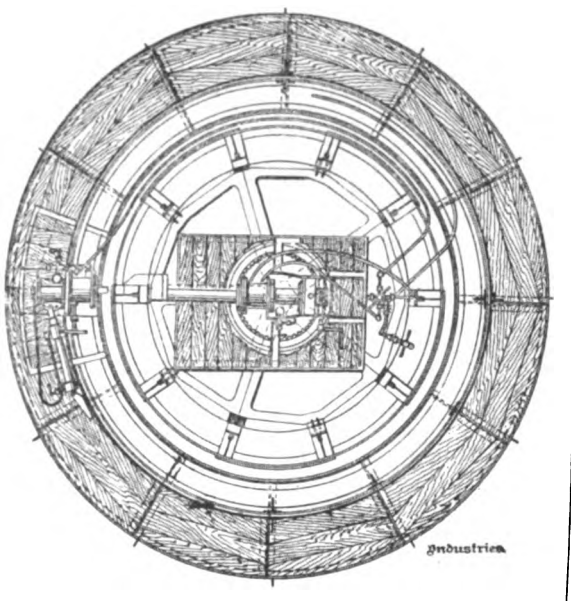


FIG. 31.—PORTABLE HYDRAULIC RIVETER. SEE PAGE 29.

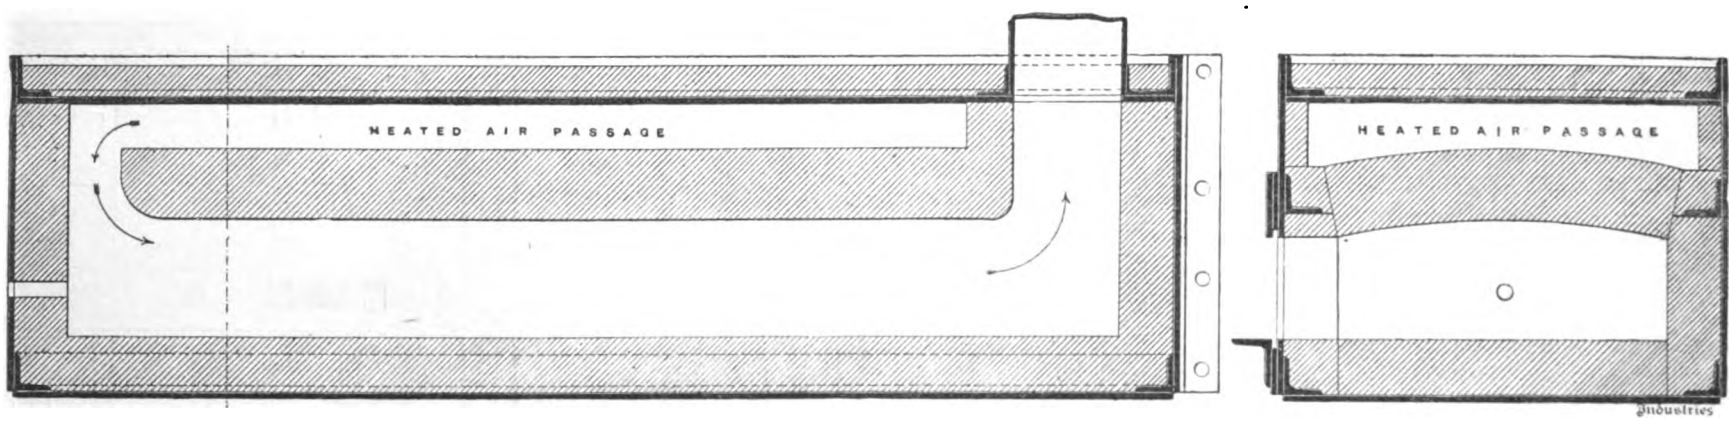
FIGS. 29 AND 30.—ELEVATION AND PLAN OF CAGE FOR RIVETING THE TUBES. SEE PAGE 29.

shore were erected, also a portion of that between the north-west and south-west main piers; whilst on this group a commencement was made in the autumn on the upper bed-plates (of which more hereafter) and also on the skewbacks. (See Figs. 18 and 19.)

Up to the close of this year upwards of 300,000 cubic feet of granite had been delivered, of which about 200,000 cubic feet had been set, whilst some 85,000 cubic yards of rubble masonry and concrete, involving some 15,000 tons of cement, had been built.

The resident engineer for the years 1883–5 was Mr. P. W. Meik, Mem.Inst.C.E. Though the steel work is dealt with subsequently *in extenso*, it may be added that up to the period reached, all the twelve skewbacks were in hand; two for Fife were under erection *in situ*, and the two remaining ones were completed on the drill roads, whilst the Queensferry group were well advanced and those for Inch Garvie in hand. 2,300 lineal feet of 12ft. tubes and 2,000 lineal feet of 8ft. tubes, also 3,200 lineal feet of ties, were drilled, and good progress made with the top junctions. Over 18,000 tons of steel had been delivered, and the average number of hands employed was about 2,000.

Fig. 21, taken from the south shore looking north, gives a general idea of the progress on the date on which it was taken, June 9th, 1885.



Before closing this portion of our description, which refers chiefly to the foundations, and which comprises the period 1883–5, both years inclusive, we proceed to supplement our remarks on the progress by concise accounts of the lifting of the viaduct spans, the caissons and compressed air plant, and the material employed during this period.

THE LIFTING OF THE VIADUCT SPANS.—The whole of the spans were lifted simultaneously as soon as the riveting was completed on them. Steel cross-beams, with pairs of hydraulic jacks, were placed under the ends of the girders over the piers, and a stage surrounding the piers was suspended from the main girders. From this platform the men in charge of the rams conducted the operations of lifting and blocking up the girders, and the masons afterwards completed the stonework in the vacant spaces. The materials for the piers were first raised in trucks by a steam hoist on the jetty to a tramway laid on beams between the bottom members of the girders, and afterwards lowered into position by winches over each pier, these winches being driver by running ropes from engines on the girders at alternate piers. The southern viaduct spans have a total length of 1,680ft., and weigh altogether about 2,000 tons.

The hydraulic jacks referred to above were 15in. in diameter, with water pressure of 34cwt. per square inch, supplied by steam pumps. Forty-eight hours were allowed for the proper setting of the cement between the finishing of the courses in one lift and the commencement of the lifting for the next. The average rate of progress attained in lifting and building was about 10ft. per month. The actual raising of the girders occupied on an average about two hours for each lift.

THE CAISSONS.—Of the four Queensferry caissons the deepest was 72ft.—*i.e.*, the cutting edge was 89ft. below high water. The diameter in each case was 70ft. at the base. Seven feet above the cutting edge was a floor of iron plating, which formed the air chamber roof. Above the floor the caisson was double-skinned, angle irons for stiffly bracing it together being introduced between the skins. In the outer skin the lower plates were made to lap outside the upper

ones, so that the joints should cause no obstruction in sinking. The outer skin had a batter of 1 in 46, extending to 27ft. above the cutting edge; from this point to within 18ft. of the top the sides were vertical, and then tapered quickly to the top, which had a diameter of 60ft. The cutting edge was formed by a steel plate 1in. thick and 18in. deep, the shoe being firmly stiffened by stout diaphragms spaced 4ft. apart. Four main girders, 18ft. deep, and a series of cross girders, 3ft. in depth, were placed above the floor, and supported it. The four main girders were connected at each end with both skins, by means of bulkheads between the skins, to which they were riveted. Previous to launching some concrete was filled into the shoes to give increased stability. When towed into position at the end of the jetty, piles were driven in round each caisson, and it was further secured with mooring chains. Concrete was then filled in until the caisson sank on to the bed of the river. Each caisson was provided with three shafts, 3ft. 6in. in diameter; one was furnished with a ladder for the men, and the two remaining ones were for the buckets containing the "spoil"; all three were of course fitted with air locks, which were on the surface.

The lock for the men consisted of an outer tube enclosing the upper end of the shaft, an air-tight door being fitted in each and lined with india-rubber facings. A cock was used for admitting compressed air from the shaft into the lock, and a similar communication between the lock and the outer atmosphere was also provided. On entering the annular space around the inner tube, the door in the latter was found closed. The outer door was then shut, and pressure gradually admitted until that in the lock was equal to the pressure in the vertical shaft. The inner door could then be opened, and the descent made; in ascending the process was reversed. The mud was removed by means of ejector pipes, having been previously mixed with water introduced through a supply pipe, the air pressure in the chamber forcing the mud through the ejectors. "It was found that the mud scaled the caissons," says Mr. Baker, in lecturing, in May, 1887, before the Royal Institution, "so that a pressure of air considerably in excess of that of the water outside could be kept up, and it was unnecessary to vary the pressure according to the height of the tide.

"In working through this soft mud, both intelligence and courage were called for on the part of the men, and it is a pleasure and duty for me to say that the Italians and Belgians engaged on the work were never found wanting in those qualifications. There was always a chance of the caisson sinking suddenly or irregularly, and imprisoning some of the men, and indeed on one occasion a few men were buried up to their chins in the mud, and on another the caisson gave a sudden drop of 7ft. Happily no serious accident happened, although I confess that I felt a little apprehensive myself, as I was familiar with the details of an accident with a similar caisson sunk in the bed of the Neva, at St. Petersburg, in 1876. In that case the wet mud rose rapidly in the working chamber when the caisson sank suddenly 18in. one day, and of the twenty-eight in the chambers nine remained imprisoned. Of these two managed to get their heads into the shaft of access, and were taken out alive after twenty-eight hours, and the remaining seven were smothered in the mud. It was nearly a year before sinking was renewed.

"Again, in 1877, one of the air locks suddenly gave way, and of the men then in the chamber three escaped uninjured; nine were blown out by the rush of air, and, falling into the water and on craft, were mortally injured, whilst twenty were smothered in the caisson. It was thirteen months before the chamber was accessible, and then the vitiated atmosphere in the charnel house below rendered it very difficult to work. Happily we had no such experiences at the Forth."

The excavation of the boulder clay underlying the soft silt was performed by means of hydraulic spades, already described in detail. (See Fig. 16 and page 10.) The best progress made in excavating this material was about 1ft. per day of 24 hours, over the whole area of the caisson, with 27 men and four hydraulic spades, filling a bucket every five minutes.

This is equivalent to a digging power of 35 cubic yards per spade, and of 5 cubic yards per man, for each day of 24 hours. The men worked in six-hour shifts, and excavation was carried on continuously day and night, each squad performing two shifts. The south-west caisson was sunk 39ft. in 99 days, the south-east caisson 37ft. in 72 days, whilst in the same number of days (72) the north-east caisson was carried down through 43ft.

"A matter of the utmost importance, and one requiring vigilant watchfulness, was the sinking of the caisson vertically. If not in its true position when operations were commenced, it was so guided as to bring it to the correct place when down. This was generally accomplished by tilting its top in the direction opposite to that in which it was intended to move it, and, sinking being continued while so tilted, the lower edge gradually approached its true position. On this being attained the whole caisson was righted, and, if still true, was sunk vertically till it reached the proper depth. Another way of effecting the same purpose was to tilt the caisson as before but immediately afterwards to right it, when it was found to have moved through a certain distance sideways, and that in the direction required, owing to the side first tilted having pressed against the lower and harder ground, thus causing the caisson when righting to move a little in the one direction. A secondary assistance was to place heavy timbers at an angle against the top of the shoe. These timbers were made to bear against the ground, so that when the caisson was subsiding their tendency was to push it from them, and thus help to bring it back to its true place."

We pass on now to the caissons for Inch Garvie south-west and south-east main piers (See Fig. 20); but little difference is to be noted in their construction, except that the lower half of the shoes had supporting brackets instead of sloping shoe plates, thus stiffening the cutting edge at the bottom and permitting readier access to the rock beneath. The sides of the caissons were built vertical until within 24ft. of the top, when there was a quick batter from 70ft. to 60ft. diameter at the top. This upper part, more-

over, had only one skin, which was stiffened by circular girders and a brick lining 2ft. 4in. thick.

The soundings taken previously at the sites of the Inch Garvie southern main piers present some features of interest. A timber raft, with a diameter of 69ft. 8in., was towed out, and moored over the site of the pier, its position being taken by means of two theodolites on the island sighting on to the centre of the raft, and in the case of one of them on to a point on the circumference also. A circular road was laid on the outer edge of the raft, on which travelled a light carriage, supporting the lifting and lowering drum. The wire finally adopted for sounding was of steel and $\frac{1}{10}$in. diameter. Copper wire was tried, but abandoned. The "sinkers" were a source of considerable trouble. The strong tide running off Inch Garvie necessitated the adoption of heavy sinkers, and, even with all the care exercised, it was impossible to avoid their occasional loss. The type eventually adopted was a 10ft. bar of iron $\frac{3}{8}$in. diameter, with a lead weight cast around its centre, the whole weighing about 60lb. Care had, of course, to be exercised that the sinkers did not lie down at the bottom, and augment the reading by an erroneous 10ft. After a variety of experiments, brass tallies, secured by string to the sounding wire, were adopted for giving the reading. The raft was held in position by four moorings, and had four crabs on board to admit of its movement. The diameter of the caissons was 70ft. Soundings were, however, taken for a radius of 70ft. from the centre of each caisson, thus affording not only an accurate plan of the bed of the Forth beneath the caissons, but also for 35ft. outside all round. The raft was marked at every foot of its circumference, and readings were taken at every foot inside the caisson area, and at every 5ft. outside that limit. A tide gauge on Inch Garvie was read every five minutes, so that, by similarly noting

the time of the readings from the raft, they could be subsequently reduced to Ordnance level.

Operations were carried on as much as possible at slack water, as the strength of current was very considerable at other times. The rate of progress was estimated at about two soundings per minute, and in all some 3,000 soundings were taken. These, after being carefully plotted, were utilised in the construction of models of the bed of the river at the caisson sites. Wires were cut off to heights corresponding to the different readings, and fixed upright into a stout board. Cement was then filled in so as just to cover the heads of the wires. By these means an exact reproduction of the rock to the south of Inch Garvie was obtained on a reduced scale, and afforded valuable and ready means of seeing at a glance the slope on which the caissons had to rest when first sunk into the respective positions. Fig. 20 shows how this difficulty was eventually met and overcome. The lower portion of the rock was levelled up by divers with bags filled with sand and concrete, so that the cutting edge of the caisson when sunk rested on a level surface. Excavation of the rock was then proceeded with at the north end, and the sand bags gradually cut away as the caisson descended. Rock drills, driven by air of 70lb. per square inch, led into the caissons by special pipes, were employed for this purpose. (See Fig. 17.) The rate of excavation of the rock at Inch Garvie averaged some 18 cubic yards per 24 hours, exclusive of the removal of any sand.

In the south-west caisson the highest point of the rock was 60ft. below high water and the lowest 74ft. below the same level; and in the south-east caisson these figures were 47ft. and 67ft. respectively. The removal of the rock was practically a matter of ordinary quarrying, with the additional necessity of working in compressed air. Dynamite fired by electricity was employed for blasting purposes. The maximum pressure of high tide in these caissons was about 33lb. per square inch above the atmosphere.

We will turn now to a general consideration of compressed air, its effect on the workers, and the more salient features in regard to its employment. We may point out that the result produced varies with each person, the usual sensation being one of considerable pain in the ears, owing to inequality of pressure inside and outside the tympanum or drum. Numerous curious phenomena were apparent in the air chamber. Whistling became impossible, and bottles of effervescing drinks opened flat and insipid, the pressure of the atmosphere being equal to that previously forced into them in manufacture. So long as the pressure did not exceed some 18lb. no ill effects were felt by the workers. Above this pressure, more especially when excavating mud, severe pains in the legs and arms, accompanied in the worst cases by a kind of paralytic stroke, were experienced, generally after leaving the caisson.

Two interesting incidents in connection with the caissons may be quoted in Mr. Baker's own words:—"Probably the most astonished visitors were some salmon, who, attracted by the commotion in the water caused by the escape of the compressed air under the edge of the caisson, found themselves in the electric-lighted chamber. When in the chamber, the only notice of this escape of large volumes of air was the sudden prevalence of a dense fog, but outside a huge wave of aërated water would rise above the level of the sea, and a general effect prevailed of something terrible going on below. No doubt the salmon thought they had come to a cascade turned upside down, and, following their instinct of heading up it, met their fate. Another astonished visitor was a gentleman who took a flat-sided spirit flask with him into the caisson and emptied it when down below. Of course the bottle became filled with compressed air, and it exploded when passing through the air-lock into the normal atmospheric pressure, the pressure in the bottle being 33lb. per square inch." All the air chambers were lighted by electricity, those at Queensferry having from 16 to 20 incandescent

Digitized by Google

Swan lamps of 20 candle-power each, the current being supplied by a Siemens dynamo actuated by an 8 h.p. engine. The Inch Garvie caissons were lighted by arc lights, incandescent lamps being too fragile to withstand the blasting. Three arc lights were employed, each having 1,200 candle-power. A Crompton compound dynamo, driven by a 14 h.p. engine, supplied the current. Photographs were taken in the caissons (see Figs. 16 and 17), a lighting power of 6,000 candles being employed, and an exposure of as much as fifteen minutes being given in some cases. The fog at all times present in the caissons militated against successful photography under such novel circumstances. (For a full account of these experiments, see *Industries*, Vol. IV., page 400.) The sinking of the deep caissons was sublet to Messrs. Croiseau. They employed Italian workmen, having previous experience of compressed air.

THE MATERIALS EMPLOYED IN THE CONSTRUCTION OF THE MASONRY OF THE BRIDGE.—The main and viaduct piers were built of granite, and headed with concrete and Arbroath rubble. The caissons were filled with concrete. The granite was almost entirely from the Aberdeen quarries, being brought to the site of the bridge by water. The class of work put into the piers is known as "rock-faced," the imposts, string courses, and copings being "dressed." The material was shaped and prepared at the quarries previous to shipment by Messrs. Fyfe, of Aberdeen. The concrete filling the caissons consisted of 27 cubic feet of broken whinstone, 7 cubic feet of sand, and 5½ cubic feet of cement. The crushing strength of the concrete was about 50 tons per square foot. Cement mortar, composed of two parts of sand to one of cement, was employed. The cement employed was the best quality of Portland cement, ground so fine that the residue on a sieve 2,500 meshes to the square inch (equal to 50 per lineal inch) did not exceed 5 per cent. by weight. The neat cement (gauged with a proper proportion of water) was specified not to set in less than one hour during any season of the year, whilst when formed into briquettes it was required to bear after four days, without breaking, a tensile stress of 300lb. to the square inch of section, and after seven days a stress of 400lb. to the square inch of section. The cement was further required, after gauging with three times its weight of dry sand, which would pass through a sieve 400 meshes to the square inch but would be retained upon one of 900 meshes, and mixed with the proper proportion of water, to be made into briquettes, which, having been kept in a damp atmosphere for 24 hours, and then immersed in water for 28 days, to stand without fracture a tensile stress of 170lb. per square inch of section. The cement weighed from 112lb. to 116lb. per bushel, and about 21,000 tons were used in the entire undertaking, being supplied by Messrs. Hilton, Anderson, & Co., and J. Bazley White & Co. The total amount of granite was 707,000 cubic feet, whilst 117,000 cubic yards of masonry and concrete were set. The quantity of timber used in the entire undertaking for temporary purposes, stages, jetties, &c., is estimated at 1,000,000 cubic feet.

PROGRESS DURING 1886.

THE SUPERSTRUCTURE.

The temporary work executed during 1886 consisted mainly of appliances to aid in the erection of the superstructure, and under the subsequent heading of plant a detailed description, with illustrations, will be found of the more important. Suffice it, therefore, to briefly point out that during this year hydraulic apparatus for riveting and lifting; powerful and specially designed machines for riveting the 8ft. and 12ft. tubes; goliath cranes, hoists, and steam winches; compressors, accumulators, and rams for high pressure riveting, were constructed, along with other appliances too numerous to catalogue, to aid in the erection of the steel work.

To dispose of the masonry work executed in this year, before considering in detail the erection of the superstructure, which necessarily forms the leading

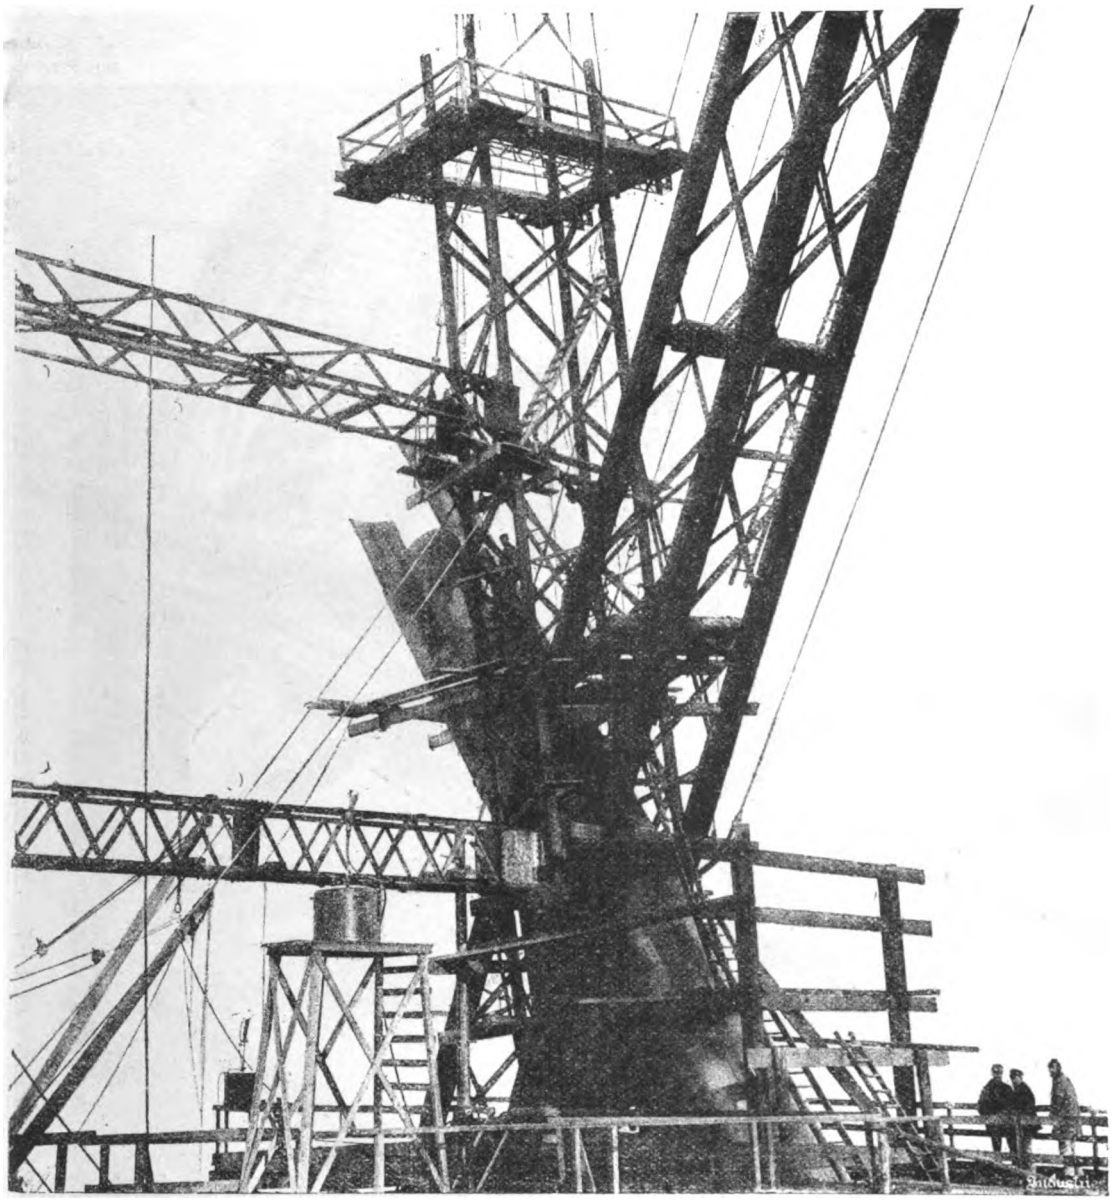

FIG. 52.—CROSSING OF TIE 1 AND STRUT 1, AND TEMPORARY VERTICAL COLUMN, 1888. SEE PAGE 30.

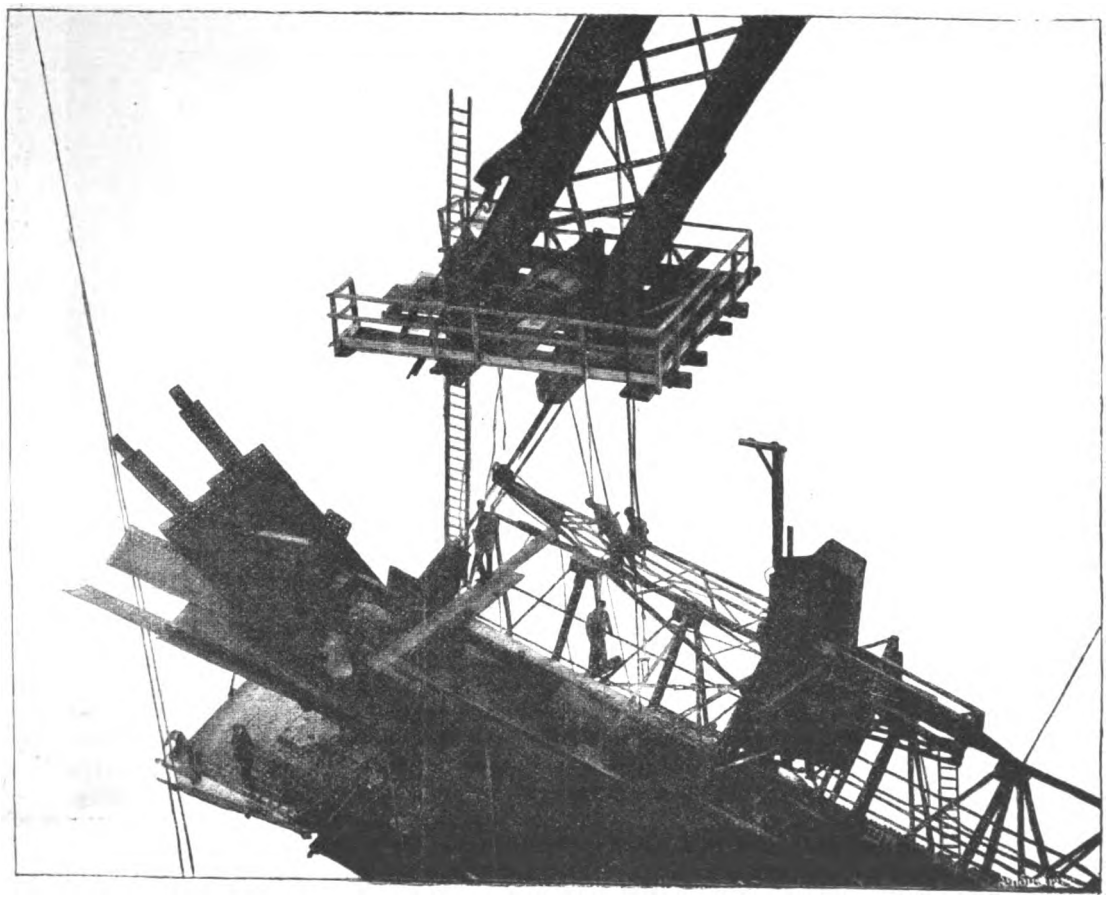

FIG. 53.—JUNCTION OF STRUT 2 AND TIE 1 WITH BOTTOM MEMBER, QUEENSFERRY, N.E., 1888. SEE PAGE 30

characteristic of this and the three succeeding years, we may briefly state that, on the south shore, Queensferry north-west main pier was completed, the viaduct piers raised to about half their total height, and the south abutment founded; whilst, on the north side, the cantilever end pier and the north approach viaduct piers were carried up to within a few feet of their ultimate height; and that, by the close of the year, upwards of 450,000 cubic feet of granite had been delivered, of which some 410,000 had been set, whilst over 100,000 cubic yards of masonry and concrete work had been built.

We pass on to the consideration of the steel work (See Figs. 22 and 23), and we will commence at the south end of the bridge; the lower bed-plates (of which more hereafter) of the north-east and north-west main piers were fixed, and the upper bed-plates (of which more again) of all four main piers were erected and riveted. The skewbacks (See subsequent detailed account), with horizontal tubes and bracing girders connecting them, were practically complete, and a commencement had been made with the erection and riveting of the bottom members. The vertical columns and diagonal struts had been erected for nearly one-third of their total height by means of an erecting platform (a description of which, and methods of raising, will be given later), and in all nearly 2,000 tons of tubes and lattice-work had been riveted up.

Turning now to Inch Garvie, the lower bed-plates on the south-east and south-west main piers were riveted and lowered into position during this year, whilst the upper bed-plates of the whole group were erected and riveted up; the four skewbacks, together with the horizontal tubes and bracing girders, were complete, and a commencement was made with vertical columns, diagonal struts, and bottom members, as also with the temporary erecting platform. Riveting on the tubes and girders was completed on over 2,000 tons of material.

At North Queensferry the progress which was made by the end of 1886 was as follows:—The whole of the bed-plates and skewbacks were completed and the riveting up of the latter about two-thirds finished; the vertical columns and diagonal struts had been raised to fully half the total height; and a commencement made with the erection of the bottom members. Upwards of 2,000 tons of steel work was riveted. (See Fig. 24.) In addition to the amount of work erected in this year, as described, progress had been carried on in the workshops, with the result that by the end of 1886 the internal viaduct was well in hand, as far as drilling and fitting were concerned, and the junctions of bay 1, were considerably advanced, in addition to further lengths of the bottom member prepared for erection. Over 33,000 tons of steel were delivered by the close of this year, and the average number of hands employed was approximately 3,000.

THE BED-PLATES AND SKEWBACKS.

The lower bed-plates, having been fitted and drilled in the shops, were put together over the masonry piers upon iron supports, sufficiently high to enable the hydraulic riveting to be proceeded with. The lower bed-plates were then lowered into position over the heads of the foundation bolts, and they will ultimately transmit to the masonry the whole weight of the superstructure, rolling load, &c. (See Figs. 25 and 26.) The surfaces of the lower bed-plates were ground smooth by emery wheels in special machinery designed to travel over them, and were subsequently coated with crude petroleum before the upper bed-plates were laid on them. These latter were fitted, erected, and riveted in the same manner as those below them, and for similar reasons. The riveting of the bed-plates (See Figs. 25 and 26) was performed by two longitudinal girders, connected together, one on each side of the work, each being provided with a ram travelling along it for closing the plates.

"The skewbacks" (See Figs. 18 and 19), says Mr. A. S. Biggart, in his paper read, on January 24th, 1888, before the Institution of Engineers and Shipbuilders in Scotland, "are the most complicated parts of the entire structure, the difficulties at this point arising

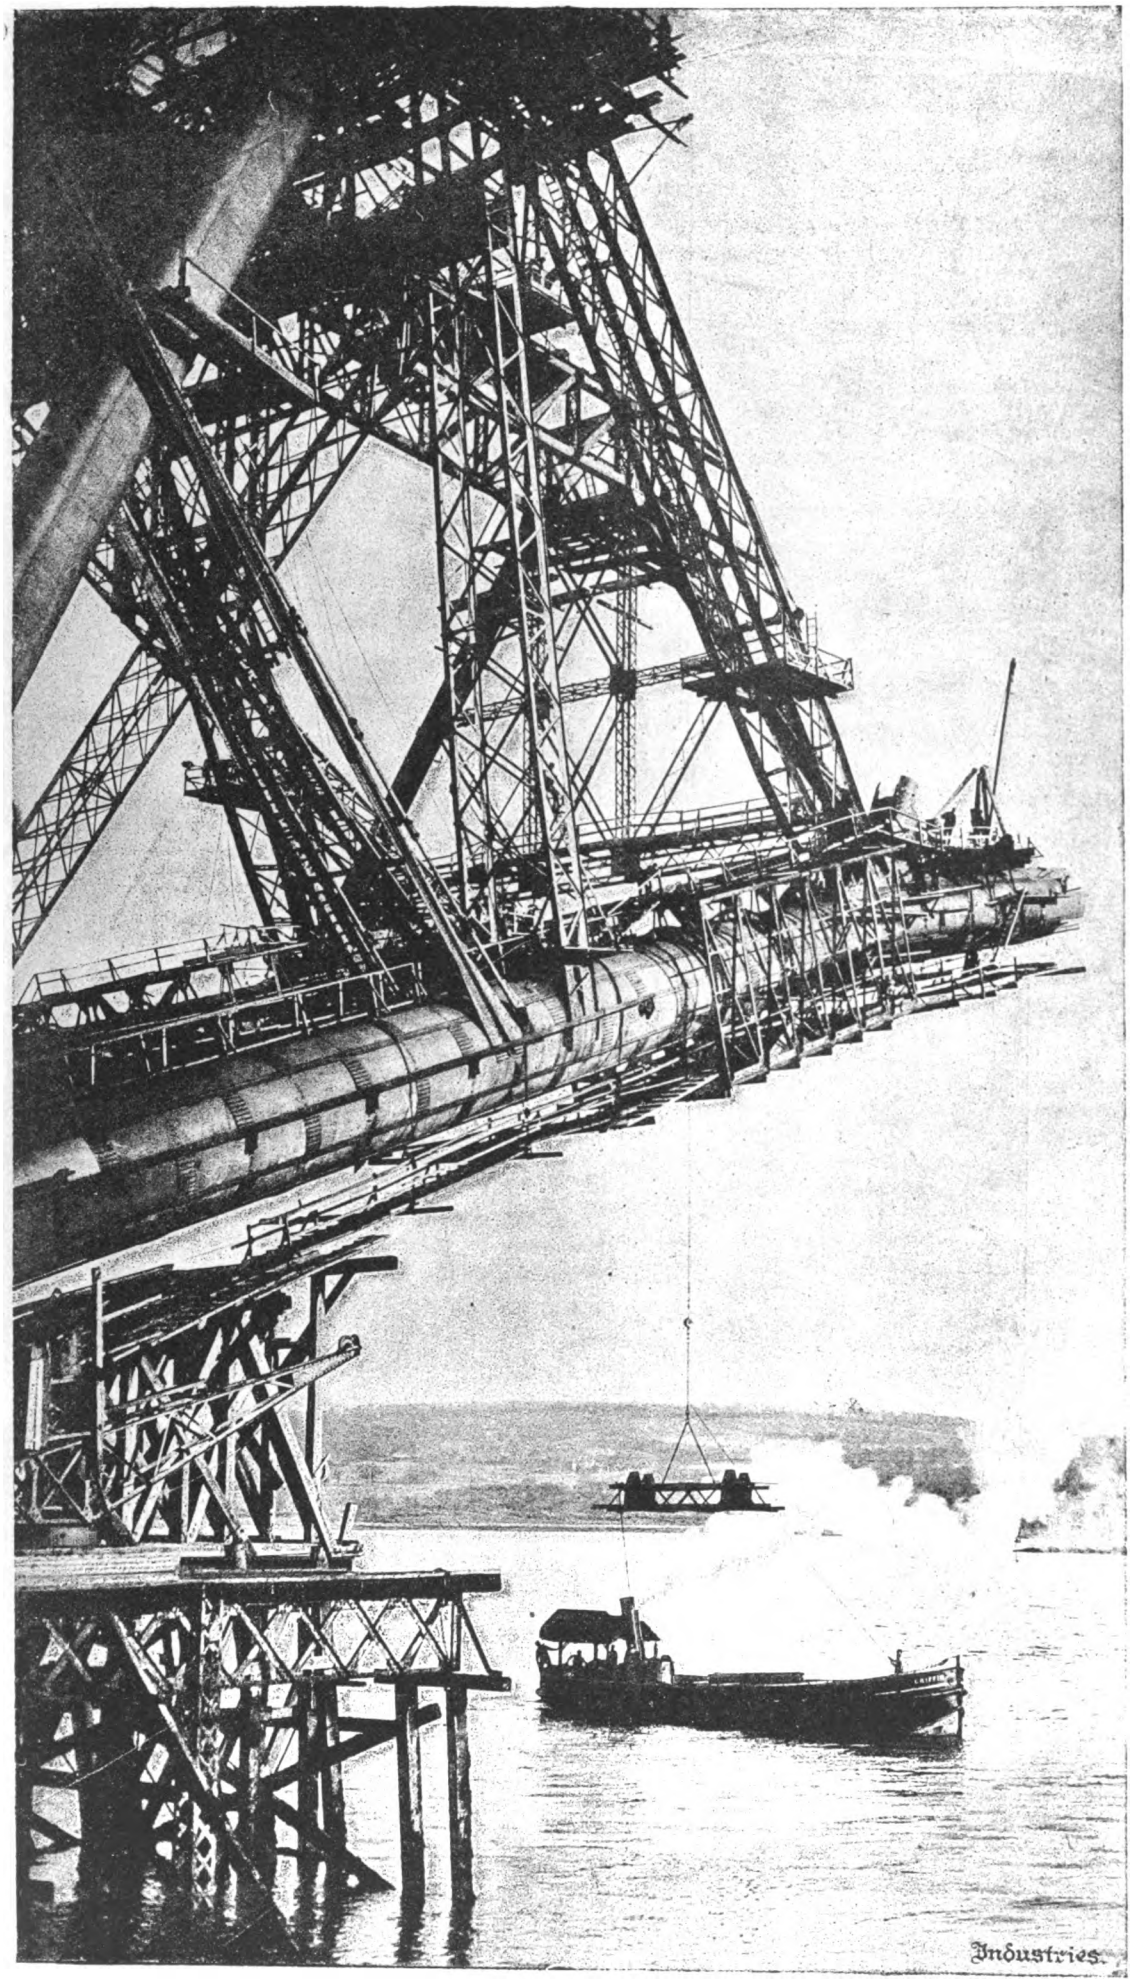

FIG. 55.—SOUTH CANTILEVER OF THE FIFE MAIN PIER, 1888. SEE PAGE 30.

mostly on account of the various angles at which the different parts lie in relation to one another and to the skewback. Each skewback may be looked upon as being either the starting point or termination of five separate tubes and five distinct box girders. All these members are so joined to it as to transfer into or through the various parts of the skewback the stresses of each member. The skewbacks also act as the upper or sliding bed-plates, on which some of the movements of the piers and cantilevers, due to expansion and contraction, take place. The sliding surface is the lowest course of several layers of steel plates, which form the base of the skewback (described already as the "upper bed-plate"). On the top of these bed-plates a series of longitudinal girders are riveted, while in section these girders are crossed at short intervals by one central and two smaller side diaphragms. Small stamped diaphragms are also placed between the longitudinal girders immediately under the main ones. Between the centre and side diaphragms, and beyond the latter, are riveted four longitudinal lines of plates, as also a top plate, all of which merge into the horizontal and cantilever tubes at the opposite ends of the skewback. To the inner lines of the plates the sides of the two small 8ft. tubes are riveted. These also serve as part of the connection to the vertical column. Gusset plates and angles are principally used in making the connections of the girders to the skewbacks."

The riveting up of the skewbacks required special appliances, and was a task involving much ingenuity and time. In the interior portions riveting by hand was altogether impracticable, owing to lack of space, and the ordinary rams were also, for a like reason, unavailable. They were dealt with by special rams 4in. in diameter, one acting as the holder-up, the other as the snap. (See Fig. 19.) The water pressure on the works of 1,000lb. per square inch was increased to about 6,000lb. per square inch for the service of these rams by special intensifiers with rams 4in. and 10in. diameter. (See Figs. 27 and 28.) The riveters worked in spaces as small as 2ft. 6in. long by 15in. high by 15in. broad, access to this limited area being still further reduced by a 4in. angle running around the top. The timber backing to the rams required careful management. Working under such conditions, with constant shifting from cell to cell, a riveting squad could close about 100 rivets per day.

PLATFORMS FOR ERECTION PURPOSES.

The erection of the vertical columns was performed by means of a platform supported by the columns themselves and carried up with them. (See Fig. 25; also Figs. 19 and 24.) The principal conditions laid down with reference to the erection of the central portions of the double cantilevers were, as stated by Mr. F. E. Cooper, M.I.C.E., Resident Engineer of the Forth Bridge from 1885 to 1890, in his paper before the Iron and Steel Institute in 1888:—

"1. That in order that the men should be able to work at any height in as great security and comfort as if on the level of the ground, platforms or scaffolding of considerable area should be provided.

"2. That the raising into position of the several parts of the structure should be as little as possible interrupted by wind, the ordinary derrick cranes not being then considered applicable.

"3. That the weight of the platforms and apparatus should not much exceed 400 tons.

"4. That the connections forming the supports should not bring excessive strains upon any part of the permanent structure.

"5. That no rams of the lifting apparatus should have to exert a lifting force of much more than 100 tons.

"6. That the platforms should form ultimately stages for building the top members over the piers.

"7. That, for the sake of economy, material forming part of the permanent structure should be made use of temporarily as much as possible."

The platforms were two in number, one on each side of the axis of the bridge. Each consisted of two parallel lattice girders (placed 18ft. 6in. apart), with all bracing required and a timber floor, holes being of course left for the vertical columns of the bridge. The platforms were 20ft. wide and 200ft. long at Fife and Queensferry, that at Garvie being 350ft. in length, owing to the greater distance the main piers were apart in the line of the bridge at that place. The longitudinal girders formed subsequently part of the permanent ties of the structure, thus effecting a saving of material. The main

Digitized by Google

girders carrying the platform were in turn supported by short cross girders (See Figs. 36 and 37), inside the vertical tubes of the structure.

The following account of the method of raising was given by Mr. E. M. Wood, in his paper before the Institution of Mechanical Engineers in 1887:—

"The lifting gear for raising the erecting platforms consists of a pair of plate frames, one below the other, fixed inside each 12ft. pier-column, by pins passing through the wings of the frames and the ribs of the column. The lower frame supports the hydraulic lifting press; and upon the upper rests the through box-girder cross-beam, at right angles to the length of the bridge, passing through voids in the columns, where plates are temporarily left out for this purpose. These cross-beams support lattice-girders in pairs, one on each side of the column, which extend a little more than the full length of the side of the quadrangle formed by the piers. Upon the top of all comes the main deck, furnished with gantries, cranes, oil-heated rivet-furnaces, &c., complete in all respects for carrying on the chief operations of erection. On the bottom level of the girders is a lower deck, with the ends housed in to form temporary shelters for the men. The box and other girders are built up of parts which will eventually be used in the permanent structure. Communication between the level of the jetty and the platforms is made by hoists, drawn up between wire-rope guides by the winding engine on the level of the jetty, which lifts the material by wire ropes to the platform; safety clutches are attached to each cage, for seizing the guide ropes in case the hauling gear were to give way. During lifting operations, access to the platforms is gained by ladders laid up the cross-bracing between the main columns over the piers.

"The process of raising the platforms is as follows: Water-pressure at about 30cwt. per square inch is conveyed from pumps on the jetty to the lifting presses by wrought iron piping taken up the inside of the columns, and is turned into the cylinder, lifting the load off the series of pins in the top frame. The pins are then withdrawn, and the ram lifts the box-girder, carrying with it the loose frame, until it comes oppposite the next series of holes in the ribs of the columns, into which the pins are then inserted; the pressure is released, and the box-girder again rests upon the upper frame. In the return stroke the ram, hanging by its shoulders from the upper frame, by means of its piston form now hauls up the lower frame, from which the pins have been withdrawn; and when this has been re-pinned, it is ready to support the press for another upward stroke. By this means the platforms have been gradually raised, generally through lifts of 16ft. at a time, until arrival at the summit. On their way up they have been utilised for building the tubular cross-braces and other work; and at the present time those at the southern and northern piers form the stage for erecting the top members between the heads of the main columns.

"In building the pieces together, they are connected by service bolts, until the hydraulic riveters are brought into action."

PROGRESS DURING 1887.

The temporary work executed in this year was almost wholly with reference to the erection. In addition to numerous stagings and minor platforms, shelters at each of the three piers, capable of accommodating 200 men during meals or bad weather, were provided. During this year four out of six specially designed steam cranes for the erection of the top members, and the struts and ties, were provided. (See Figs. 57 and 58.) These cranes were attached to the top members, and as they gradually followed the work throughout erection they commanded the work in a most advantageous manner. (See subsequent description.) Much other minor plant was added this year—notably hydraulic rams, &c., but they were not of such special interest as to merit a detailed description here.

Passing on now to the masonry executed during 1887, we may briefly state that on the south side the viaduct piers were raised to their full height and completed, the south cantilever pier carried up to about rail-level, and the south abutment raised to the springing of the arches. On the Fife shore the north approach viaduct piers were also carried up to full height and finished, the completion of the north abutment being similarly effected, whilst the north cantilever pier was raised some 15ft. higher than that which corresponded to it on the south side. The total amount of masonry executed up to the end of this year was as follows: Granite delivered, about 570,000 cubic feet, of which some 560,000 were set, whilst upwards of 120,000 cubic yards of rubble masonry and concrete had been built.

At Queensferry (See Fig. 41) the erection of the steel work during 1887 was vigorously prosecuted, and by the end of the year the columns had been carried up to their full height, the diagonal tubes between them (See Fig. 47) completed, and the top members between them erected. In short, the superstructure over the piers, which, including the internal viaduct, forms the central portion of the cantilever, was practically erected. The southern bottom members had been carried out to nearly the end of bay 1, and the first bay of bracing between them erected. (For method of erection of bottom members, see subsequent account; also Figs. 38, 39, 40, 44, 54, &c.) The first ties and struts were also well advanced, and the erection of wind bracing of the latter had been commenced, whilst the first vertical ties, with their bracing, and the support to the internal viaduct, had been erected.

At the north end of Queensferry main pier the bottom members were slightly further advanced, whilst the first ties and first struts had been built to their junction with each other, and the first vertical ties had been similarly erected. In all nearly 5,000 tons of work were riveted up at this pier by the close of 1887.

At Inch Garvie (See Fig. 42) the vertical columns had reached full height by the close of the year, and the erection of the junctions at the tops were well advanced, whilst good progress had been made with the top members between the vertical columns. Nearly the whole of the bracing between the vertical columns was erected and riveted, and the horizontal bracing for staying the columns at mid-height was completed. The internal viaduct over the piers was finished. The southern bottom members had been carried out some 150ft., and a commencement made with the wind bracing between them. Ties 1 and struts 1 were well advanced. Similar progress on the northern side had been made with the bottom members and ties 1 and struts 1. In all some 6,000 tons of riveted work had been executed at this point by the close of the year under consideration. (For progress, see Figs. 45 and 49.)

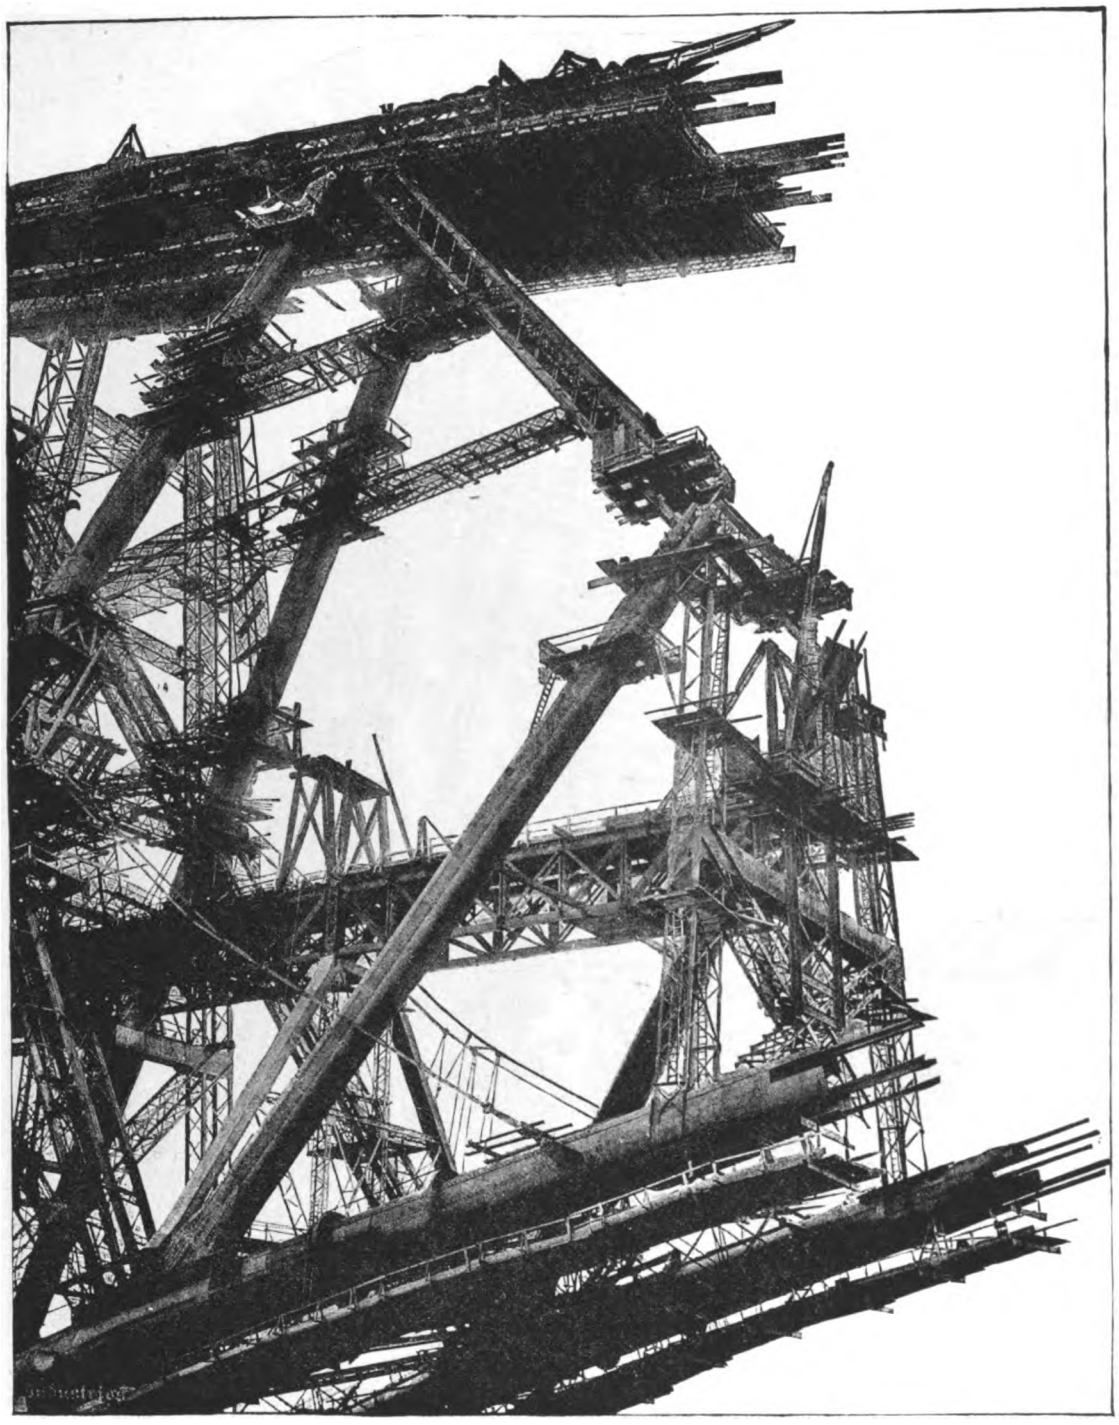

FIG. 61.—CANTILEVER FACING THE FIFE SHORE, 1888. SEE PAGE 30.

Passing on to the Fife side, the vertical columns had here also reached full height, and the top members between them had been erected; also the internal viaduct. The southern bottom members had been carried out some 170ft., and nearly two bays of wind bracing between them erected. The ties 1 and struts 1 had been well advanced, and the vertical ties 1, with their bracing, were complete. On the northern portion the bottom members were nearly as far advanced as those to the south, whilst the ties 1 and struts 1 were well in hand, and similar progress to that on the southern portion had been made with the first vertical ties and internal viaduct. In all upwards of 6,000 tons of material at this pier had been riveted up before the close of the year.

Progress in the shops and on the drill roads had been steadily maintained at all points during this year, and the whole of the bottom junctions for bays 1 were completed and ready for erection; the bottom junctions for bays 2 were all in hand, whilst all those for the top of bay 1 had advanced towards completion. The drilling of all the top members for bays 2, and the bottom members for bays 4, was completed, that for struts No. 3 and ties No. 5 being well advanced, whilst a commencement had been made with drilling the top member of bay 4 Some 48,000 tons of steel were delivered by the end of the year.

The number of men employed during the year averaged about 3,500. (For general progress during 1887, see Figs. 43 and the double-page supplement).

ERECTION OF THE BOTTOM MEMBERS.

Figs. 40 and 44 illustrate the method of building the tubular overhanging bottom member of the cantilever. This was 12ft. in diameter at the starting point, being reduced by $\frac{1}{8}$in. to the foot, and was sufficiently rigid to carry itself for a length of 120ft., supporting besides its own weight (which amounts to about 30cwt. per foot run) a steel cage or envelope, with the necessary crane and riveting machine. The envelope was rectangular, measuring 19ft. square, and was divided into six duplicate parts or panels, which were interchangeable. It was supported upon the tube by two circular rings, which were attached to the finished portion, and carried a 2-ton hydraulic crane of special design, on a travelling frame running upon the tops of its sides. As the tube was being built at the front end, the riveting was done between the two supporting rings, at the after part of the cage, by a machine similar to those employed on the columns of the steel pier. On the completion of a length of 16ft. (being that of one course), the supporting rings were moved forward, and two segments of the cage, which were each 8ft. wide, were passed from the after to the forward end, by means of the hydraulic crane; the riveting machine was then drawn up the tube 16ft., and the operations went on as before. The length of the first bay of the cantilever was about 180ft., and as the weight of this caused a greater bending moment than could be safely carried by the tube, it was supported by a temporary tie, formed partly of the links from the old Hammersmith bridge, and partly of plates taken from bay 3 of the top member, this being fastened to the columns about 150ft. up from the centre of the bottom member. (See Figs. 53, &c.)

The hydraulic crane referred to above had a simple form of construction, and possessed three independent movements, viz:—(1) Lifting and lowering the load; (2) describing a complete circle; (3) traversing the full length of the cage. As in the case of the lifting platforms for the erection of the vertical columns, the objects kept in view in the design of this apparatus were large working platforms for the men, together with cranes for dealing with the material, actuated by hydraulic power, and having a short lift. The several vertical movements which took place in the bottom members may here be noted: (1) a gradual fall, owing to increased weight as the tubes were gradually built out, and the leverage of the weight of the temporary plant increased; (2) a rise due to the pull occasioned by the weight of the link ties; (3) a rise caused by the increased pull on the link ties when the platforms and main plate ties were placed in position; (4) a rise as the hydraulic rams raised the member; (5) a gradual fall on account of the stretching of the main plate ties as the weight of a portion of the first bays of the cantilever and plant was transmitted to the ties; (6) a rise due to a temporary pull put in force before connecting the permanent ties; (7) a gradual fall as the cantilevers were built out, thus leaving the bottom members with only the normal initial stress when the bridge was completed.

ERECTION OF LOWER PORTION OF BAY 1.

The erection of the lower portion of bay 1—*i.e.*, the lower portion of struts 1, the first vertical tie and support to the internal viaduct—was by means of a lifting platform similar, but smaller, to those already described, and raised in a like manner by hydraulic jacks placed in the vertical ties and on the vertical columns. (See Figs. 46, 49, and 51.) Before describing this platform, it may be here explained that it was originally intended to have carried it up to the top members, and indeed to have built them on it, but the project was abandoned, as it was found that the men could work without such platforms being used.

"The experience gained," says Mr. Cooper, in addressing the Iron and Steel Institute in 1888, "up to this time, as to the ability of the men to work unaffected in situations more exposed than was at first deemed advisable, as well as the ease with which large and heavy pieces of material could be raised great heights by ordinary cranes and tackle, with little interruption from anything but a strong wind, rendered it possible for a great modification to be made in the mode and apparatus made use of, and these platforms were carried no higher than the level of the intersection of the first ties and struts. The appliances used on the erection up to this point, though amply fulfilling all the conditions of the problem, were necessarily slow in action, and costly to make, put together, and take down; and it must be borne in mind that when the vertical columns, with their bracing, and top and bottom members connecting them, were completed, an immensely powerful support was available, from which the other members of the cantilever and the internal viaduct could be held up by temporary stays as securely as if supported by staging on the solid ground below."

Digitized by Google

The Riveting.

The riveting of the bottom members, vertical columns, and diagonal struts between them, was performed by specially designed hydraulic riveters. (See Figs. 29 and 30.) The apparatus consisted of two heavy steel girders, 22ft. apart, with angle distance pieces as framing, which, when covered with netting, made a complete cage, from which nothing could fall. Independent rams were employed for the holder-up and snap, and were capable of being raised or lowered on slides by a small hydraulic jack. The action of the riveter is thus summed up by Mr. Cooper: "The rivet, properly heated, was placed from the inside into the hole, the holder-up was brought opposite to it, the valve admitting the water was turned on, the holder-on thrust the rivet in up to the head, and held it there whilst the ram on the outer girder closed the rivet, the same valve admitting water to both rams; but a slight check in the branch leading to the outer ram permitted the rivet to be sent home by the inner ram before the pressure was applied to form the snap." About 800 rivets could be closed by this apparatus in ten hours. The cylinders, both inside and outside, were capable of putting a pressure of 40 tons on the point of the rivet on any part in a length of 17ft. The inside girder did not travel bodily like its fellow outside, but rotated, as shown in the illustration, upon trunnions at its ends. The ordinary portable hydraulic riveter used on the works is shown in Fig. 31, whilst the method of riveting up the junctions by hand is illustrated in Fig. 63, and by this machine again in Fig. 64.

Rivet Furnaces.

Figs. 32–35 illustrate the small reverberatory furnace employed for heating the rivets, often required at the rate of three or four per minute, in confined spaces. The heat was derived from the combination of blast-furnace residual oil delivered through a special disintegrator, in a fine spray, by air at about 20lb. per square inch pressure. The furnace itself was a small fireclay-lined iron box, rounded at the end admitting the oil. A galvanised iron tank, holding 15 gallons, supplied fuel sufficient for about 4½ hours. The following is a further description of this furnace: "In the centre of the domed top of this tank there is fixed a cross-piece, having one 1in. and three ½in. branches. The inch branch is made fast to the top of the tank, and has passed down through it a ½in. pipe, which reaches to within an inch of the bottom. Air at 20lb. per square inch is conveyed through the flexible hose H to one of the two horizontal arms of the cross-pieces, its admission being controlled by a small brass plug cock. The air pressing on the surface of the oil forces it up the central pipe already mentioned, from whence it is carried by the flexible hose H_1 to the branch B on the side of the burner. The second horizontal branch of the cross-piece is connected by the flexible hose H_2, through which the air passes to the end D of the burner. The burner, as can be seen from the sectional elevation, is something like an injector; the central pointed nozzle through which the air passes is moved longitudinally by means of a butterfly nut A, regulating by its motion the quantity of oil passed into the furnace, which, as already stated, is forced by the air through the branch B into the annular space round the nozzle. The quantity of air passing through the burner is controlled by the cock C. To light the furnace when it is all connected as described, the air is turned on at the cock H, which controls the supply, and the oil is forced into the burner through the branch B. The nozzle is then drawn back by the butterfly nut the necessary amount, and the air passing up its centre disintegrates the oil into a fine spray, when it can be ignited by a match or lighted piece of waste. The air which passes through the nozzle is not nearly sufficient for combustion, the remainder being drawn along the upper heated passage in the furnace already described, and, coming down through the holes in the arched roof, meets the spray just as it enters. The furnace is less costly than a coal one large enough to do the same work, and it has the additional advantage of being about one-sixth of the weight. The regulation of the heat is complete; rivets are heated uniformly, and the apparatus is under perfect control, and in every respect a complete success. A small furnace, 1½ft. square and 4ft. long, will," Mr. Cooper states, "heat 2,000 rivets per day at a cost of about four shillings."

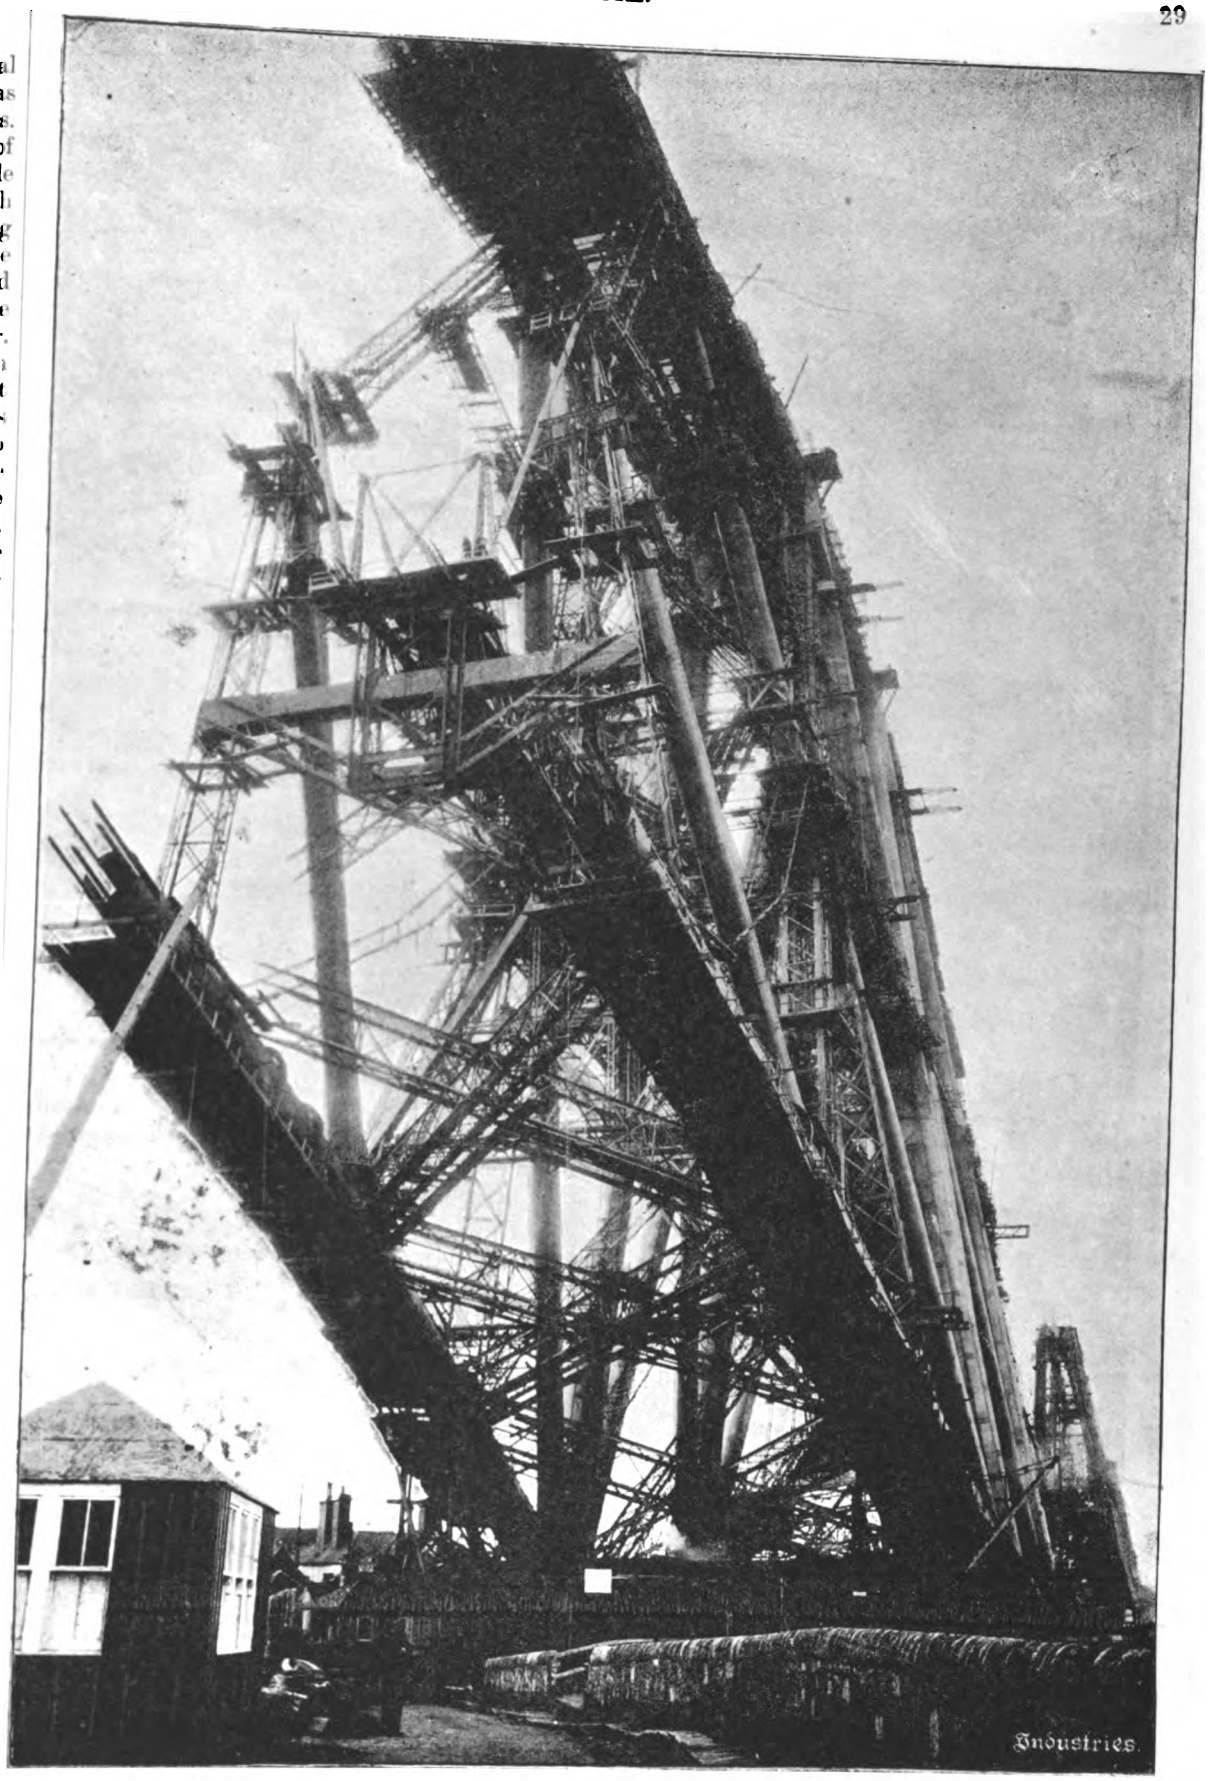

Fig. 62. North Side of Fife Main Pier, 1888. See Page 30.

PROGRESS DURING 1888.

As in the previous year, the temporary plant added during 1888 had reference almost solely to purposes of erection, and comprised the remainder of the double derrick cranes, with detached winches, for the erection of the internal viaducts, and subsequently of those portions of the bottom members and other parts within reach; a large quantity of staging for riveting and erecting purposes; an addition to the timber jetty at South Queensferry, and numerous hand derrick cranes of the ordinary type; winch to hydraulic riveters; and further hoisting gear and cages. The masonry work executed during this year is comprised within brief limits. The south cantilever pier was carried up some fifty additional feet, and the arches of the south abutment completed. On the Fife shore similar progress had been effected with the building of the north cantilever pier. The total quantity of granite delivered up to the end of 1888 was about 615,000 cubic feet, of which about 610,000 cubic feet had been built in position, whilst over 113,000 cubic yards of rubble masonry and concrete work had been placed in the piers and abutments.

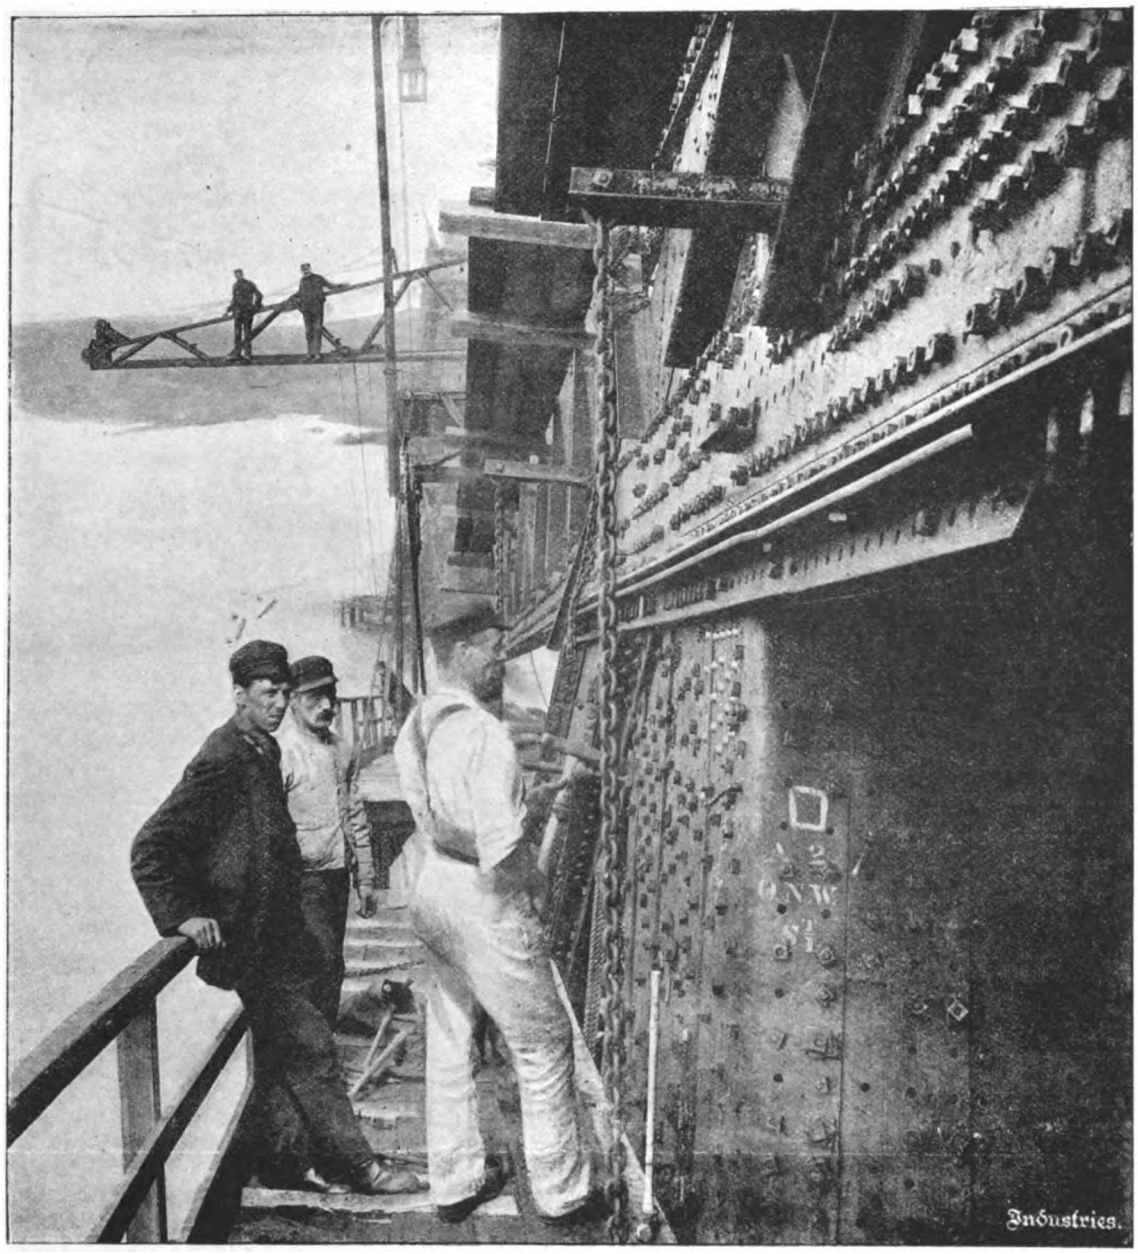

FIG. 63. RIVETING THE TOP OF STRUT 1 OF NORTH QUEENSFERRY PIER. SEE PAGE 29.

Progress with the erection of the steel work during 1888 made rapid strides. (See general views, Figs. 59 and 65.) Commencing at Queensferry, and with the southern cantilever, the junctions of ties 1 and struts 1 were duly made (See Fig. 52), and these members carried out to their junctions with the lower and upper members respectively (See Fig. 53); the second bay was practically completed, and the third bay well advanced towards being finished; the top members had been carried out some 420ft. from the vertical columns, and more than half this distance had been riveted up (See Fig. 65); the main girders and bracing of the internal viaduct had been extended over 400ft. from the vertical columns (See Fig. 48). On the northern cantilever progress was even more marked. By the end of the year under consideration the principal members of the third bay were erected, the junctions at the ends of the bottom members in place, and those at the ends of the top members well advanced. The fourth struts were also commenced. Over 300ft. of the bottom members were riveted and some 260ft. of the upper ones similarly completed. Upwards of 11,000 tons of material had been riveted up at South Queensferry by the close of 1888.

Turning now to progress at Inch Garvie, and commencing with the southern cantilever, practically the whole of the first and second bays were completed at this date, and the bottom members of bay 3 had been built out to a distance of more than 400ft. from the vertical columns; the top members were built out for a distance of 400ft. from the vertical columns, of which about half was riveted up, whilst the girders and bracing of the internal viaduct had been extended to about 400ft. from the vertical columns.

On the north cantilever progress had been made as follows: Bays 1 and 2 were practically completed, and the second about half riveted up; the bottom members of the third bay had been built out about 350ft. from the vertical columns, of which some two-thirds had been riveted up; the top members had been built for a distance exceeding 300ft., also about two-thirds riveted up; whilst the girders and bracing of the internal viaduct had been carried out some 360ft. from the vertical columns. In all about 13,000 tons of riveted work had been executed at Inch Garvie by the close of 1888. (See Figs. 54 and 65.)

At North Queensferry south cantilever bays 1 and 2 had been completed, and the latter about two-thirds riveted, and the bottom members for bay 3 carried out to the end of the bay, whilst a commencement had been made and good progress attained with the ties and struts of this bay. The bottom members were built for 450ft. from the vertical columns, which all had been riveted up with the exception of some 50ft. The top members had similarly reached a distance of about 450ft., more than half of which had been riveted up. The whole of the vertical ties and the trestle at the centre of bay 3 were in position, and the girders and bracing of the internal viaduct had been erected to the end of that bay, or 425ft. from the vertical columns.

In the second bay of the north cantilever similar progress had been made to that in the southern one. The bottom members had reached about 450ft. from the vertical columns, of which about three-fourths had been riveted. Struts 3 were well in hand, and the top members carried out some 400ft., of which more than half had been riveted. The girders and bracing of the internal viaduct had been carried some 450ft. from the vertical columns. A total quantity of 11,000 tons of steel work had been riveted up at North Queensferry by the end of this year. (See Figs. 51, 55, 56, 61, and 62.)

In the workshops excellent progress was maintained throughout this year, and by its close progress stood as follows: Bays 1 and 2 drilled and fitted; bays 3, the whole of steel drilled, and fitting practically completed; bays 4, all the main members, the internal viaduct, and cross girders for internal viaduct drilled, fitting of top and bottom junctions well advanced; bays 5, all the main members drilled; bays 6, the top members drilled, and the main ties put in hand. About 54,000 tons of steel were delivered up to the end of 1888, and the average number of men employed at the close of the year was about 3,000.

ERECTION OF TOP MEMBERS AND UPPER PORTIONS OF STRUTS AND TIES.

The upper members and the upper portions of the struts and ties were erected by specially designed cranes, resting on the upper members, and following up the work as the cantilever advanced. Figs. 57, 58, and 60 (See also Fig. 66) illustrate the plant under consideration. The horizontal jib of the steam crane which projected towards the end of the cantilever was 35ft. long, and was capable of being slued 115 degrees on each side of the centre line of the bridge. The material was lifted by a steam winch, the main drum of which was constructed to coil about 400ft. of $1\frac{3}{4}$in. wire rope. The whole arrangement was mounted on a sliding steel framework, to which a large platform for the men was suspended. At the back a second crane, actuated by hydraulic power, was placed, along the horizontal jib of which ran the supports for the hydraulic riveter. Underneath the top member, and rigidly attached to the crane carriage, four longitudinal girders carried a platform 76ft. long by 45ft. wide, of such length as to extend from the extremity of the steam crane to that of the hydraulic one. When a length had been finished in front of the crane, the whole arrangement, as already stated, was slid forward on the part just completed, and another length was commenced. When, in the case of bay 1, the overhang was 125ft., and the stress on the vertical bracing (temporarily doubled) had nearly reached the working stress of $6\frac{1}{2}$ tons per square inch, with the end of the members deflected about 8in., a temporary continuation of the vertical tie in the centre of the bay was built up to the underside of the top members, and, jacks being interposed, the latter were raised the amount they had deflected, and secured by wedges. Similar extensions of the vertical ties in the other bays were subsequently made, in order to temporarily support and adjust the top members above them. These cranes were similarly employed in building down and in building up the ties and struts respectively, small timber stages (See Figs. 52 and 53) being built around these members for the men, and raised or lowered by ordinary tackle to follow the erection. To prevent undue strain on unsupported lengths of both struts and ties, temporary struts from the vertical columns, light girders and wire ropes, were extensively employed, as shown in the various diagrams and illustrations of the erection of the cantilevers.

ERECTION OF THE INTERNAL VIADUCT.

The internal viaduct (See Fig. 72), which was composed of lattice girders with spans from 39ft. to 145ft., and a buckle plate floor with trough girders, was erected by cranes with two masts and jibs of the derrick type, the former in line transversely with the axis of the bridge and 16ft. apart, strongly braced together, and secured to a movable timber frame, advancing along the outer rail troughs.

Digitized by Google

"Each jib," writes Mr. Cooper, "is raised and lowered by means of a wire rope passing round a drum on the mast, but the wire rope lifting the material is passed through a sheave at the extremity of the jib; thence it is led over a sheave down the centre of the mast, and, by means of guide-pulleys, to some convenient point on the finished structure, whence to a steam winch. The object of separating the power from the crane is to lessen the weight concentrated at that point, the viaduct there being extended much in advance, and as a rule acting as a cantilever, its outer end being temporarily supported by wire ropes to some part of the finished structure. When the viaduct girders are being extended by these cranes little staging is required, the men being able to do the bolting up standing in the trough forming the top and bottom booms."

PROGRESS DURING 1889.

We now pass to the year in which the bridge was joined and the gigantic undertaking successfully finished. But little temporary work falls to be recorded during the year, beyond the addition of sundry hydraulic riveters, hand derricks, and minor plant.

The completion of the south abutment was accomplished this year, and nothing remained to finish the north and south cantilever piers, carried up to a height of 213ft. O.D., save the dressed granite cappings at the top, which were delivered, and only awaited the final arrangements of the ballast boxes at the cantilever ends to be built into position. (See Fig. 73.) The total quantities of masonry work executed are given elsewhere. The erection of the steel work executed during 1889 naturally divides itself into two sections—the completion of the cantilevers and the erection of the central girders—and is accordingly so treated.

The Completion of the Cantilevers.

The interest of the work executed in 1889 mainly centres in the erection and joining up of the 350ft. spans connecting the cantilever ends, and subsequently described. The erection of the remaining portions of the cantilevers had been carried out and completed in a manner similar to that already fully dwelt on, and by appliances and methods described in detail. Up to the close of May in this year 14,000 tons had been riveted up at South Queensferry, over 16,000 at Inch Garvie, and upwards of 14,000 tons at North Queensferry. By November 7th the entire structure was erected and joined up. By the end of the year the riveting completed, and the permanent way rapidly pushed on, whilst painting, both internal and external, was under execution. The joints of the tubes were made tight with tar concrete, with which the skewbacks had also been filled.

Referring to the illustrations which we are enabled to place before our readers for the year 1889, Fig. 67 shows the South Queensferry pier, looking westward from Long Craig pier. H.M.S. "Devastation," on the right hand, gives a scale to the bridge, whilst the nearness of completion of the undertaking is evidenced by the rapid approach of the southern cantilever towards the south cantilever end pier. The different cranes on the top members stand out sharply against the sky line, and explain themselves. Fig. 69 shows a view taken from the internal viaduct on Inch Garvie, between the two northern vertical columns, looking northwards. The rail troughs are clearly illustrated, whilst struts 1, 2, and 3 on either side will be observed. The corresponding ties are also clearly brought out, whilst the cross bracing of struts No. 2 stands markedly out in the foreground of our illustration. The top members at the upper portion of the picture will also be noted; and the various temporary stages and platforms for erection lend additional interest to the subject. In the background the southern Fife cantilever appears as a confused mass of steel work. Fig. 68 gives a view taken from the riveting stage on Garvie southern cantilever, then resting on bay 3. The upper members of bays 1 and 2, and the platforms and gangways for the erectors, are clearly shown.

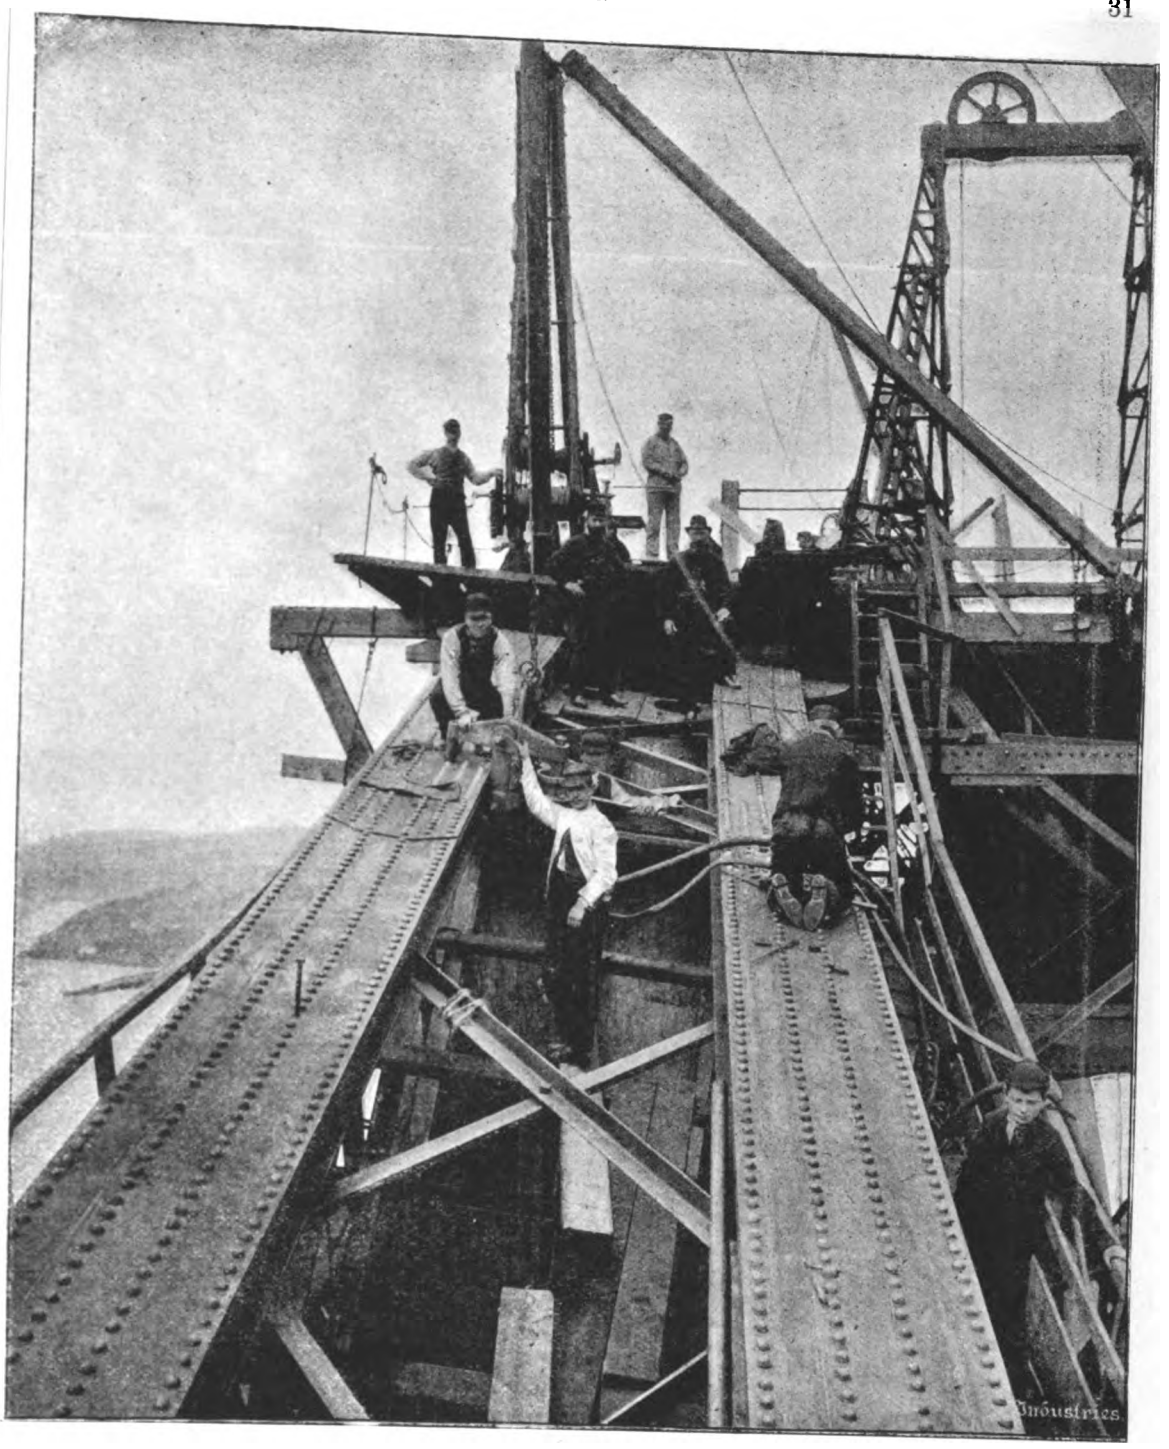

Fig. 64.—Riveting the Top Members of the Cantilevers. See Page 29.

Fig. 71 portrays a curious effect produced by looking towards Inch Garvie from between the main northern circular piers of Queensferry whilst standing on the timber jetty. The wind bracing between the bottom members of Queensferry northern cantilever is clearly shown in the upper portion of the picture; and a similar view is obtained of that between the Inch Garvie bottom members of the southern cantilever. The old castle on Inch Garvie stands out to the left of the illustration, surmounted by the different wind gauges, by means of which a careful record of the force of wind visiting the Forth is duly recorded. The northern or Fife shore is seen in the background. Fig. 70 was taken from the south cantilever end pier, when standing at rail level, and looking northwards at the Queensferry southern cantilever. On either side of the picture, the vertical columns connecting the bottom members with the junctions of ties 5 and struts 5 are clearly marked. Behind them struts 5 are seen; the bottom members in bay 5 are shown in cross section, and the cross-girder connecting them is prominently indicated. Below, the wind bracing between the bottom members appears in a confused mass; whilst above, an even more intricate and hopelessly entangled forest of bracings, struts, and ties appear, forming an almost solid mass, interwoven and interlaced beyond all possible recognition. The method employed in erection is well shown by this view, the various timber platforms on the different members, supported variously by chains and steel ropes, indicating with remarkable clearness the *modus operandi* adopted in erection. A curious piece of perspective may be noticed in connection with the bottom members, which at the bottom are 120ft. apart from centre to centre, whilst at the middle of bay 5, where the ends of the tubes appear in the illustration, the dimension from centre to centre, which looks nearly double the width of the members at the bottom, is only 40ft. Such is the curious effect produced in perspective by the narrower end being some 600ft. nearer the spectator than the wider lower portion of the bottom members. Fig. 80 represents the cantilever end pillars on the drill roads—that portrayed being the one for Queensferry north cantilever—the non-expansive end of the 350ft. central girder. This span is free to move at its northern end at the pillar at the end of bay 6, Garvie south cantilever. The brackets for the pin joints on the upper and lower crossed girders may be seen in the illustration.

Fig. 85 was taken from Inch Garvie looking in a south-westerly direction. The first bay of the central girder of the south main span is shown in place,

and the top member crane is shown resting on the main temporary tie which then connected these portions of the structure. Fig. 81 is a general view of the bridge from the east, as it appeared on the 17th September, 1889. The Queensferry cantilever is shown on the left, the Inch Garvie cantilever in the middle, and a few bays of the North Queensferry cantilever on the right. At the time the picture was taken the south central girder was complete, and only about 25ft. of the northern remained to be built.

In Figs. 82, 83, and 84 we give outline sketches to show the progress of the structure at different periods, the dark lines representing the parts erected at the several periods.

Fig. 86 is an end view of the central girder when about half built, taken from the extremity of the opposite side advancing to meet it.

When the southern or fixed arm of the Queensferry cantilever had been built out sufficiently to enter the recess in the masonry pier at that point, it became possible to ascertain exactly the longitudinal and transverse alteration of position in the former due to changes of temperature, and a simple apparatus was made use of to register these, so long as the end of the cantilever was free to move. To the lower plate of the last bottom member a board about 18in. square was fixed. Upon this was secured a sheet of drawing paper. Attached to the masonry was a bracket of timber, through which a pencil, with its point resting on the paper, was passed, free to move vertically, but rigidly fixed otherwise. As the cantilever end, affected by temperature, moved about, the pencil marked on the paper the character and extent of this movement. A few of the diagrams thus drawn have been reproduced in full size, and are shown in Figs. 74, 75, 76, 77, 78, and 79. They are specially interesting as being drawn by a giant arm 670ft. in length, and weighing about 5,000 tons. The maximum movements observed were recorded on the 21st and 22nd June, 1889, when that transversely was 5·2in., and longitudinally 1·1in., the shade temperature ranging at the time from 53° to 71° F.

THE CENTRAL GIRDERS.

Mr. Baker foreshadowed in his paper on the Forth Bridge, read at the Southampton meeting of the British Association in 1882 (before any contract had been entered into, or the final studies completed), the method which has been adopted in the erection of the central girders. He then said: "The central girders will also probably be erected on the overhanging system, temporary connection being formed between the ends of the cantilevers and the central girders. The closing lengths or key-pieces, at the centre of each 1,700 feet span, will be put in on a cloudy day, when there is little variation in temperature; and the details will be so arranged that the key-piece can be completed and the temporary connections cut away in a few hours, so as to avoid any temporary inconvenience from expansion and contraction." Notwithstanding this plain statement of opinion, many engineers, and most of the general public, have rigidly held to the idea that the central girders would be built on the shore, floated out on pontoons to the site, and then gradually raised into position by hydraulic appliances.

The putting in place of large girders, where the great height above the water level generally debars the use of scaffolding, has almost universally in Britain been accomplished by the method above mentioned, that is to say, building on shore, floating out, and raising by hydraulic power. The main spans of the Britannia, Saltash, and Tay Bridges are familiar instances of this, and it would naturally occur to many people that the method so successful in these ought to have been adopted in the present case. But circumstances alter cases, and it became obvious to those who carefully thought out the matter that the cantilever system offered special advantages for the building of the central girders in their final position, so that practically the launching and raising method of erection received little if any consideration. It was justly maintained that when the arms of the cantilevers, weighing about 5,300 tons each, and projecting out from the piers 680ft., had been successfully built in place, it would be found but child's play, so to speak, to continue them as a temporary part of the central girders 175ft. further with an extra weight of about 400 tons.

The composite girders are each composed of two side girders with cross-girders attached to their bottom booms, which cross-girders carry the troughs in which the rails are placed; buckled plates form the flooring of footpaths at the sides and of the spaces between the troughs. Each side girder is hog-backed (See Figs. 87 and 89), and in cross section (See Fig. 88) is inclined inwards, just like the outer faces of the cantilevers. The length of each is 350ft., the depth at the centre is 51ft. 5in., and at the ends 40ft. 2in. The top and bottom members are open troughs, formed of side plates 3ft. deep, and bottom and top plates respectively 3ft. wide, of varying thickness. The bracing is formed of plates, struts, and ties, stiffened as required, dividing the girder into eight bays, each 43ft. 4in. in length. From the intersection of each strut and tie a vertical tie supports the bottom member, and plate cross-girders, 4ft. deep at the centre, are attached to the bottom members, at the foot of each main tie and vertical tie. The alteration in form of the cantilevers due to the effects of temperature, wind, and rolling load necessitated

very careful consideration of the method of the attachment of the ends of the central girders to the cantilevers supporting them, in order that under the varying conditions no part should be subject to the destructive action of racking or excessive strain thus arising. Each of the three main cantilevers is, as regards movements longitudinally and transversely, rigidly attached by one skewback to one of the four masonry piers forming its base. At Queensferry and Garvie the north-east skewback, and at Fife the south-east, is thus fixed. It therefore necessarily follows that at some point in each portion of the superstructure between these points allowance must be made for the variation in its length produced by change of temperature. The portion between Garvie and Queensferry is 1,970ft., and that between Garvie and Fife 1,710ft. in length, and the maximum provision as regards length is 24in. in each portion, and is located at each end of the Inch Garvie cantilever. The connection here between one end of each side of the central girder and the end of the cantilever is made through a long rocking post, with ball and socket joint ends (See Figs. 88 and 89), which transmits the weight from the upper portion of the end post of the former to the lower part of the end post of the latter. At a mean temperature, taken as 51° F., the rocking post will stand vertical, and as the superstructure lengthens or contracts through change of temperature the posts will rock backwards or forwards, permitting the centre girder to advance towards or retire from the cantilever at that point. A massive tongue X (See Fig. 91) projects horizontally from the last cross-girder of the cantilever, and passes through the first cross-girder of the central girder. In this tongue is a slotted-hole Y with faced sides, along which travels a block Z, 15in. square, secured by a bolt V, 9in. in diameter, to the first cross-girder of the central girder. A similar arrangement, though of a lighter character, is provided between the top bracings of the end posts of the cantilever and the central girder. These together completely control the movement due to change of temperature, compelling it to be longitudinal alone, without lateral or vertical divergence. The effects of temperature, which cause most important changes by enlarging the structure in a longitudinal direction, also necessitate careful consideration as regards warping action. During summer, when the sun shines with great power on one side of the cantilever, and when on the opposite side at the same time a cold wind may be blowing, the outer end of the cantilever will be deflected away from the sun some inches, a similar effect being produced by wind blowing at right angles to the bridge. If this be the case with any two cantilevers supporting a central girder, it is obvious that the axis of the central girder will not be in the same straight line with the axes of the cantilevers in their deflected position; consequently the central girder will appear to revolve in a horizontal plane about the bolt connecting the block with the first cross-girder of the central girder. The ends of the rocking posts, being formed with ball and socket connections, permit this revolving movement, but had suspending links, which are more usually made use of for making such a connection, been adopted here, they would by this movement be subject to an undesirable torsional strain. Therefore the rocking posts, a rare but not altogether novel idea, have been made use of in preference to suspending links, partly for this reason, and partly because the bearing area of a ball having a 12in. radius in a socket 22in. in horizontal diameter is so much greater than could be obtained in a link and pin of reasonable dimensions. At the other ends of the central girders, where they are supported respectively on the ends of the Queensferry and Fife cantilevers, the connection is made by upper and lower bed-plates, with a large steel pin 8in. diameter interposed between them, as shown in Fig. 90. The horizontal revolving movement of the central girders is simply that provided for by the sliding of the lower bed-plates on steel base plates. It is controlled by an arrangement of bolt and block similar to that at the other end of the girder already described, but the faced side of the tongue projecting from the cross-girder of the cantilever does not admit of any longitudinal movement.

The first operation connected with the building of the central girders was to attach a stage to the undersides of the end of the cantilevers, sufficiently

Digitized by Google

large and strong to permit of the building thereon of the end post and adjacent half of the first bay of the central girder. On account of the end post of the central girder being enclosed on three sides within that of the cantilever, it was necessary to put this part together and rivet it in a position in advance of its ultimate site, and when this was done to thrust it back until it rested either on the long rocking posts or upon the bed-plates, according to which end of the central girder was being operated upon. As soon as these first half-bays had been thus placed and adjusted in their ultimate positions, their top members were attached to the top members of the cantilevers by heavy ties (See Fig. 89), one on each side of each girder, there being four in all at each end of each central span. These ties were composed of three flat plates, 50ft. long, 26in. wide, and ⅞in. thick. The attachments at either end were made partly by rivets and partly by turned bolts, sufficiently numerous to make them of ample strength. The calculated stress on each of these ties at the maximum was about 280 tons. Similarly the continuity of the compressive stresses between the lower members of the cantilever and of the central girders, whilst the latter were prolongations of the former, was secured by two steel wedges interposed between faced steel frames attached to the ends of these bottom members. These wedges were 3ft. long, 8in. wide, and tapered from 5in. to 1¼in. in thickness. The thrust upon them at a maximum, including the effect of winds, was about 500 tons.

These temporary connections having been made, and the crane used in building the top members of the cantilever having been pushed along over the temporary ties, and adjusted to its altered level by steel-covered wooden wedges, the operations of building the central girders were then briskly proceeded with. For each bay these were generally as follow: The cross-girder at the centre of the bay was hoisted and held in correct position by special derricks, supported on the outer rail troughs. Next, the inner side plates of the bottom members were connected to those already built, and the ends of the cross-girders secured to them. The outer side plates were then added, and the struts and ties were built up and down respectively to their intersection. The vertical tie from that point to the bottom member was put in place, the struts were then extended for their whole length, and the top member, plate by plate, extended to them. The cross-girder at the end of the bay was next hoisted into position, and the bottom members completed past it, and secured to it. The ties were then built down and connected—thus completing a bay. The time occupied in building one such bay, 40ft. in length, in some cases did not exceed 36 working hours. A slight variation was made in some cases by building out the top member first, and using that as a point of attachment for the tackle by which the cross-girders were placed in position, which, as a rule, was the last thing done in each half-bay. From what has already been remarked with reference to the effect of temperature upon the superstructure between the fixed points, it will be obvious that making the joint between the two halves of each central girder, and converting them from temporary prolongations of the cantilevers into independent girders, was by no means a simple matter, but one to which the Engineers and Mr. W. Arrol had devoted much consideration, inasmuch as the physical connection had to be arranged in such a way that it could speedily be made of ample strength, and also that during the operations no part of the permanent structure should be subject to excessive strain. The method adopted was as follows: To each end of the flange plates of the bottom members of the two half girders, temporary covers, G H (See Fig. 93), 1in. thick, were attached by bolts. Sandwiched between these on the outside of the vertical webs D were inserted the steel plates F, 8in. wide, 1⅞in. thick, and on the inside between the vertical webs were placed, as shown, three plates, of about the same thickness. At the Garvie end these thick plates were formed with slotted holes, 1⅞in. wide and 4in. long. After the bottom members were in place, with their ends so arranged as to be 4in. apart at a temperature of 60° Fahr., observations, extending over three days or so, were made to ascertain what effect the temperature during that time produced in opening and closing the gap, and, as soon as sufficient information had been obtained, the small holes in the covers of the Queensferry or Fife ends of the centre girders were templated at, as near as possible, the probable maximum temperature at the time when the joint was arranged to be made. The thick plates were then drilled from these templates, and bolted up between the covers of the Queensferry or Fife ends.

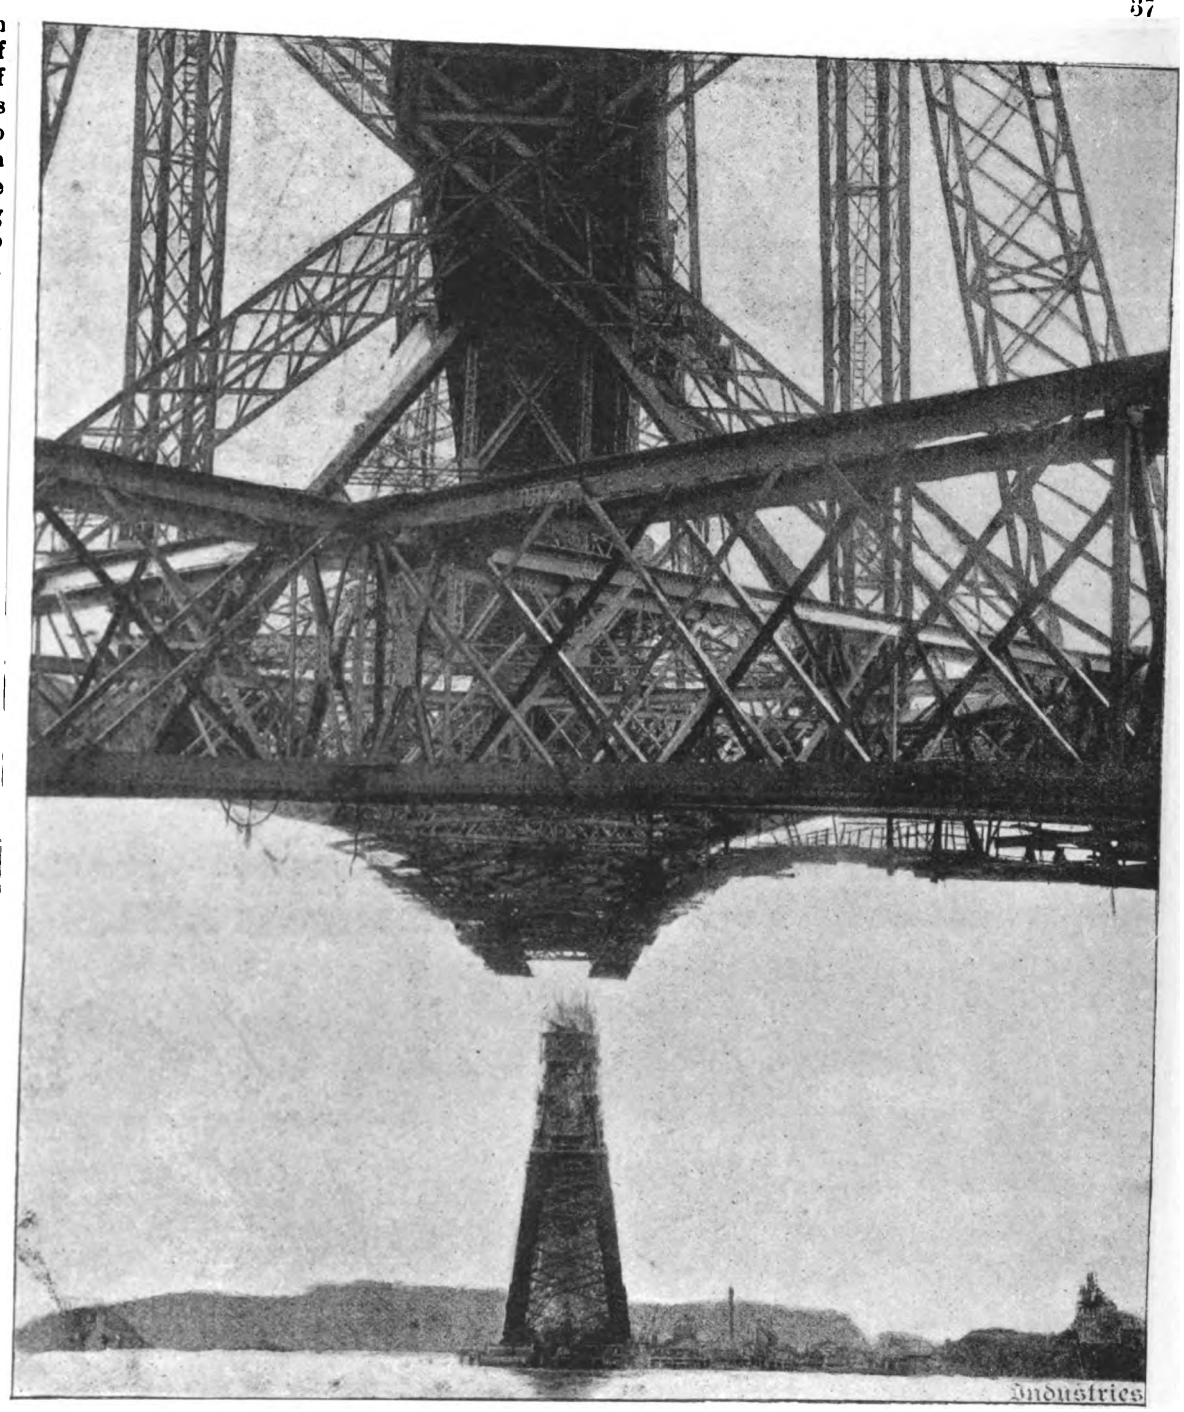

FIG. 71.—VIEW LOOKING NORTHWARD FROM UNDERNEATH QUEENSFERRY CANTILEVER, 1889. SEE PAGE 31.

When this was completed, and the maximum temperature attained, hydraulic power was applied to assist in closing the gap to the desired extent, and the 1⅞in. bolts were rapidly inserted into the holes prepared for them, and tightly screwed up. This operation completed the temporary connection of the two halves of the bottom members of the central girder sufficiently to deal with the tensile stresses (about 480 tons) arising at that point when their transformation into an independent girder took place.

As this connection was made at the maximum temperature of the day, contraction of the superstructure between the fixed points before mentioned made itself felt, and the result was that the central girder was raised to a slight extent, sufficiently to relieve much of the pressure on the wedges between the bottom members of the cantilever and central girder, and enabled them to be withdrawn. Before doing this, however, it was requisite to make good the 4in. gap between the ends of the top members at the centre of the central girders, which was accomplished as follows:—The ends of the vertical webs of each top member were reinforced by the addition, on each side, of a plate ⅝in. in thickness, D D (See Fig. 92). Outside these again, on each side, were covers F F, ½in. thick, extending across the joint, and riveted to the webs on the Garvie side, but not connected to the webs on the other side. Three vertical angle bars, 4in. by 4in. by ½in., on a ½in. plate, on each side, stiffened the ends of the webs, and temporary horizontal plates G H (See Fig. 92) were used to stiffen the top flange plates and the lower edges of the vertical webs. When it had been ascertained that the minimum temperature had been reached, and that the wedges at the bottom members could be removed, large cottars or wedges, 3ft. 6in. long, 2in. wide, tapering 1 in in. 36, and of sufficient thickness to fill the gap, were inserted between the reinforced ends of the webs of the top members. The removal of the wedges at the bottom members, together with the faced plates against which they rested, and the expected rise in temperature, threw the top members of the central girders into compression, and the bottom members into tension, and the operation as a temporary measure was completed. The next proceeding was to put on, and rivet up, permanent covers to the sides of the vertical webs of the bottom members, and to the flanges of the top member, securing, at the same time, the loose ends of the

Digitized by Google

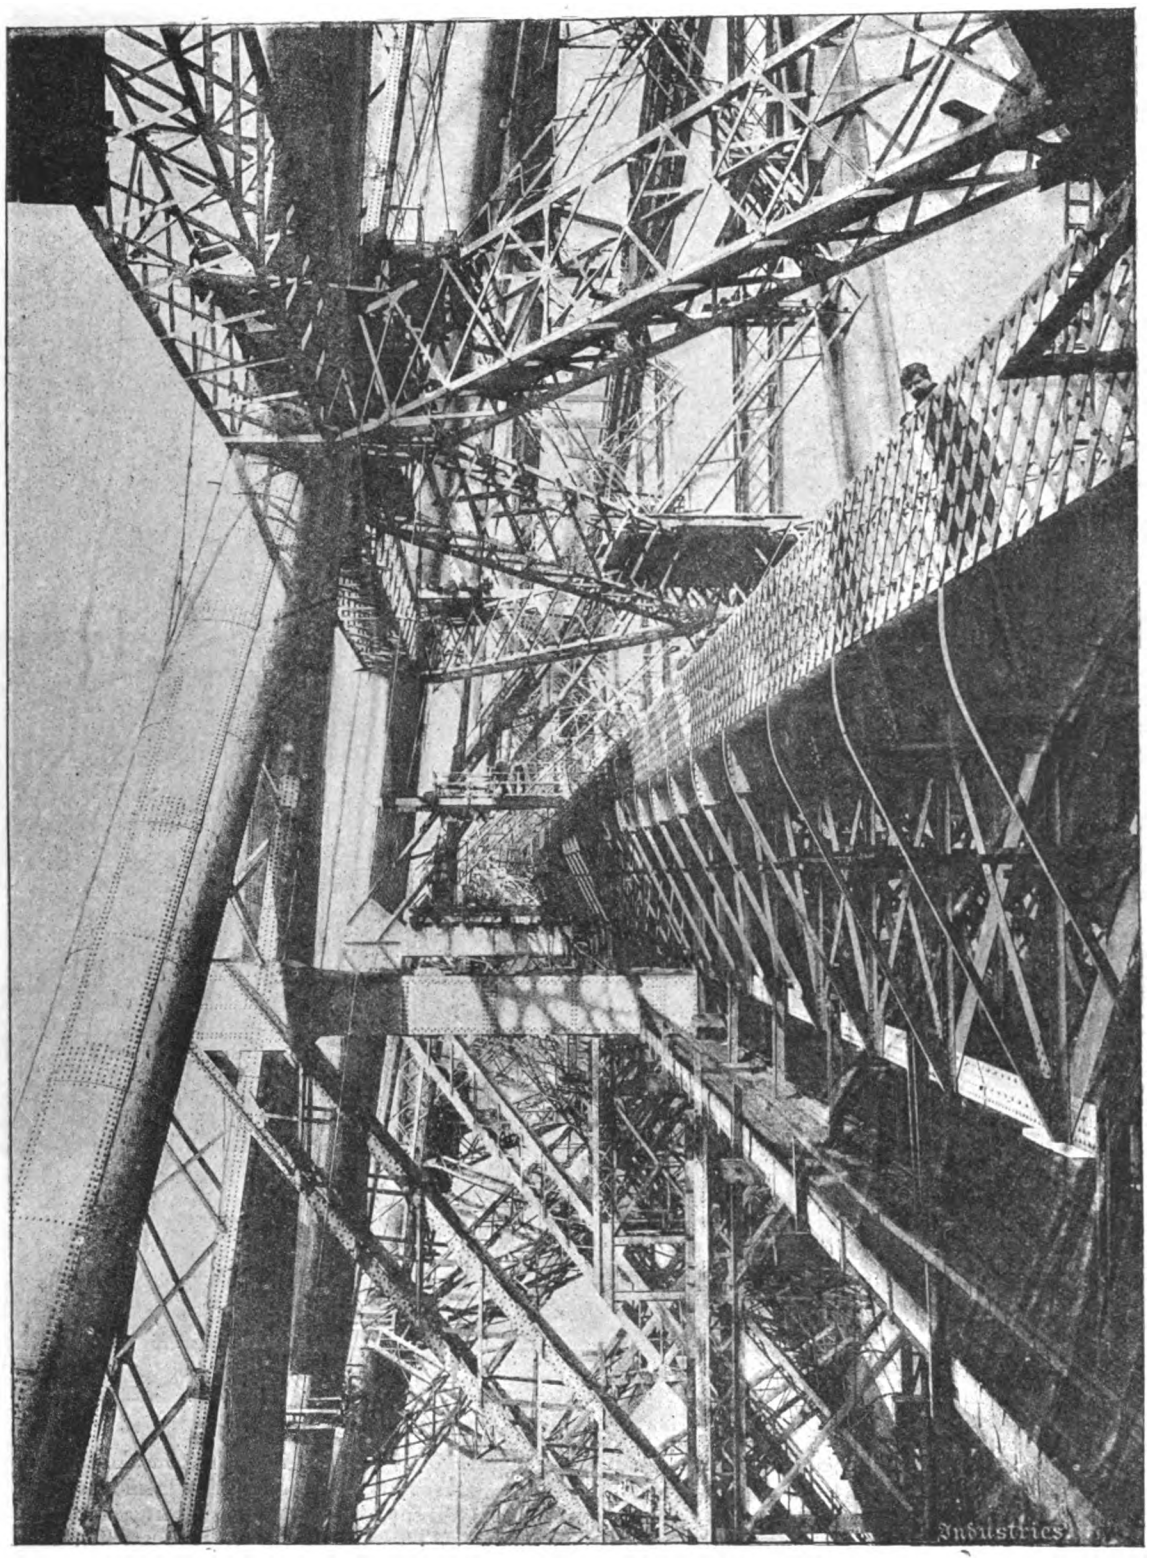

FIG. 72.—OUTSIDE VIEW OF INTERNAL VIADUCT. SEE PAGE 30.

covers to the vertical webs. When this was accomplished the temporary plates were removed from the flanges of the bottom members and the permanent covers fixed and riveted, thus finally completing the permanent connection. In view of the ends of the two half girders, at the commencement of the operation, not coming exactly opposite each other, they were adjusted horizontally by pulling one from the other, and vertically by loading the cantilevers to the necessary extent.

THE PLANT USED IN BUILDING THE BRIDGE.

HYDRAULIC BENDING AND SETTING MACHINERY.—The bending and setting of the plates and angles for the tubes and their connections were a prominent part of the labours of the workshops, and formed, along with the other plant, the subject of a valuable paper read by Mr. William Arrol, in Edinburgh, on August 2nd, 1887, before the Institution of Mechanical Engineers. Figs. 94 and 95 illustrate the largest of these presses, which was capable of exerting a pressure of 1,600 tons between the dies.

The cylinders were 24in. diameter, and rested on two longitudinal girders bedded on concrete. The fixed overhead table, to which was attached the upper block, was connected with each cylinder by two iron columns. The lower table was fastened to the rams, and rose and fell with them. Blocks of different curvatures were employed to suit the varying diameters of the tubes. The two gas-heating furnaces were placed at the end of the press, and were connected with it by an iron table with rollers, so that the heated plates were drawn direct by means of hydraulic power into the bending press. A final squeeze to each plate after cooling adjusted any curvature that might have taken place during that process.

Numerous smaller presses were employed, consisting mainly of a simple ram fixed to the upper of two girders, which were bound together at the ends, the lower girder supporting the block on which the material to be operated upon rested.

PLANING MACHINERY.—The edges of the plates were planed by specially designed machinery. Some idea of the amount of planing that had to be executed may be formed when it is stated that no sheared edges were permitted in the structure, the "distress" occasioned to the metal being in every case removed by planing, whilst, as a certain percentage of the stress in compression had to be taken up by the butting of the plates, instead of wholly by rivets, as in the tension joints, such planing had to be performed with the best possible workmanship. Figs. 96 and 97 illustrate the machine for dealing with the side edges of the curved plates, which was practically an ordinary planing machine, with some modifications. It was provided with special double side cheeks, between which were fixed two swivelling tool boxes, one on each side of the machine. The curved blocks (shown in the figures) were securely fixed to the sliding table, and carried the plate to be dealt with. Both the tools acted at the same time, and cut both on the backward and forward travel of the table.

The planing of the ends of the curved plates was performed by a specially designed tool. (See Figs. 101 and 102.) In this machine the plate was firmly secured to a fixed table, and the tool, attached to a swinging pendulum, was driven backwards and forwards by a connecting rod. The length of the pendulum was adjustable to suit the varying diameter of the tubes. The tool, which was fed by hand, cut on both strokes. At the other end of the connecting rod an ordinary planing machine, similar to that subsequently described, was arranged for planing the edges of flat plates.

Figs. 98, 99, and 100 show the usual pattern of planing machine for dealing with the edges of rectangular plates. In this machine an addition was made, viz., a second cutter working at right angles to the first one, thus enabling two side edges to be simultaneously treated. In this machine, therefore, all four edges could be planed in two settings, with the certainty of the edges being truly at right angles to each other. In other machines of a similar type two saddles were placed upon the main slide; in others, again, both tools were fixed to the same saddle. The tees, angles, and other sections were faced as a rule by cold steel saws, in order to secure good butting.

DRILLING MACHINERY.—"The principle kept in view," says Mr. Arrol, in his paper already referred to, "is that, wherever possible, girders, tubes, &c., should be drilled only while their various parts are temporarily built and held together by bolts in the position they will finally occupy in the finished structure; in this way the highest class of work is obtained."

Figs. 103 and 104 represent the drilling machines, each complete in itself, for drilling the tubes. Each machine, which was large enough to embrace the entire circumference of the tube, consisted of a wrought iron under-frame, which carried, besides the engine and boiler driving the drills (the former only shown in our illustrations), two large cast iron annular rings, or head-stocks, round which ten drilling slides travelled circumferentially. The slides moved around the rings, and, as each drill had also a longitudinal motion parallel to the tube, any hole in the work could be dealt with along a length of 8ft. The tube rested on timber blocks, and the machine travelled forward after completing each length of 8ft.

In the case of the lighter tubes, the rate of drilling was as high as 12 lineal feet of tube per shift of 10 hours; this represented about 800 holes drilled.

Figs. 105, 106, 108, and 109 illustrate the drills used for dealing with the booms of all girders, which moved along rails, running on each side of the work, fixed to blocks. These machines consisted of a double carriage with upright columns, connected by a cross-beam to other framings for shafts, pulleys, &c. Nine drills on slides, attached to the columns and cross-beam in front, and four drills on as many radiating arms at the back, were capable of boring either vertically or horizontally. The fixed drills, which were self-feeding, served for all holes of the regular pitch, whilst the movable ones, which were fed by hand, dealt with the odd holes. By this machine

thirteen holes could be drilled simultaneously in a single boom.

The single-arm radial drilling machine, shown in Fig. 107, operating one drill, was a very serviceable tool, and will be readily understood from our illustration. The machine made a complete revolution round the supporting column.

THE STEEL USED IN THE CONSTRUCTION.

Passing on to the steel, which forms so large an item in the undertaking, the tests may be briefly summarised. For material subject to tensile strains an ultimate tensile strength of from 30 to 33 tons per square inch of section was required from strips, cut either with or across the grain, with an elongation of at least 20 per cent. in a length of 8in.; for steel subject to compression a tensile strength of from 34 to 37 tons per square inch of section was required, either lengthways or crossways, with an elongation of at least 17 per cent. in a length of 8in. Bend tests were also taken from each slab or bar: these, either cold, or after being heated uniformly to a low cherry red and cooled in clear water at 82° Fahr., were required to stand bending double to a curve whose inner radius was equal to 1½ times the thickness of the plate or bar. The strips, either tempered or cold, were 1½in. wide, and cut either lengthways or crossways. A tensile test was taken from every 50 slabs or bars. The usual requirements as to freedom from lamination and injurious surface defects, &c., were specified.

The rivet bars had a tensile strength from 26 to 30 tons per square inch, with an elongation of at least 20 per cent. in 8in.; and, either cold or tempered, they had to stand bending to a curve whose inner radius was equal to 1½ times the thickness of the bar. All holes were drilled, no punching being permitted. Similarly every edge was planed, effectually removing the distress caused to the edges by shearing.

Particular attention was paid, in dealing with heated plates and bars, to put no "work" on them when at blue heat, the dangerous limit of temperature between about 600° and 400° Fahr. Annealing was carefully performed on all junction plates, bars, &c., which had been subjected to a large amount of work; and due precautions were taken, when such annealing could not be done simultaneously on the whole plate or bar, that no abrupt termination of the line of heat was permitted. The bending, planing, drilling, &c., are dealt with in describing the special appliances for these operations under the head of "Workshops and Plant."

About 54,000 tons of Siemens-Martin steel were used in the entire structure. The principal makers were the Steel Company of Scotland (Blochairn and Hallside Works), where the labours of the metallurgists, Mr. James Riley, seconded by Mr. F. W. Dick, succeeded in producing a material eminently adapted in all respects to fulfil the requirements of the engineers. The following firms also supplied lesser quantities:—The Landore Company, Messrs. Colville & Sons, Dalzell Steel Works, Motherwell; the Mossend Steel Works, the Clydesdale Steel Works, the Parkhead Forge, Messrs. Coats of Coatbridge (now Messrs. Goodwins, Jardine, & Co., Ld.), and the Clydebridge Steel Company.

The rivets were made by the Clyde Rivet Company from bars manufactured by the Steel Company of Scotland or by the Dalzell Steel Works.

A small quantity of iron was used in the caissons. Cast iron was employed only in the form of weights to fill the boxes at the free ends of the cantilevers. A small quantity of cast steel formed the bearings, &c., of the ends of the central girders on the cantilever ends.

THE WIND PRESSURE ON THE BRIDGE.

A series of valuable and interesting experiments on the subject of wind pressure have been carried on at the bridge since its commencement by the Engineers, who held that the high pressures occasionally recorded were due possibly to the small area of pressure-board operated on by the wind, and that such high blasts were of very local area. To test these points by direct observations they caused three wind gauges, or pressure-boards, to be erected on the top of the old castle on Inch Garvie, the first presenting an area of no less than 300 square feet to the wind, and facing east and west. The second has a circular disc only 1½ square foot area, and is fixed similarly to the first. The third gauge has the same area (1½ square feet), and is free to swivel square to the wind in any direction.

As the results of a series of experiments Mr. Baker, writing in 1884, says: "I think it is pretty well established, by our two years' experiments, that the effective pressure per square foot on a large and comparatively heavy board averages only about two-thirds of that indicated by an ordinary light anemometer."

Two heavy gales occurred on December 12th, 1883, and January 26th, 1884, the latter being of exceptional violence, as evidenced by widespread havoc throughout the country. The small fixed gauge on Inch Garvie on this occasion registered as high as 65lb. per square foot; and, but for the fact that the pointer was unable to move further, might have indicated a greater pressure. Mr. Baker, distrusting the anemometer, experimented with it, and found that the sudden application of a pressure not exceeding 20lb. caused 65lb. to be registered. The recording apparatus of the wind gauges was accordingly altered. On March 30th, 1886, during a westerly gale, the pressures recorded by the large, small fixed, and revolving gauges were 19lb., 31lb., and 26lb. respectively. In December of the same year the large gauge recorded 9lb., and in January and February, 1887, the highest readings in each month were 10lb. and 15lb. respectively, while in the autumn of the same year 10½lb. per square foot was the maximum reading.

In November, 1888, a gale of exceptional severity swept over the northern portion of the British isles. The first three days were stormy and unsettled on the Firth of Forth, and a gale from the south-west set in, accompanied by heavy showers of rain. The violence of the gale may be judged from the fact that the North British Railway Company's ferry boat plying between Port Edgar and North Queensferry was unable to make a mid-day trip, owing to the high sea running.

The wind gauges at the Forth Bridge, placed on the old castle on Inch Garvie, registered high pressures. The large gauge, which presents an area of 300 square feet, and is fixed parallel to the centre line of the bridge, registered a maximum pressure of 27lb. per square foot. The small fixed gauge parallel to the same line, and presenting an area of 1½ square feet, registered 41lb. per square foot, a pressure equivalent to a speed of wind of about 90 miles per hour. The revolving gauge on Inch Garvie, which is described above, indicated a pressure of 35lb. per square foot. The severity of the gale was abundantly shown by the damage done on land and on sea. The Firth of Forth was the scene of several shipping disasters,

and the appearance of Leith Harbour, where vessels had put in to repair after the storm, bore ample testimony to the severity of the weather they had experienced.

Under such circumstances, it is satisfactory to note that, beyond some slight damage to the temporary timber stagings of the Forth Bridge, some unimportant injury to the sheds, and the displacement of loose planking, no harm was done to the permanent erection, or to any temporary steel structure of any description. Work was, of course, suspended during the gale; and, considering the many casualties reported from elsewhere, it is pleasing to state that, beyond a minor accident to one of the men, who was slightly injured by a plank being blown against him, no accident of any kind happened during one of the severest and most prolonged gales experienced in Scotland for many years. The huge structure in all respects realised the anticipations of its designers.

"A pressure of 56lb. per square foot has been allowed for in designing the bridge, this pressure striking the whole or any part of the bridge at any angle with the horizon and acting square or obliquely upon an area equivalent to twice the plane surface of the front girders, with a deduction of 50 per cent. in the case of tubes. The total wind pressure so derived amounts to 2,000 tons on the 1,700ft. span and 7,900 tons on the whole superstructure of the bridge included between the two cantilever end piers." The strength of the structure to withstand wind force is abundantly demonstrated by Mr. Baker's remarks before the British Association in 1882. He then said:—"The Forth Bridge as designed will be relatively stronger than any other bridge yet constructed. Owing to the large deadweight and the spread of the girders at the piers, a wind pressure equivalent to 2cwt. per square foot upon the surface of one girder would be required to overturn the bridge, assuming it not to be held down by bolts. The holding-down bolts provided, however, about double the resistance to overturning. So 4cwt. of wind pressure per square foot upon the single surface would be required to upset the bridge; and under this ideal pressure, though the wind bracing would, it is true, be on the point of failing, none of the great tubes or tension members of the main girders would even be permanently deformed."

It will thus be seen that, with a wind pressure eight times in excess of that allowed in calculation, the bridge would still stand, with a further margin of strength.

During the great gale in November, 1888, the large fixed gauge registered 27lb., or almost exactly half the 56lb. required by the Board of Trade to be provided for, and if the small fixed gauge, presenting 1½ square feet only, registered 41lb. per square foot at the same time, and a reduction to 27lb. per square foot was found with an area augmented to 300 square feet, a still greater diminution may be hoped for in actual pressure per square foot on the bridge when the area operated upon has a maximum length of 1 mile by a maximum height of 361ft. The force of the wind during the storm known as the Tay Bridge gale, from the unhappy accident caused, was stated by experts to be 30lb. per square foot.

THE APPROACH RAILWAYS.

In dealing with the approach railways, we propose to sketch in brief outline those immediately connected with the Forth Bridge itself and owned by that company. (See Map, Fig. 122.)

The North Queensferry and Inverkeithing Railway was commenced in September, 1887, and this line, about two miles in length, has presented many fea-

tures of exceptional difficulty, owing to the extremely irregular and rocky nature of the country traversed. After leaving the north end of the Forth Bridge the line is carried on an embankment for a short distance; then, traversing a tunnel, another embankment is reached; after which a rock cutting and embankment terminate in the tunnel under Inverkeithing. The second embankment caused much difficulty and delay, being over the site of what is pronounced by geological experts to be an extinct volcano, and into which over 100,000 tons of material had to be thrown before the bank would stand.

The bridges present no features of special interest, the principal one being a steel viaduct of four spans, which carries the line across the main road from North Queensferry to Inverkeithing. (See Fig. 110.) The cost of this line is about £90,000, the total amount of excavation being estimated at about 300,000 cubic yards.

The contract was secured by Messrs. William Arrol, & Co., contractors for the Forth Bridge, and was, with the South Approach Railway, next described, the special care, amongst his other duties, of Mr. Thomas Scott.

The South Approach Railway, some three-quarters of a mile in length, was also constructed by Messrs. Tancred, Arrol. & Co., for the Forth Bridge Railway Company, and runs from the southern abutment of the Forth Bridge to Dalmeny. The line, the total cost of which is about £10,000, presents no characteristic calling for detailed remarks; the northern portion consists of an embankment, that to the south cuts through clay and rock. The former was dealt with by means of one of Dunbar & Ruston's 10 h.p. steam navvies, made by Messrs. Ruston, Proctor, & Co., engineers, Lincoln, working in the boulder clay, and filling two hundred waggons in the day of twelve hours, viz., about 600 cubic yards. Had the material under excavation been less difficult to deal with, a considerably larger quantity would have been tipped. (See Fig. 112; also *Industries*, Vol. V., pages 252 and 256.)

A station is in progress at the north end of this line, on the road near Rosshill, which in a short time will be the scene of much marshalling of trains and interchange of traffic travelling by the Forth Bridge route.

The Winchburgh and Dalmeny Line, 4½ miles in length, forms a direct and important communication between Dalmeny and the main line between Edinburgh and Glasgow, and places Glasgow in direct communication with the Forth Bridge. Work was commenced in August, 1889, and is being pressed forward rapidly, with a view to completion in March.

The contract was secured by Mr. William Arrol, and the estimated cost is placed at about £45,000. Upwards of 200,000 cubic yards of excavation are required, whilst seven larger bridges, and a number of lesser ones, together with heavy culverts, have to be built. The line traverses a pleasant agricultural district, well wooded, through properties belonging

to the Earl of Hopetoun, the Earl of Rosebery, and Mr. Russell.

The Corstorphine and Dalmeny Line forms the direct communication between the Forth Bridge and Edinburgh, running from Dalmeny to Corstorphine on the main line between Edinburgh and Glasgow. This line, which is five miles in length, is being carried out by Mr. William Arrol, and presents no features of exceptional interest. The heaviest cutting occurs near the Dalmeny end, under Craigiehill, and is about half a mile in length, and requires the excavation of some 300,000 cubic yards of boulder clay. Three steam navvies have been in active operation continually at this point since the inception of the undertaking. The largest bridge is that crossing the River Almond, to the east of Boathouse Bridge, and consists of three spans, the central one 140ft., and those of each side 45ft. The line, which presents no special engineering difficulty, traverses a quiet rural part of the country, somewhat intersected by roads, as evidenced by the necessity of constructing no fewer than twenty-eight bridges between Dalmeny and Corstorphine.

The total quantity of excavation is estimated at half a million cubic yards, and the cost of the entire undertaking (exclusive of land acquired) at some £60,000. The railway station at Corstorphine, in anticipation of the large increase of traffic, has been entirely rebuilt and remodelled, on a considerably larger scale, by Messrs. S. Young & Sons, of Edinburgh.

Operations on the Inverkeithing and Burntisland Line, which is seven miles in length, were commenced in 1887. The line leaves the present Inverkeithing and Dumfermline route a little to the north of the former burgh, and, after traversing an undulating farming district, strikes the shore and skirts the Firth of Forth until Burntisland is reached. A colliery railway, running down to the small harbour of St. David's, is crossed, and heavy works, including the lowering of this line for some three-quarters of a mile, were necessitated. The line passes through the woods between Aberdour and Burntisland, skirting the shore; and the beauty of the surroundings will doubtless prove no small attraction to visitors. The embankments are protected by stone pitching from the waves of the Forth. Much rock was encountered in the cuttings, and the total amount of excavation in the line is estimated at about 600,000 cubic yards. Numerous bridges (in all about thirty) occur for various road crossings, &c., but call for no special remark. The cost of the undertaking is estimated at about £145,000. The engineers are Messrs. Galbraith & Church, and Messrs. Waddell & Sons, of Edinburgh, secured the contract.

A short line, known as the Cowdenbeath Line, some three miles in length, from Cowdenbeath to Kelty, saves a considerable loop in the present system. This work was executed by Messrs. Charles Brand & Co., of Glasgow, and presents no features of special interest.

A similar remark applies to the undertaking of widening the Inverkeithing and Dumfermline Railway, a work of some five miles in length. Originally constructed, so far as bridges, embankments, and cuttings are concerned, for a double line, though worked only as a single one, little else was requisite beyond the laying of permanent way for a second line, and the erection of new stations, to adapt it for main line traffic.

In the widening of the Kelty and Mawcarse Line, some ten miles in all, the bridges, being formerly built only for single line traffic, had to be taken down and rebuilt, care being taken, of course, not to interrupt in any way the usual service of trains. The stations have been similarly removed and reconstructed on a larger scale. The work presented no features of special engineering note, but the country traversed—the Loch Leven district, and the surroundings of the Lomond Hills—is rich in historic interest and pleasant pastoral scenery. The expense of the widening and reconstruction of the stations is placed at about £50,000. Mr. James Carswell was the engineer, and the contract was secured by Mr. John Best, of Leith.

The important branch known as the Glen Farg Line was commenced in 1888, and runs from Mawcarse to Perth. The first three miles, from Mawcarse to Damhead, necessitated the carrying out of ten cuttings and nine bridges. The valley of the River Farg is then reached, and numerous diversions of the river were necessitated by the narrowness of the glen. Two tunnels are constructed through a spur of the Ochil Hills, and further on an earthwork bank, of some 300,000 cubic yards, near Bridge of Earn, is required. The line throughout has been of a very heavy nature, upwards of a million cubic yards of excavation having been executed, of which some fifty per cent. was rock. The cost of this line, including that of the Cowdenbeath section referred to above, is estimated at about a quarter of a million. Messrs. Charles Brand & Sons, Glasgow, are the contractors.

SIR JOHN FOWLER.

Sir John Fowler, K.C.M.G., the engineer in chief of the Forth Bridge, is the eldest son of the late Mr. Fowler, of Wadsley Hall, Ecclesfield, Sheffield, and was born in 1817. His early training was under the late Mr. Towlerton Leather, the eminent hydraulic engineer, under whom he received practical instruction during the construction of the Sheffield Waterworks, and of railway work in Yorkshire. At the termination of his pupilage Mr. Fowler became assistant to the late Mr. Rastrick, who was then engaged, amongst other works, in the construction of the London and Brighton Railway. Mr. Fowler was subsequently appointed as resident engineer of the Stockton and Hartlepool Railway. He came prominently forward about this time as a witness before Parliamentary Committees, displaying those acute and sound qualities of mind which have at all times marked his distinguished career. At the age of twenty-seven he was appointed to construct the Manchester, Sheffield, and Lincolnshire Railway, and the numerous works connected with that undertaking, comprising a dock, floating pier, large hydraulic works, and a steam ferry, and he was subsequently engaged in designing and carrying out numerous railway enterprises, both at home and abroad. The Metropolitan Railway, in London, carried out by Sir John Fowler, would alone serve to stamp his name on the roll of famous engineers of the nineteenth century.

A mere enumeration of the many projects which have occupied his busy life would form a formidable list, suffice it to point out that, besides the Victoria and Pimlico line, in connection with which he built the first railway bridge spanning the Thames, and many railway projects both in England, Scotland, and Ireland, Sir John was for a time engaged in Egypt, and as consulting engineer to the Khedive and Egyptian Government rendered valuable professional services. Sir John Fowler is consulting engineer to numerous railways, amongst others the Great Western and Great Northern Companies. In 1885 he was created a Knight of the Order of St. Michael and St. George, in recognition of important services rendered during the Soudan Campaign, and he was President of the Institution of Civil Engineers in 1866.

MR. BENJAMIN BAKER.

Mr. Baker, partner with Sir John Fowler, and associated with him as engineer of the Forth Bridge, has seen varied and extensive practice, from the construction of the Metropolitan Railway in London to that of the Forth Bridge, and is at present engaged in carrying out the Chignecto Ship Railway in Canada, and the tunnel under the Hudson River at New York, in addition to numerous other undertakings, in different parts of the world. Mr. Baker is the author of several standard works on engineering, which are justly held in high estimation, and, as the writer of numerous authoritative papers on kindred topics, has appeared before most of the learned societies in this country. He possesses a large practice in arbitration cases, parliamentary evidence, and consultation work, his opinion being eagerly sought both at home and abroad, whilst on the American Continent the frequent requisition of his services abundantly testifies to the high esteem in which his engineering capacity is there held. Mr. Baker, who is still a young man, is a member of the Council of the Institution of Civil Engineers, an honorary

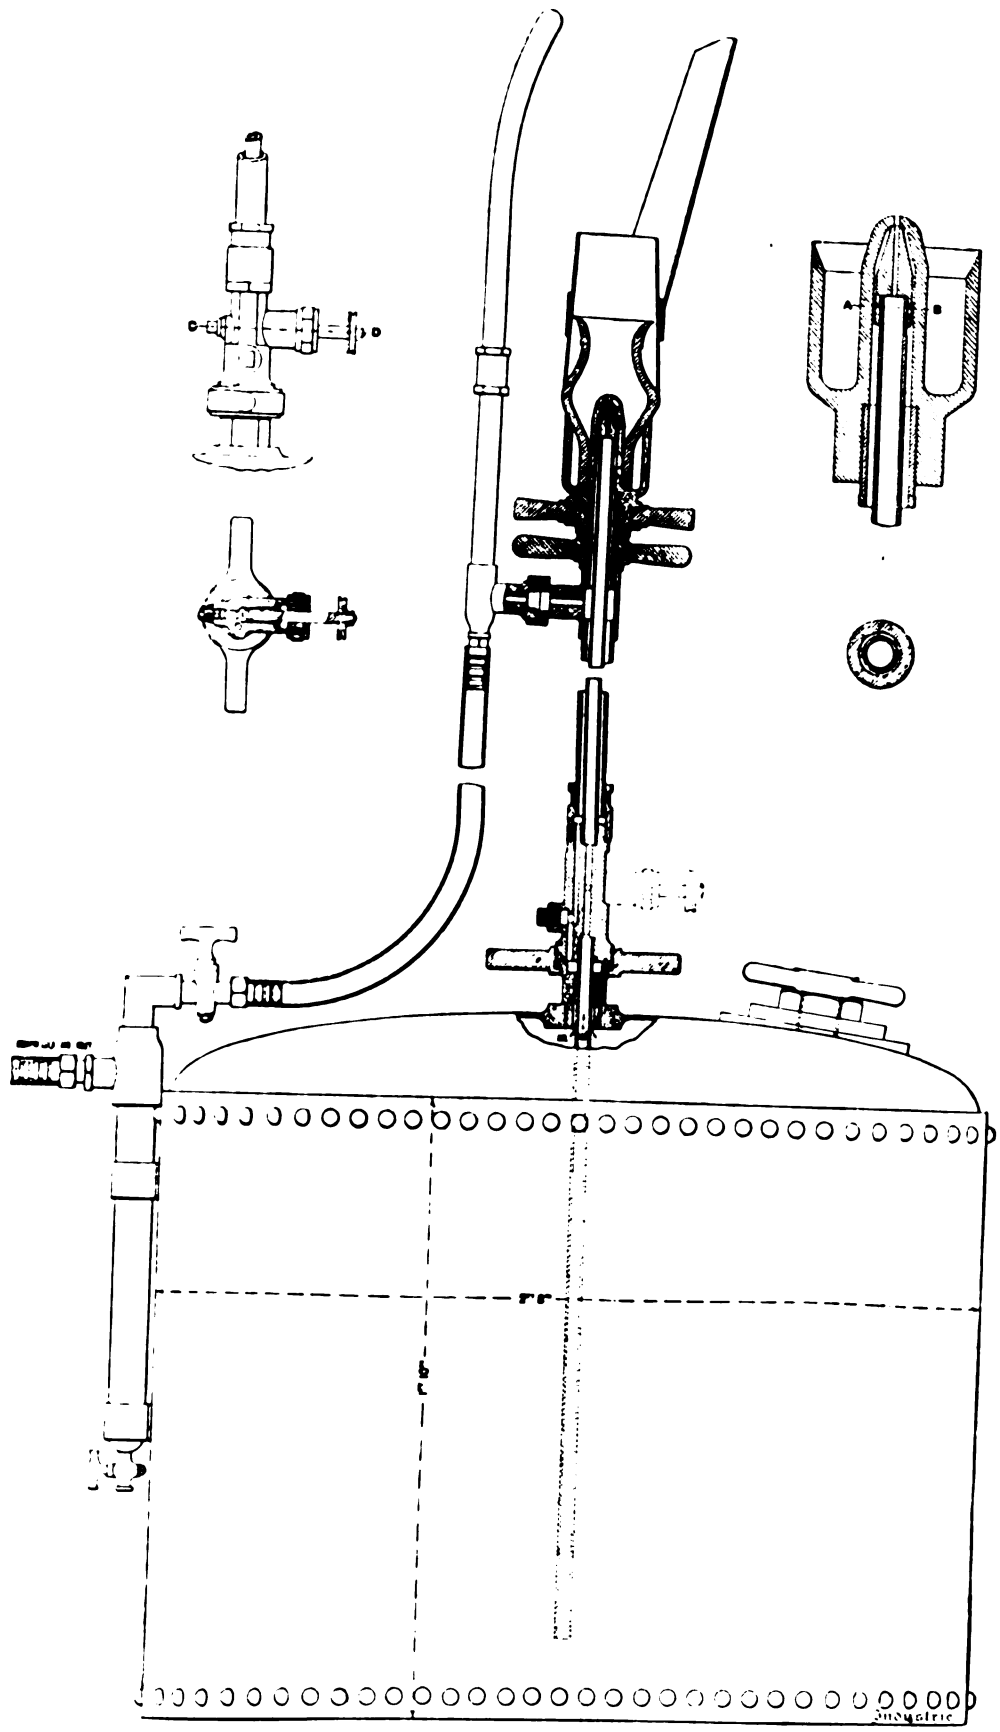
member of the Council of the American Society of Mechanical Engineers, a civil member of the Ordnance Committee, a Lieutenant-Colonel in the Volunteer Engineer Staff Corps, a Fellow of the Royal Society, and a Past President of the Mechanical Section of the British Association.

MR. WILLIAM ARROL.

Mr. William Arrol was born at Paisley, and at the early age of nine worked as a "piecer" in a cotton mill, being subsequently apprenticed as an engineer. Removing, after he had served his time, to Port Glasgow, he was employed as a mechanic by the firm of Messrs. Blackwood & Gordon, subsequently becoming a foreman in the boiler and bridge departments of Messrs. Laidlaw & Son's Works, Glasgow. In 1866 Mr. Arrol commenced business on his own account, with capital saved from his earnings. The workshops he laid out at Dalmarnock were conspicuous for the special machinery designed by himself for manipulating girder work. From this small beginning contracts of greater size were secured, and Mr. Arrol built the bridges on the Glasgow, Hamilton, and Bothwell Railway, the large viaduct across the Clyde at Glasgow on the Caledonian Railway, the South Esk viaduct at Montrose—in addition to various other bridges both for this country and abroad. Mr. Arrol then secured his first large contract—viz., that of building the new Tay Bridge, a work carried out from first to last with the utmost success. In 1882 Mr. Arrol, in conjunction with the firm of Messrs. Tancred & Falkiner, entered upon the Forth Bridge. The whole practical working of this gigantic undertaking has fallen upon Mr. Arrol, and forms a lasting monument to the indomitable energy and infinite resource of the contractor.

At the present time Mr. Arrol is engaged amongst other things in executing the steel superstructure of the Tower Bridge, London; also in carrying out the order for a number of bridges for the Manchester Ship Canal Company.



THE LIGHTING OF THE WORKS.

Among the earliest of the operations at the site of the Bridge Works was the arrangement of the electric light installations, which were somewhat extensive, as it was determined to provide sufficient artificial light to allow large numbers of men to be employed at night. There were many interesting features about those temporary installations, and there can be no doubt that they clearly demonstrated the ease and speed with which electric lighting on a considerable scale can be applied and adapted to large structures in course of erection. (See Fig. 113.)

The contracts for lighting the offices, machine shops, yards, and jetties on the south side of the river were entrusted to Messrs. Siemens Bros., and the smaller contracts on Inch Garvie and at North Queensferry to Messrs. Crompton & Co. During the sinking of the foundations electric lighting was extensively applied, and in several instances was of very special value. In the working chambers of the caissons, for example, where the men were working under trying conditions, the atmosphere being at a pressure of 32lb. per square inch, the aid of a powerful and reliable light was invaluable. Siemens differential arc lamps, with triple sets of carbons, were used for this purpose. The divers working on the exterior of the caissons were provided with incandescent lamps enclosed in strong protecting globes.

On the completion of the caisson work all the electric apparatus was re-arranged and much extended to provide for the erection of the superstructure. The installations, as remodelled and enlarged, may be described as follows:—At South Queensferry, where the engineering shops and yards for the preparation of the steel covered an area of 50 acres, there were three Siemens S.D.[6] dynamos, each supplying 120 amperes at 110 volts; one Crompton and one Siemens dynamo, each supplying 50 amperes at the same e.m.f.; and five Siemens S.D.[8] machines for series arc lighting, each with a current of 15 amperes at 300 volts. There was also a Crompton machine for the same purpose, wound for 15 amperes at 1,200 volts. Seven of these dynamos were driven by horizontal non-condensing coupled engines, indicating 120 h.p., by Messrs. Davey, Paxman, & Co., of Colchester, while separate incandescent lighting dynamos were driven by two smaller engines indicating respectively 30 and 10 h.p. On Inch Garvie, at the central cantilever, a pair of coupled "Caledonian" engines, by Messrs. Shanks, supplied

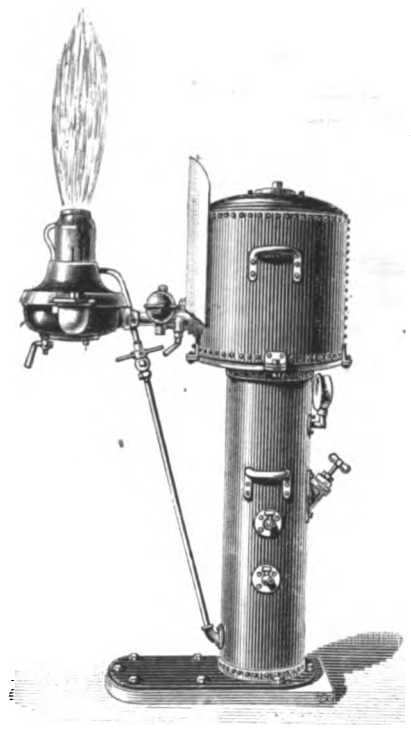

FIG. 121.—"LUCIGEN" LIGHT, PRESENT FORM.

power to four Crompton-Bürgin machines, two for arc and two for incandescent lamps. There was also a large Crompton dynamo for arc lighting, supplying 15 amperes at 1,200 volts. This machine was driven by Gwynne engines, coupled. At North Queensferry there was an installation almost exactly similar to that on Inch Garvie. The machine shops and sheds were lit by Siemens arc lamps, arranged in parallel circuits of two lamps in each, and distributed among the cantilevers were about 100 Crompton arc lamps. The "Sunbeam" incandescent lamps of the Sunbeam Company, of Gateshead, were also extensively used both on the erection and in the shops, and were found to be very economical and effective. It will be readily understood that the arrangement of the wires for such work presented many difficulties. The plan adopted was briefly as follows:—Overhead wires were run from the dynamo stations to distributing boxes at each of the piers, and flexible cables, tied to ropes, were led from these to the lofty stagings on the structure. Where such loose flexibles were impracticable, armoured cables were carried out along the girders. Groups of lamps in series with other groups were provided with automatic cut-outs and equivalent resistances to isolate the effects of accidents to the conductors. All arrangements were necessarily extremely portable, as the stagings were rapidly advanced with the progress of the work.

The "Lucigen," amongst other rival means of illumination, was tried at the bridge works, and proved itself the most formidable opponent of the electric arc. This light was described in *Industries*, Vol. IV., p. 599. The light is obtained by forcing creosote oil, or other heavy hydrocarbon, in the form of a spray, through a small nozzle, by means of air-pressure. The flame is about 3ft. 6in. long, and emits a light of great intensity and diffusive power. To maintain the air pressure for each light of 2,500 c.p. only ·25 h.p. is required. When first applied at the bridge, the oil, a bye-product in the manufacture of illuminating gas, was exceedingly cheap, and it seemed as if the new light would speedily extinguish its rivals. Such expectations were not realised: the price of the oil rose very considerably, and some disadvantages were experienced; but the makers have now brought out a portable "Lucigen," which gets over the trouble, and at a much reduced cost. We illustrate in Figs. 115–120 the old form of the "Lucigen" light, Figs. 115–119 giving details of the construction of the apparatus, and Fig. 120 a general view. Fig. 121 shows one of the latest forms.

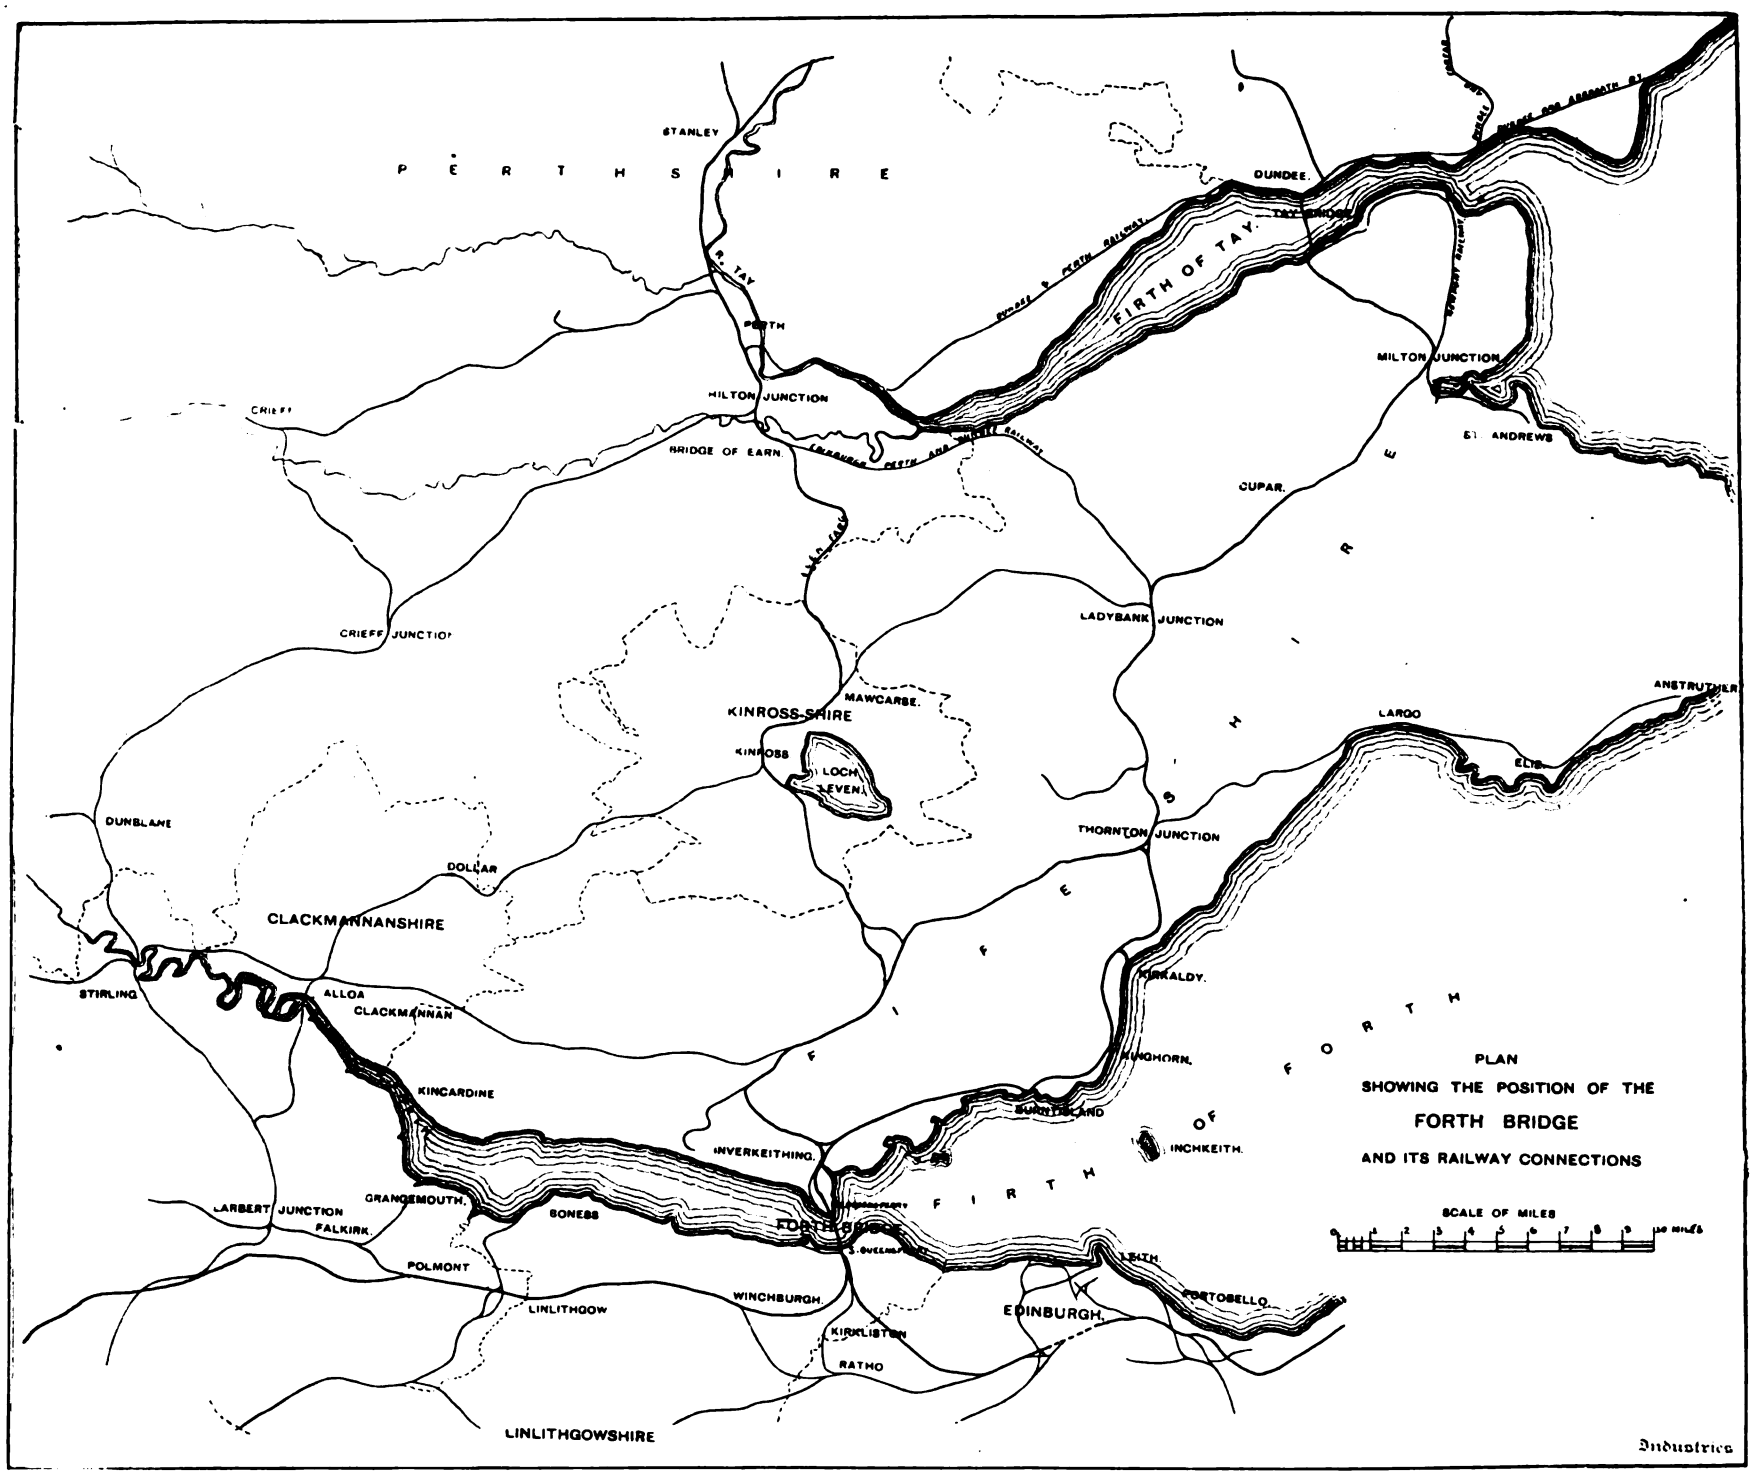

FIG. 122. MAP OF THE ENVIRONS OF THE FORTH BRIDGE. SEE PAGE 41.

The "Wells" light (Fig. 114) was also used in some parts of the Forth Bridge works, but, owing to this form of light only being placed in the market a year or two after the bridge was commenced, its use there was not so extensive as it might otherwise have been. Some "Wells" lamps were successfully used on the Inverkeithing Railway, on the Aberdour Railway, and also at South Queensferry.

Those who watched the erection of the bridge will long remember the striking aspect it presented on a dark night, when the outlines of the great cantilevers were thrown into bold relief by the long lines of brilliant lights.

CONCLUSION.

On Sunday, January 19th, 1890, the bridge received an undesigned testing from a severe gale, during which the wind gauges on Inch Garvie recorded a pressure of no less than 37lbs. per square foot. No damage of any kind resulted from this high wind, and the maximum lateral movement of the great cantilever was less than 1in. Two days later Sir John Fowler and Mr. Baker tested the two 1,700ft. main spans by placing on the centres two trains, each made up of fifty loaded coal waggons and three of the heaviest engines and tenders, the total load thus massed upon the spans had the enormous weight of 1,800 tons, or more than double that which the bridge will ever be called upon in practice to sustain. The observed deflections were in exact accordance with the calculations of the Engineers, and the bridge exhibited exceptional stiffness in all directions.

On January 24th, 1890, the first train was driven across the structure by the Marchioness of Tweeddale, and on the 7th of the present month the directors made a similar crossing.

The opening ceremony is fixed for March 4th, and will be performed by H.R.H. the Prince of Wales.
